The French Mediterranean squadron has just made an interesting experiment with a novel light, the invention of a French naval officer. The sailors call it "the rat-trap light." The squadron left Marseilles on the 20th of August, at five o'clock in the evening, leaving behind the torpedo destroyer Faucon, which was to start three hours later and hunt it up. At eight o'clock the Faucon weighed anchor and steamed out in pursuit with all lights extinguished except this novel affair, the ratière. Nobody on board knew the direction the squadron took, but at one o'clock in the morning the Faucon joined it.

This "rat-trap light" is a thing of small dimensions placed in the stern of the vessel above the wheel. No other light is permitted on board. It throws out an electric light which cannot be seen on the right or left of the ship, and can only be discovered dead ahead under certain conditions known to the seeker. By means of this invention night signals can be made when rockets or flash lights might be useless or liable to betray the position of the fleet to the enemy. It can also guide a squadron in line, with all other lights out, even in dangerous latitudes.

The French navy alone possesses this light, and the Admiralty evidently attaches great importance to it, judging by the precautions that are taken to guard it against discovery. The commander of a ship and one sworn officer alone handle it, and it is kept on board in a special apartment, of which the commander holds the key.

TIED ITS HEAD UP WITH A TOWEL.

A reader of The Electrical Engineer reports that as an experiment he recently tied a wet towel on a 16 candle-power 57 volt lamp. It was an old, much blackened lamp. In 22 minutes the towel began to scorch. In 31 minutes the lamp exploded and the towel ignited.

ALTERNATE CURRENT TRANSFORMERS.—V.

BY DR. J. A. FLEMING, F. R. S.

IT will be seen, therefore, that the total Board of Trade units given in the primary circuit in the 24 hours are 68,734, and the total Board of Trade units taken from the secondary circuit in 24 hours are 60,000. The secondary output is, therefore, 87 per cent. of the primary intake, and this is called the all-day efficiency of the transformer on that old diagram. It is not very far from the instantaneous or actual efficiency of the transformer at one-tenth of full load. It will generally be found that the actual efficiency at one-tenth of full load is a very fair guide to the all-day efficiency on a load having a load factor of 10 per cent. One thing that should be noticed in connection with this part of the subject, is that the iron core losses in the transformer are diminished as the transformer heats up. The curve in Fig. 42 shows the results of an experiment with a 50 kilowatt transformer. The transformer was taken up when perfectly cold, and its core loss was measured and found to be 983 watts. This transformer was then connected with the circuits, and the core loss was taken at various intervals during a period of 20 hours, until the transformer had reached a final constant temperature. It was then found that the iron core loss had fallen to 893 watts. The transformer was then disconnected from the circuit, and allowed to cool, observations being taken during that period. After 24 hours the transformer had again become quite cold, and the core loss had risen up to 983 watts. There is, therefore, a difference of 100 watts, or nearly 10 per cent. in the core loss of the transformer when taken hot and when taken cold. This experiment shows the necessity for defining the conditions under which the core loss and efficiency of a transformer shall be taken; it is not enough to specify simply that the efficiency shall be of a certain value. It must be specified under what conditions this efficiency is to be taken, whether with the transformer cold, or the transformer warm. In addition to this

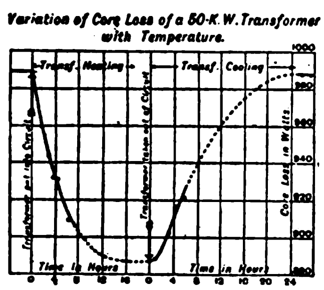

FIG. 42.

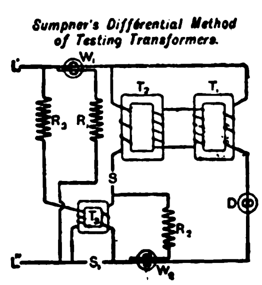

FIG. 43.

there is a variation of the iron core loss taking place with time. When a new transformer, which has never before been used, is connected with the circuits, it is often found that when core loss measurements are made continuously at regular intervals, the core loss goes on increasing, and this may take place to the extent of 40, 50, or even 100 or more per cent. increase. In fact, instances have been noticed in which a core loss has increased in the course of a few months to three times its original value. Mr. Mordey found that he could produce this effect in iron by slow heating. It does not occur in all transformers. In an experiment I specially tried with two new Thomson-Houston 30 kilowatt transformers, which were connected to the circuits night and day for three months, and regularly measured at intervals, no apparent increase in the core loss was found. The reasons for this permanent increase in the hysteresis loss are not yet entirely explained. In the case of some iron which has been very carefully annealed, it is found there is a remarkable rise in the hysteresis loss when this iron was used as the core of a transformer. The same rise is also found in the case of iron which has not been very carefully annealed. We cannot at the present moment state precisely what are the conditions under which this increase in core loss takes place, or what is the constituent in the iron that tends to produce it. It has been supposed by some investigators that the presence of silicon in the iron has a tendency to determine this increase in the hysteresis loss, as the iron is magnetically used. It, however, points to the necessity not only of testing transformers at first, when they are purchased, and before accepting, but of taking a series of tests of the transformer at regular intervals. Suppose that in a sub-station there are three or four large transformers, and that one of these transformers is made the master transformer, and is kept connected with the circuits night and day, the others only being switched on during the time of heavy demand; then it is obviously a very important matter that the transformer, which is thus made the master transformer, should be the one which has the least core loss; and if it should happen that this transformer is one which has largely increased its core loss by use, then it should be exchanged for another which has the least obtainable core loss for that size of transformer. In every substation the wattmeter arrangement described at the beginning of this lecture should be capable of being set up in order to make core-loss measurements in a systematic manner. It is perfectly clear that if a few thousand Board of Trade units more than necessary are being wasted in each transformer sub-station, that the total value of these Board of Trade units when added up and capitalized may realize a very considerable sum of money.

For the purpose of testing large transformers in workshops without requiring a large consumption of power, Dr. Sumpner has devised a differential method of testing, the arrangements of which are shown in the diagram in Fig. 43. In this case the power given out by one transformer on the secondary side is put back into the primary circuit by means of another reverse transformer, so that what is actually taken from the primary mains is merely the total loss in the two transformers. This total loss is measured by a wattmeter arrangement, which enables us to measure, therefore, the efficiency of the two transformers taken together, and, therefore, if they are identical, the efficiency of either of them. In addition to the efficiency tests, there ought always to be a series of security tests to test the strength of the transformer. In the first place, the temperature should be taken after the transformer has been connected to the mains for 24 hours on open circuit, and then connected to the mains for two hours on full secondary load. This temperature is best taken as described in the beginning of the lecture, by measuring the resistance of the copper circuits, but it may be checked by means of a thermometer placed inside the case. Under no circumstances should the temperature in the interior of the transformer rise above 100° C. In the next place, electric pressure equal to double the primary pressure ought to be put on between the primary and the secondary circuits for at least fifteen minutes, and the same double pressure ought to be put on between the primary and case—that is to say, if the transformer works at 2,000 volts on the primary circuit, 4,000 volts should be put on between the primary and secondary circuit for 15 minutes, and 4,000 volts between the primary and case for fifteen minutes. In addition to this, the transformer should be tested for several hours at the normal pressure before being put to work. In the case of large transformers which have stood idle for some time, it is not wise to put on the full primary pressure at once. The transformer should be gradually warmed up by passing a large current through the secondary circuit of the transformer, the primary circuit being short-circuited. In that manner the transformer will be gradually heated up, any moisture which has been absorbed into the insulating material or into the case will be got rid of, and the transformer will be gradually brought into a condition of high insulation. Transformers which have been standing in the stores for a long time may frequently fail if put suddenly on to the working circuits without some such precaution.

OBITUARY.

PROF. LUIGI PALMIERI.

The death is announced of Luigi Palmieri, the Italian meteorologist. He was born in 1807 and began his studies in the seminary of Cajarro. He afterwards went to Naples, where he studied philosophy and natural science. Subsequently he devoted himself to the instruction of young men, and had a private school of philosophy and physics with more than 400 pupils. He was professor of physics in the Marine College at Naples, and afterwards in the University. In 1860 he had the direction of the Vesuvian Observatory. He devoted much attention to electricity and magnetism and for use in the Vesuvian Observatory designed several new instruments, especially two, one for the study of the variations in the amount and kind of atmospheric electricity; another, an electrical seismograph, of which two duplicates have been purchased for use in Japan. Full details of the observations upon the volcanic phenomena of Vesuvius were given in the various reports upon the observatory published by Prof. Palmieri.

HERBERT D. COOK.

Herbert D. Cook, who was drowned at Atlantic City on August 23, was born in 1870, and was graduated from Stevens Institute, in the class of '92. Soon after his graduation he obtained employment as an electrical engineer in the Mermand Electrical Company, of Philadelphia, and had remained in their employ ever since. At the time of the accident he was summering with his folks at Brigantine Beach, near Atlantic City.

CONTENTS.

ILLIBERAL ELECTRICAL ENGINEERS.

SWEEPING charges and indictments against whole groups of men and even nations are very much in favor with critics of a certain type, and such a man, we take it, must be Mr. R. D. Williams, who writes an article in the "American Machinist" in support of the serious accusation against electrical engineers, that they are wanting in "liberality of mind." They have no generous, give-and-take spirit at all. "Each one seems to think that his own little note book contains the final kernel of truth, which it would be suicidal to disclose, and he keeps it carefully hid in his closet." Sadder, still, this is true not merely between rival companies, but between fellow workmen in the same shop. Corroborative detail proving this deplorable state of things is found in the fact that the electrical journals have a paucity of the kind of correspondence that Mr. Williams finds in delicious profusion in mechanical periodicals. Worst of all, he traces the terrible illiberality of electrical engineers to the fact that they are educated men; while the liberal-spirited, broad gauge, give-it-away, tell-you-how-to-do-it-for-nothing men who spend every moment of spare time in writing helpful, whole-soul letters full of shop kinks, came up from the ranks.

One hardly knows just where to grapple with this kind of indictment. It is somethng like that brought by the Western silver man who assumes that all Eastern folk are in a Wall street conspiracy to squeeze his life blood out of him; or that on which a Spaniard acts when he tears down the flag over an American consulate. The best answer to such prejudice is, perhaps, a little reasoning, but the trouble is you cannot always get the indicter to reason with you. Postulating that Mr. Williams is to be argued with, though he draws the conclusion that education is narrowing, which is not the attitude of a very open mind, we would like to point out to him that as a matter of fact the vast majority of men to-day in the electrical field are not those who have been specially trained as electrical engineers in the schools or colleges. It is far too early for that yet. A great many of them were educated as mechanical engineers, some as civil, but the greatest number came up from the ranks of telegraphy and were not educated at all, in the engineering sense. We live in hopes of seeing the time when the proportion of college bred men in the industry will be larger, and we wish to challenge, as positively as we can, the proposition of Mr. Williams that the percentage now is large or that the educated electrical engineers are a narrow, selfish, jealous lot of fellows. Heaven forbid!

Now as to the contention that electrical men have not a superabundant supply of valuable shop kinks that they want to swap with each other through the medium of a mechanical "mart and exchange" journal. There is something in this, but what of it? Mr. Williams instances bicycle factories, as places where this kind of matter is easy to gather. Our experience of bicycle factories is distinctly to the contrary, and we would very much like to witness his efforts in trying to penetrate into certain experimental departments we have seen. In the electrical field it is peculiarly the case that the arts are new, much is still patentable under the laws of the land, and it costs no little time and money to learn new facts and principles. One of the great reasons why electrical companies and inventors have not reaped a fair reward is that they were not able to protect themselves after years of effort and expenditure; but Mr. Williams would apparently let the bars down altogether and abolish the patent system, so far as electrical engineers are concerned. Mr. Edison dealt with this very subject the other day when he said: "I discover a great many things I would be glad to give to the public for nothing, but I don't dare. I patent these things to save myself from defending lawsuits. There are a lot of sharks in this world who are continually on the lookout for new things, and when one of them hears of something new he hustles to the patent office to see if it is patented. If it isn't, he claims it as an original dis-

covery and files his claim. Then he will turn right around, and, like as not, begin a suit with the man who invented the thing for making use of it. The inventor will say: 'But I discovered this thing first; I am the inventor.' He is referred to the patent office, where he finds the official claim of original invention. The fact that the papers are filed long after he made his discovery does not help him, for all the other man does is to hire a fellow to swear that he made the discovery a month or two prior to the date the inventor claims. It sounds ridiculous, probably, but it is a fact that there are often races between the inventors and the sharks to reach the patent office, the sharks having had early information about the inventor's discovery. There are many such races, and thousands of dollars depend on each one. What I say is literally true."

Mr. Williams might reply to this that he was attacking, not inventors, but electrical engineers. It makes no difference. A professional man does not slop over all the time in letters to the journals. Architects, civil engineers, lawyers, doctors, and others, are not by any means more communicative than electrical engineers, if as much so; and they would object, as we do, to any test of a man's liberality of mind, based on his readiness to unload "hints" and "kinks" and "wrinkles" and "chips" from his own experience, for common consumption.

In conclusion, it is but fair to electrical engineers to mention a fact with which Mr. Williams may not be familiar, but which is highly pertinent. A great many electrical engineers are in the employ of large corporations, and are not at liberty to divulge what they learn in the factories or laboratories, or to publish news as to novelties. In numerous instances they are under contract to convey to their employers any new invention they may make. This system is not peculiar to the electrical industries, nor is it in them limited to the factories. The telephone and telegraph companies are willing to allow their skilled men to take part in ordinary discussions, but have a well understood and rooted aversion to the printing of any of the methods and apparatus they have made their own. We think that this policy might sometimes be more liberal, but it often has warrant, and it is at least certain that the electrical engineers are not to blame for it.

NEW YORK STREET RAILWAY CONVENTION.

It is a sad thing to contemplate that companies engaged in a legitimate industry, catering to a public want, and furnishing service better and cheaper than has ever been done before in the history of the world, should be compelled to band together for the purpose of resisting unjust encroachment on their rights and privileges from the Legislature selected by themselves and their patrons. Yet such is the fact, and the result has been the organization of electric light and electric railway State associations, most of which have attained vigorous growth. Among the latter the New York State Street Railway Association, which held its annual meeting last week, is one of the most active and valuable to its members, as will be apparent by a glance at the papers and proceedings of the Binghamton convention, which we publish in this issue. Organized primarily for protection against legislative "strikes," the mere fact that during the last session of the New York State Legislature 140 bills relating to street railways were introduced, is sufficient proof that the association has a raison d'etre to an eminent degree, and plenty of work to do to ward off the animosity or cupidity of dishonest Assemblymen against railway, telephone and other public corporations. The work accomplished in this respect by the association's officers and counsel in the past year has been well rewarded. But outside of the work of self-defence in which these State organizations are engaged, the meetings also, as a rule, serve to bring out papers and discussions on railroad management and operation which are of the highest value, and this last convention is an eminent example of the usefulness of such an association to its operating members. Every paper read contained one or more valuable suggestions, and several contained information of the highest practical value. Take for example that by Mr. F. O. Rusling, on the use of old rails as underground conductors. There is scarcely a road of any size which has not from fifty to several hundred tons of old rails in its scrap pile, and one can hardly imagine a better use for them than as conductors to supplement present feeders. The cost as compared with copper is largely in favor of old rails. As regards the question of resistance at the joints that seems also to have been satisfactorily solved, according to the experience of Mr. Rusling, so that unless the lapse of time should develop some change in the present condition of the work done by him, the old rail may yet figure as a prominent and useful factor in electric railway work.

Passing from old to new rails, Mr. C. S. Allen in his paper points out the very important position which the high-carbon rail is destined to occupy in street railway work, as well as in steam railways. The tests which he mentions as having proved satisfactory on the New York Central have been confirmed by a similar one of street railways in Brooklyn and elsewhere, so that there is little doubt of the manner in which many future specifications of street railway rails will read.

Probably as important a question as any of those brought before the convention was that relating to the distribution of power from trolley circuits. Waiving the objections raised to this form of distribution by the Fire Underwriters, the author of the paper aims to prove that power can be distributed more cheaply from railway circuits than from electric light and power circuits. We believe this to be an open question. If the author meant to compare the efficiency of generation possible with the modern high class apparatus installed in street railway stations, with the older and less efficient apparatus in the many electric light stations, without taking into consideration other items, it would be conceded that the comparison would be in favor of the electric railway. The electric railway, it is true, has the advantage in the ease with which connection can be made to its conductors, when these are overhead, as they are in the majority of instances. The distribution of power is a development which railway companies should go about very deliberately. Nothing, we take it, ought to be allowed to interfere with the operation of the road by any company having its own interests at heart. While it is true that there are in most cities periods of light loads at the station, a great many conditions arise to put full or abnormal loads on the system, aside from the regular periods of full loads. At such times any extraneous load, such as that from power motors, would be a drag on the system, and would, in all probability, occasion a breakdown, or, at least, a serious interference with the regular operation of the road. Then, again, we think it is rather the rule than the exception that railway feeders are not made any too heavy for their work, and hence even if made sufficiently heavy to carry the normal full load there would be nothing to spare to carry the stationary motor power load which might be connected to the circuit. It is here that we believe the most serious trouble will be found. There may probably be instances where small roads might derive a profit from such a stationary motor service, but we are pretty certain that no large company valuing the character of its service can afford to undertake this class of work. We have, of course, not touched upon the legal aspect of the subject as to the right of street railway companies to enter into this class of business, but aside from that, it would be better on all accounts for street railway companies to leave this work to those to whom it naturally belongs, the electric light and power companies. We believe a good deal of friction and unpleasantness will be avoided by adopting this course.

A COMPRESSED AIR CAR.

Just before his departure for Europe, M. Abdank-Abakanowicz, who has been over here from Paris studying the street railway situation, was interviewed by the "Evening Post," when he made statements as to compressed air traction in his own country, confirming the intelligence on the subject received by ourselves. He said: "I confess that I did not examine the cars you have in operation here on One Hundred and Twenty-fifth street; but the reason is that, as an engineer, I have studied the principle thoroughly and know that it is incapable of any substantial development. So far as I have heard, the only difference of any moment between the air motors here and those in France is that here you propose to operate under a very much higher pressure of air than we use there. But this, while not increasing the efficiency of the system to an adequate extent, and not removing the objections founded upon complexity and cost, is highly dangerous. With the much lower pressure used in France we have had many accidents. Tanks, pipes, and valve-boxes have at one time or another exploded. I have personally seen two explosions. What would be the result with the pressure doubled? Since the practicability of the trolley was demonstrated there has not been a single compressed air line added to those already in France." It is understood, we might add, that the cost of compressed air operation in Paris has also been enormous.

It does not follow, however, that Paris will have the trolley, except in outlying districts, any more than it will resort to the cable, which M. Abdank considers also as doomed. Hence we may look for some underground conduit work in Paris, and perhaps storage battery cars, though they are not in favor there. The fact that the omnibus monopoly in Paris expires at no distant date, when a new contract with the city will be necessary, will without question inaugurate a new regime of mechanical traction in that city, when electricity will "be in it" very emphatically.

Roentgen Rays.

THE PHYSIOLOGICAL EFFECTS OF THE ROENTGEN RAYS.

BY H. D. HAWKS

IT seems that all of the properties of the X-ray have not yet been discovered; among the latest is the physiological effect. With the powerful apparatus now used, experimenters are beginning to find that it affects the system. During the early part of July I carried on a long series of experiments with an extremely powerful apparatus. At the end of a few days I found that the rays were having quite an effect upon me. At first the skin began to dry and to itch, all the moisture being taken out of it; I paid no attention to this, but continued to work. After a little longer exposure my hand, which was the part most exposed, began to swell, the inflammation being in the hand for about ten days; at the end of that time the swelling rapidly went away, but the skin all came off, just as with a sunburn. The joints and finger nails seemed to suffer most, the joints becoming nearly transparent, and the nails killed, as new nails have since grown. Wherever the hair was exposed to the ray it fell out, but it does not seem to be permanently injured as it grows again as the skin gradually returns to a healthy condition, but the growth is very slow. In my case it was eight weeks after the exposure before it started to grow. The eyes were also very badly affected, where not covered by the lids. The exposure to produce such effects as these probably amounted to between two and three hours.

As to what produces the burn, I think it is purely an electrical effect, and that the ray has nothing to do with it, except in a peculiar manner; the burn is such as would be produced by a combination of heat and light, as sunburns. Now the light is supplied by the ray, and the heat, I think, is due to electrical conditions, that is, there may be an invisible electrical shower that comes from the tube, the air may be full of very small electrical sparks that we do not perceive in the ordinary light, but as the room is darkened we can begin to see this shower. Anyone that has held his hand before a tube has experienced the same sensation as when the hand is held near a high potential electrode, and if held close and the room is dark the shower of sparks can actually be seen. As far as I have experimented, any electrical conductor placed on the hand will prevent the burning action.

Summing up I will say that the effects seem to be confined to the skin alone, and consist principally in the drying up of the oils in it, which produces all of the effects on hair and nails as noted, and none of these effects are permanent, but disappear when the skin becomes healthy again.

LODGE ON ROENTGEN RAYS.

The mode by which light and Röntgen rays are able to bring about the discharge of an electrified surface has been discussed by Dr. Oliver Lodge in "Science Progress." Experiments were carried out by him with the object of testing the presence of metallic particles or vapor near an electrified metal rapidly discharging under the action of light. The results lead to the conclusion "that the discharge of electricity from illuminated surfaces is not effected by evaporation of those surfaces, but that the molecules, which convey the charge, belong to something in the gas, and not to the illuminated body." It is suggested that the discharge of an electrified surface by Röntgen rays—an action which seems to be brought about by the conversion of the gas, or other insulating material, near the charged body into a conductor—is probably effected "by dissociating the substances into charged atoms which are then free to act as carriers, and speedily convey to a distance the charge of an electrified body by journeys along the lines of force. It may be that ultra-violet light acts in somewhat the same way, but not in exactly the same way." As to the nature of the rays, everything now indicates them to be transverse vibrations, and Dr. Lodge thinks their wave-lengths are not much greater than the size of atoms.

X-RAY PHYSIOLOGICAL EFFECTS.

With regard to certain features of X-ray physiological effects, Mr. G. A. Frei, of Boston, writes us: I am inclined to think that a continuous application of from one to two hours will start the effect. In my case it was an application of about 10 or 15 minutes a day for about a week before I could notice the effect. At first the skin becomes brown the same as sunburned, then the hand begins to swell and the color turns blue. In my case water blisters were raised, one of the ⅜-inch diameter. At times there is a burning, itching feeling for a few minutes then the pains disappear again. The swelling increased for several days till I decided to stop experimenting on my own hands. I had sufficiently demonstrated the effects of the rays as far as I was concerned. Three or four days after I stopped it began to improve. The skin peeled off; I should say I took off three layers. At that stage I was obliged to test three tubes and thoughtlessly I exposed the same hand for about a minute or a minute and a half. This completely stopped all improvement for a number of days. At present my hand is nearly in good condition again. It would undoubtedly be interesting to know what the ultimate result would be, yet I do not care to use my own hands for the experiment, especially as a hand showing the X-ray treatment is not a thing of beauty."

EXPERIMENTS WITH ROENTGEN RAYS.

ACCORDING to telegrams in the daily papers, at a psychological congress at Munich there has been a Röntgen ray demonstration, at which a "living human body (why not say a man and save two words of the telegram) was placed under the action of the rays," and observers were able to watch the action not only of the osseous parts of the body, but also of the diaphragm, stomach, and heart. How it was done is not said, except that it is mentioned that "specially prepared tubes" were used. Probably higher vacua than usual and an extra high voltage were adopted. In this connection it would be interesting to know what is the precise effect of using anodes of less density than platinum on the penetrating power of the rays and varying the nature of the residual gas in the tube. The latter ought to have a very considerable influence on the result, but it must be remembered that though theory may give some hints as to the way to get a particular kind of wave length, there is also the question to be considered of whether the fluorescent screen or the photographic plate will respond to it. Lastly, it has been gravely announced that a discovery has been made—and made in Germany, though not at Munich—that the aurora borealis is caused by Röntgen radiations emitted from the sun making the air fluoresce. That the aurora is seen at night does not seem to have occurred to the discoverer. It is really quite remarkable how a subject like the new radiations, which obviously required in anyone dealing with it some acquaintance with the conceptions of physics, should from the beginning have been selected as a happy hunting-ground for that numerous class of people who, being without clear ideas in the matter, are as fertile in suggestions as they are incapable of understanding the experimental proofs of their futility. But perhaps even this is not more remarkable than that the really eminent persons who interested themselves in the subject did not sooner see that phenomena which were as familiar to them as their alphabet were entirely fatal to the original hypothesis of longitudinal ether vibrations.—London "Electrical Engineer."

Letters to the Editor.

THE THREE-WIRE PATENT IN THE U. S. AND ENGLAND.

We learn that the three-wire Edison patent has expired in England. Should this information be correct, will not such expiration have effect on the patent's life in this country? We would be very glad to receive any advice on this subject.

Sept. 2, 1896. THREE-WIRE.

The three-wire patent which expired recently in England was that issued to Dr. John Hopkinson. So far as we are aware, no foreign patent on the three-wire system was taken out by Mr. Edison prior to the U. S. patent, and hence the U. S. patent is in nowise limited by the foreign patents.—Eds. E. E.

Patent Notes.

U. S. PATENT OFFICE STATISTICS.

A total of 24,585 patents granted and trade-marks, labels and prints registered by the government during the year is shown in the fiscal year report of the Commissioner of Patents, submitted to Secretary of the Interior Francis this month. Of these, the patents, including reissues and designs, numbered 22,791, and trade-marks 1,782. There were 48,105 applications received, 41,668 being for letters patent alone.

The number of patents which expired was 11,166. The number of allowed applications which were by operation of law forfeited for non-payment of the final fees was 4,014. The total receipts were $1,307,090, the receipts over expenditures $209,721, and total receipts over expenditures to the credit of the patent office in the Treasury now amounts to $4,776,479.

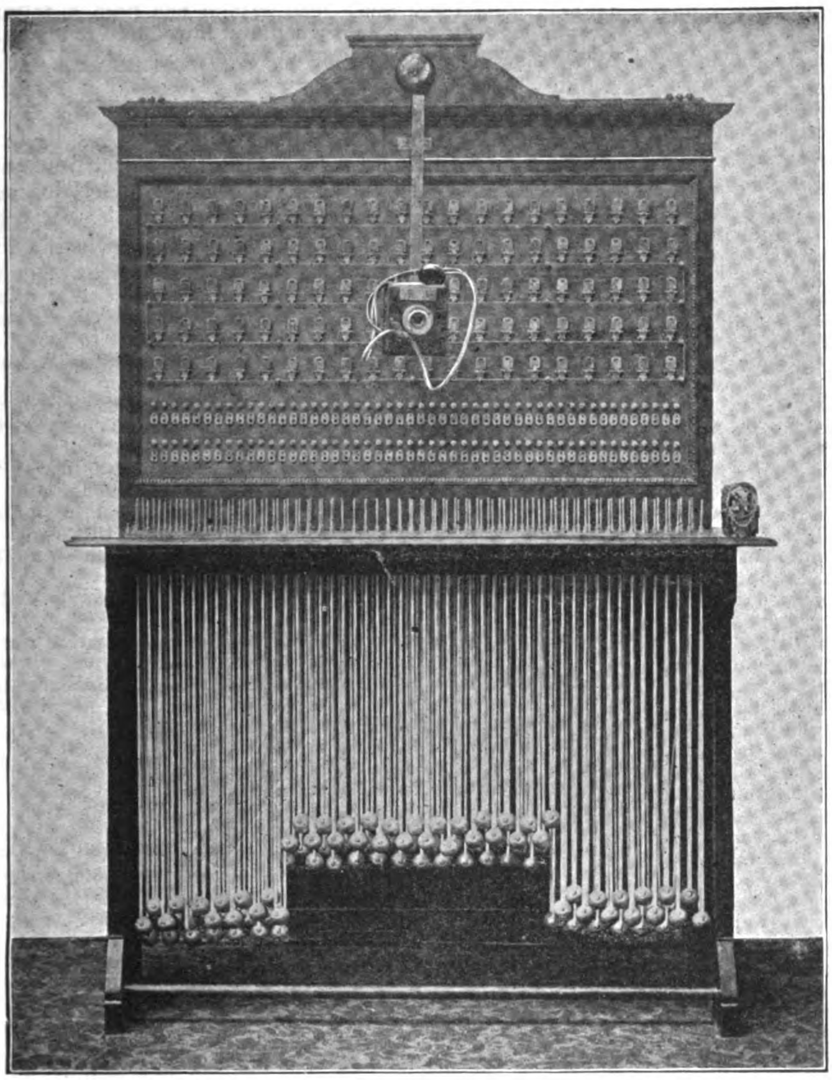
TELEPHONY AND TELEGRAPHY.

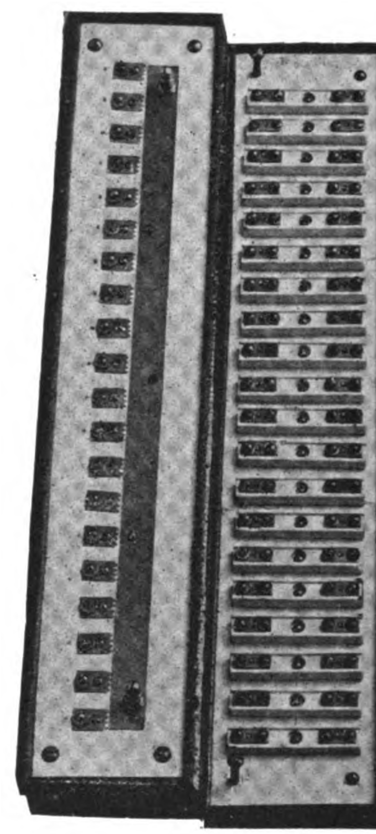
THE MISSOURI TELEPOHNE MFG. CO'S. IMPROVED SINGLE PLUG SWITCHBOARD AND LIGHTNING ARRESTER.

THE accompanying illustration, Fig. 1, represents an improved central telephone station switchboard, invented by Mr. E. L. French, superintendent of the Missouri Telephone Manufacturing Company, St. Louis, Mo. The most striking feature of the board is the large number of plug cords. Each subscriber has a drop, and the continuation of the drop to complete its circuit has a plug cord. The base of each plug is a brass button, which is pulled down tight to brass bars running across the switchboard table, and by the aid of the lead balls, which have a hole through them, threaded on a sistance and serves as a clearing out coil when the two subscribers are through talking.

The jacks used in connection with this board are extremely simple. The plug breaks the connection from the drop to the plug cord. The plug holes, which are on the face of the board, are all shunts, and when any plug is inserted in any plug hole it has a direct connection to the line without going through any coil. Another important feature is the easy adjustment of this board. Mr. French claims that he can place a 200 drop switchboard in a space 6 feet wide and leave plenty of room for renewals and adjustment. This board is said to possess other mechanical and electrical improvements, which render it very efficient for quick and accurate service.

The illustration, Fig. 2, represents the company's switchboard lightning arrester, which is claimed by the manufacturers to positively protect the apparatus against damage from high-tension electrical currents as well as against lightning.





FIGS. 1 AND 2.—SWITCHBOARD AND LIGHTNING ARRESTER, MISSOURI TELEPHONE MANUFACTURING CO.

spiral-braided plug cord, the current travels its course to the ground. This feature, of having one plug cord for each subscriber, is claimed to be an important improvement. Each plug is numbered, and the operator with a little experience can familiarize herself, and quickly lay her hand on any plug desired.

When a subscriber desires a connection the operator takes the plug corresponding to the drop and touches it to the operator's bar, which is a long brass bar running the full length of the table of the switchboard. This throws her receiver and transmitter in circuit with the subscriber, and she finds the number desired; then by simply inserting the plug in the plug hole of the number called for, the connection is made. When the plug is inserted it cuts out the drop coil of the subscriber and leaves only one coil cut in on the line between the two subscribers conversing. This coil is wound with very low re-

In its design and construction one of the most important objects aimed at was to so distribute the wires that any one could be readily accessible without interference with any other.

The framework of this arrester is constructed of hard wood, and is painted with an insulating compound, which renders it an insulator itself. On the face of the board are mounted the fuse blocks, and the lightning jaw teeth are protected with ¼-inch asbestos. The line wires run direct to the fuse blocks, thence to the switchboard. Each wire is tapped for connection with the lightning arrester, the terminals of these tap wires being represented by the line of serrated brass jaws, which are set 1-16th of an inch from the ground bar. By this arrangement the lightning discharge will jump the space between the teeth and the ground connection.

The fuse blocks afford protection against high-tension cur-

rents and are not designed to avoid the damaging effects of lightning, the lightning arrester taking care of that. The two systems of protection, however, give a combination on one switchboard, that is claimed to be absolutely reliable in its action. The Missouri Telephone Manufacturing Company has equipped some of the largest exchanges in the United States with these boards.

The board is simple in construction and durable, and the company maintains it in working condition. It is stated that operators in exchanges equipped with these boards have so much confidence in the apparatus that they do not leave their seats at the switchboard during thunderstorms, as is frequently done in exchanges having the ordinary protective devices.

The Missouri Telephone Manufacturing Company will have a display of its apparatus on the main floor of the St. Louis exhibition this year, and informs us that it is the only electrical concern that has been admitted thereto.

A PLEASANT PICTURE OF PROF. BELL'S COUNTRY LIFE.[1]

BY GRANT HAMILTON.

EVERY summer a great many American tourists "discover" Baddeck, and every one of them is surprised to find that Baddeck was enshrined in American literature twenty years ago by Charles Dudley Warner. He is still more surprised to find that one of the best known citizens of the United States—a man whose name is on every tongue—has an estate in Baddeck of magnificent proportions and spends there in cool content the summer months.

Baddeck is a sleepy old village on one of the chain of lakes which connects upper and lower Cape Breton Island. Bras d'Or Lakes they are called. Many of them are rather arms of the sea, reaching in from the coast near Sidney in long, narrow strips, which broaden through slim estuaries into beautiful lakes dotted with pretty wooded islands.

It was on an exploring trip through the lake region that Professor Alexander Graham Bell, the telephone inventor and millionaire, found Baddeck six or seven years ago. He was traveling with Mrs. Bell and her parents, Mr. and Mrs. Gardiner H. Hubbard. They stopped at quaint Baddeck, became fascinated with its quiet, its simplicity, its beautiful surroundings, and Mr. Bell determined to make it his summer home.

Mr. Bell does not do anything by halves. Admiring the mountains about Baddeck, he bought one and created an estate on which he has spent not less than $250,000 on improvements. Roads have been laid out, making magnificent drives, and a $35,000 house has been erected. It is a double house of frame, from which a great brick chimney rises, telling of a big fireplace and a generous log fire in the reception hall. There is a tower at each corner, and across the whole of the broad front stretches a veranda. As far as the eye can reach from this veranda stretches a panorama of mountain and valley and lake. Cool breezes blow across the mountain all the summer days, and every night is cold enough for fires and blankets. For neighbors Mr. and Mrs. Bell have George Kennan, the Russian traveler, and his wife, warm friends of theirs. For company there are many friends, to whom both the Bells and the Kennans extend a hearty hospitality. For occupation there are sports in season, the beautiful drives around Mr. Bell's thousand acre estate and work in the laboratory which Mr. Bell has built.

Mr. Bell calls his estate Beinn Bhreagh. A tugboat brings it in communication with Baddeck, and also furnishes the motive power for the houseboat, Mabel Beinn Bhreagh, named after Mrs. Bell, in which the Bells make frequent tours of the lakes. In the shooting season Mr. Bell and Mr. Kennan occupy a pretty little hunting lodge twenty-five miles inland. Very near Baddeck is the Margaret River, one of the finest salmon streams in the provinces. There is no lack of sport when the season opens, in the middle of September.

All the days are calm and peaceful in Baddeck. Farming, fishing and sheep raising are the chief occupations of the people of this country. There are no factories or saw-mills, and the few stores in the little town have a sleepy look. But it is less sleepy than it was in Mr. Warner's time. The Bells and the Kennans have labored earnestly to improve the condition of the people. Mrs. Bell has had teachers and materials brought from Boston to teach the wives and daughters of the fishermen to make lace, like the peasants of that older Breton in France. Mr. Bell has helped open a sale for the carpets which these women weave. A kindergarten school has been established through their efforts. There are classes in literature, and a current events club for the wives and daughters of the merchants of the little town. For the men Mr. Bell has founded a workingmen's club and Mr. Kennan a free library. Communication between the farming region and the lakes has been made easier by the roads Mr. Bell has built, and altogether the country about Baddeck is more prosperous and happier for the coming of the wealthy inventor.

[1] Abstract.

BELL TELEPHONE OUTPUT.

It is said that the instrument statement of the American Bell Telephone Company for the month ending August 20 has not been favorable, many instruments having been returned. The cause of the large gain in instruments outstanding the past six months, nearly 125,000 increase, is said to have been due largely to the change in the method of telephone charges, the introduction of the party line and the measured service systems. The party line system has not been a complete success, except perhaps in the suburbs. Its principal disadvantage is the continual ringing of the telephone bells in houses, two to five residences being on the same line, and the natural mistakes arising therefrom. The system has been a failure in Boston, it is said, although when first introduced it was largely adopted by physicians and attorneys.

THE KILDISCHEWSKY TELEPHONE.

A special dispatch from London, of September 8, says: The "Daily News" will to-morrow publish a dispatch from Odessa saying that M. Kildischewsky, an electrician, has discovered an improvement in the telephone by the use of which distance has no effect upon the hearing. In a recent experiment between Moscow and Rostoff, on the Don, a distance of 890 miles, talking, music, and singing were heard with perfect distinctness. An ordinary telegraph wire was used. The dispatch adds that M. Kildischewsky will go to London to experiment with his improvement on the Atlantic cables between London and New York.

Commenting on this, Mr. F. A. Pickernell, the engineer of the American (Long Distance) Telephone and Telegraph Company, said:

"I see it is stated that he has talked over 890 miles of wire. Why, here in this country we have a telephone circuit 1,400 miles long in commercial use every day, and I have talked over 2,200 miles, nearly three times as far as this man. The line he experimented on is really a very short one, and I see nothing in his achievement to boast of."

"But he used an ordinary telegraph wire," suggested the reporter.

"Well, we use copper wire, exactly the same as that used by the Postal Telegraph people for their main lines. I would be the last man in the world to seek to minimize another's invention, or to say it is worthless. But there is nothing in this account to indicate that he has anything of importance. He has probably got a new transmitter and thinks it beats the world. Now, I have made telephony my life work, and am not exaggerating when I say that Americans are far ahead of Europe in long distance work. I designed the line from New York to Chicago, which was twice as long as any then in use, and to-day our line from Boston to St. Louis, 1,400 miles long, is more than twice as long as any European telephone circuit. Our line to Memphis is 1,588 miles long. These lines are in commercial use, and people pay their money to talk over them, while the Russian's 890-mile line is only an experiment. The foreign governments owning the long distance telephone lines in Europe in fact have adopted American methods and plans for operating them."

"Do you consider it feasible to telephone across the Atlantic?"

"All experiments indicate that there is no possibility of this. I made some calculations once and found that it would be necessary to have a cable as thick as a hogshead to carry the voice so far under the ocean. The Lucania, Campania, and all the big steamers couldn't lay such a cable, even if it was made, and the cost would be several hundred times that of an ordinary cable. The telephone line from London to Paris is the one they boast of in Europe. It is 290 miles long and has 20 or 21 miles of submarine cable. I have talked over 23 miles of submarine cable. It was on a government cable and the line connected Nantucket and Boston. That is about the limit of successful submarine telephony."

KNOXVILLE, TENN.—According to the Knoxville Morning "Tribune," the local People's Telephone Company, which makes its own equipment and pays no royalties, now has 600 paying subscribers on its list, and is reaching out into the country with the intention of connecting up points 100 miles distant. The officers are: C. E. Lucky, president; W. L. Welcker, vice-president; J. C. Duncan, general manager; F. J. Milligan, secretary and treasurer.

ELECTRIC LIGHTING.

A SUBSTITUTE FOR SHUNTS AND MULTIPLIERS ON WATTMETERS.

BY B. D. FRANKENFIELD.

A GREAT deal has been said about shunting the current coils of wattmeters and using multipliers in series with their pressure coils, to increase their measuring capacities. There is another method which others than the writer have, no doubt, originated and used, but which he has never seen in print.

Suppose we have two or more wattmeters of small capacity. Connect their current coils in parallel and their pressure coils in series. Let the current capacities be C_1, C_2, C_3, etc.; the pressure capacities, V_1, V_2, V_3, etc., and let the resistances of the pressure coils be R_1, R_2, R_3, etc. Let the angle of lag between pressure and current be ρ, and suppose that the instruments are all of negligible time constant. We now have a system with a current capacity and a pressure capacity equal to the aggregate current and pressure capacities of the individual meters, but the number of watts it will measure is greater than the aggregate as is shown by the following equation:

$$\text{Maximum watts} = C_1\,V_1\frac{R_1+R_2+R_3}{R_1}\cos.\psi + C_2\,V_2\frac{R_1+R_2+R_3}{R_2}\cos.\psi + C_3\,V_3\frac{R_1+R_2+R_3}{R_3}\cos.\psi.$$

When the meters of the system are all alike the equation becomes

$$\text{Maximum watts} = n^2\,C_1\,V_1\cos.\psi$$

where n is the number of instruments in the system.

For direct current work or for resonant alternating currents, the term cos y becomes unity, and the equations are then:

$$\text{Maximum watts} = C_1\,V_1\frac{R_1+R_2+R_3}{R_1} + C_2\,V_2\frac{R_1+R_2+R_3}{R_2} + C_3\,V_3\frac{R_1+R_2+R_3}{R_3}\text{ etc.,}$$

$$\text{and maximum watts} = n^2\,C_1\,V_1$$

This method can be used with as many as three wattmeters, but with a greater number would be cumbersome. So far as current affects the readings, it is as accurate as a single shunted wattmeter calibrated with its shunt, and, in some cases, more so. If the instruments are unlike and the scales not uniform, errors of personal equation are liable to have less effect on the total energy measured, and if the observer reads one instrument too high and another too low, as might be the case with a direct reading instrument, such as the Thomson or Weston, coupled up with a zero instrument, like the Hoyt or the Siemens electro-dynamometer, the errors of personal equation would be compensating.

So far as pressure affects the readings, each pressure coil acts as a multiplier for the others and an error in reading would be multiplied just the same as in the case of a single meter with a multiplier. The graduation of the scales might here be a consideration as well as the types of wattmeters used. When like instruments are used, a very accurate determination can be made by averaging the corrected readings and multiplying by n^2.

This method can be used with shunted instruments or with a single shunt around the whole system, but the corrections would be complicated. However, it might sometimes be convenient to use a multiplier in series with the pressure coils when testing on voltages higher than the aggregate voltage of the instruments.

Here is an illustration of the convenience of the method: There are two wattmeters in a certain laboratory, each of 110 volts by 10 amperes, and the aggregate number of watts they will measure is 2,200 on a circuit whose power factor is 100 per cent. It is desired to measure a power of between 2,200 and 4,400 watts on a 220 volt circuit. Connect the current coils in parallel, the presurse coils in series, and you have it. If the instruments are alike multiply the average of the corrected readings by four; if not alike, measure the resistances of the pressure coils and correct as in the above equations.

A STANDARD SYSTEM OF LETTERING AND ARRANGING CIRCUITS.

BY JAMES H. BATES, M. E.

THE crucial problem of the construction and maintenance of plants is that of easy and quick handling of circuits—for repairs and renewals more than for installation.

This, it has always seemed to the writer, might be more systematized than it is even in the case of the most common systems of distribution, namely, continuous current two or three wire and single phase alternating current systems. In other words, there should be a fixed standard method for all kinds of systems, for this in the case of circuits of more than two wires (such as in polyphase alternating and four, five or more wire continuous current systems now coming into use) will soon be indispensable.

This article is to suggest how easy such a matter can be in spite of any apparent complication. To start with, let us take the two-phase alternating system with its four wires. Here one has only to call the poles of the dynamo and the conductors therefrom A, B, C and D, and to have the maker so mark wires that a workman will at a glance know whether a wire is an A, B, or something else. There are many methods of marking possible, but the best probably are the two following: 1. A different braid or tape for each letter. 2. A stamp for the lead cover such as a letter at convenient intervals.

In the case of other systems mark as follows: Alternating system, single-phase, A and B; three-wire two-phase, three-phase and monocyclic, A, B, and C; continuous current systems, four-wire, +, B, C and —; five-wire +, B, C, D and —, respectively, from extreme positive conductor to extreme negative one. To still farther simplify matters arrange the wires vertically, A over all, B, C, etc., in regular order below. This can be represented graphically by the accompanying table in which the space containing the letter or sign represents a duct under ground or air space overhead.

Continuous Current Systems.				Alternating Current Systems.		
2-wire.	3-wire.	4-wire.	5-wire.	2-wire, 1-phase.	4-wire, 2-phase.	3-wire, 2-phase, 3-phase and monocyclic.
+ —	+ ± or B. —	+ B. C. —	+ B. C. D. --	A. B.	A. B. C. D.	A. B. C.

LITERATURE.

MODERN EXAMINATIONS OF STEAM ENGINEERS.—By W. H. Wakeman. New York, 1895. American Industrial Publishing Co. 272 pp.

This book is written with the object of giving information to those engineers who wish to qualify themselves to pass the examination required for taking out license to run stationary engines in localities where licenses are required. The work is divided into 53 chapters, which, after giving a general outline of the requirements for the several classes of licenses, take up the various parts of the steam plant which are treated from a practical standpoint. Beginning with the steam engine the values are first discussed and the following twelve chapters explain in a clear manner the various parts of an engine, how they should be designed, adjusted, etc., and also the various types of engines. This part of the book contains numerous numerical examples of the calculations of various parts, horse-power, weight of flywheels, and other essential factors of an engine, which puts the subject before the reader in a manner that is easily understood.

Under the subject of boilers, the safe working pressure, strength of seams, bracing and other requirements are treated and mathematical examples are given. After covering the subjects of piping, exhaust steam heating, strength of materials and other allied subjects, the book concludes with 300 practical questions in regard to the matter contained in the text, with references to the pages where the answers are to be found. The information contained in the book will prove very useful for engineers desiring to pass the examinations required to obtain licenses.

ALDEN'S LIVING TOPICS CYCLOPEDIA. New York, John B. Alden. Price, 50 cents per volume.

The bound volumes of Alden's Living Topics magazine are published under the above title, and an appendix at the close of each volume includes important items preceding close to the date of publication. The scheme of the book is quite novel and consists of a brief and concise treatment of the topics and persons of the day. It covers a wide range of subjects, but makes a special feature of biographical information and modern events of general interest. As it contains only current material, the desirable information it offers is thoroughly up to date.

ELECTRIC TRANSPORTATION.

RATING OF ELECTRIC RAILWAY APPARATUS.[1]

BY W. J. CLARK.

WE all know that in street railway operation there is not the necesity for the full and constant study of the standardizing rolling stock that is being carried on by the master car builders and master mechanics of the steam roads. But in the practical operation of a street railway different conditions exist from these met with in the operation of a steam road, so you must view the special features of your business from a different standpoint than they. Unquestionably it would operate to your advantage, as it would most certainly to the electrical manufacturer, if some definite positive rule for the rating of all of the electrical apparatus were fixed. It makes but little difference what this basis of rating is, provided it is universal, well understood and thoroughly insisted upon by street railway men; and I wish to be distinctly understood as not advocating the particular method of rating which has been followed by the corporation which I represent, but I do most emphatically place myself on record as being in favor of some system to be evolved through the wisdom of the street railway fraternity, and based upon such methods as may seem most just to them, which will fix definitely what a motor of, say, 25 horse-power or 800 pounds tractive effort is, or what, for instance, constitutes a 500 kilowatt generator, and of even going farther than this and define the capacity of switches, circuit breakers, and kindred devices.

No one can suffer from such an arrangement which is entirely just to both the manufacturer and user; and with the adoption of such a rule the little remaining mystery concerning the practical side of electrical apparatus would disappear as it should do.

The electrical manufacturer while justly entitled to much credit for the advancement of the science, and the making of electrical railroading practical, has many sins to answer for under this heading of mystery, and the only power on earth which can absolve him from his remaining sins of this description is the united action of the users of his product to define distinctly and clearly what his product shall be called. And it makes no difference to him whether some particular article of his production is called a horse or an elephant, providing his competitors' production, which should do the same work, is similarly designated. But, if he uses the term horse, and his competitor that of elephant, he is of course at a great disadvantage. While the purchaser who may not be thoroughly conversant with the different terms as applied may supposedly buy the larger animal, and when too late, discover that he has only secured a moderate sized pony.

The manufacturer who has used the larger term is not altogether to blame either, for, no class of machinery has ever yet been produced which was susceptible to so many different methods of rating as electrical apparatus, and all of which may be considered honest, all such methods being entirely dependent upon the standpoint from which its producer views the matter; as, for instance, one producer may say, I will rate a certain sized generator so that it will give a product of 300 kilowatt continuously, and never rise to a dangerous limit of heating, so he calls this a 300 kilowatt machine. Now this very machine would, for instance, develop, say, 400 kilowatt capacity for a period of two hours without rising to a dangerous degree, so some other manufacturer says that in practical operation no generator ever had a continuous load, up to its rated capacity, so a safe basis to go on is to rate the machine at what it will do for two hours, and he calls it a 400 kilowatt. The natural sequence is that some one buys a machine that is either larger or smaller than what they supposed they were purchasing, and if they are fortunate enough to escape paying more money than they should for a certain capacity machine, they are exceedingly liable to get tangled up on the proper sized engine unit to go with the machine and following in the wake of the transaction is the old story of engines being found too large or too small for the generators which they are coupled with. For this trouble, our brethren of the engine trade are not by any means guiltless; for, as some of you have learned by experience, methods of engine rating are about as flexible as those followed on generators; and I trust that I will not be accused of giving away State secrets when I say that instances have come within my observation, where the engine man and electrical agent have stood in together to make it appear to some prospective purchaser that he was getting at least all that he paid for in both engine and dynamo capacity. These evils have of course not troubled the larger roads, with their skilled engineers, so much as they have the smaller roads, and the newer ones which were about to begin business; yet, it is unquestionably wise and just that all opportunities for mistakes, misunderstandings and misrepresentation on such features should be forever done away with.

What has been said on generator rating applies with equal or even greater force to the rating of street car motors; for even greater differences exist in defining their capacity than is met with in generator practice. In fact, the varying features necessitated by the construction of motors for various characters of service, furnish greater opportunity for mystery than in connection with stationary machines, and the best of engineers are occasionally imposed upon by misused terms in connection with some particular class of motor, consequently some definite rule is even more necessary for their rating.

For both generators and motors it is imperative that there be some prescribed rule as regards the character and method of their insulation. In natural sequence to the question of motors comes that of car wiring. It is customary with all the manufacturers of car equipment to furnish a liberal quantity of good material for this purpose, and as to a great extent the work of installing the same is done by the railway companies themselves, troubles from this source are not nearly so numerous as formerly, yet there are cases where installation is done by manufacturing companies, car builders and outside contractors, which would never pass inspection were the wiring done in any building of our larger cities. While the necessities for good work in this particular are of course far more apparent on a car body that is subjected to all sorts of movements and motions than in connection with the wiring of a building, the need of preparing for the last class of wiring was apparent years ago, and has been strictly followed ever since, so no argument is needed for the fixing of standard car wiring rules.

On standardizing switches, circuit breakers, bus bars, etc., I can offer no better argument than to state that your engineers well know the carrying capacity of certain weights of copper on their line of work and on the articles which I have mentioned the results should be as well known and established as any other feature in the transmission of current.

In conclusion, a word should be said on the important feature of protection against lightning. No detail of electric railway equipment costs so little, upon which so much is dependent as upon its lightning arresters. Defects in this particular may cause many thousands of dollars damage within an instant, so this question cannot be too carefully scanned and considered by your associations, and some standard fixed upon which will effectually protect your machinery.

On every feature of the business, the manufacturers will gladly conform to your actions and requests; and to sum up the whole situation in a nut shell, they exist for your benefit, not you for theirs, and that they now look to you for suggestions instead of making them to you.

[1] Read before the N. Y. State Street Railway Association, Binghamton, September 8, 1896.—Abstract.

ELECTRICAL DEVELOPMENTS ON THE B. & O.

In about thirty days the passenger trains of the Baltimore and Ohio will be hauled through the Belt tunnel by electricity. The extension now in progress of the overhead work to allow the electric locomotives to couple with passenger trains after they back out of Camden station, will be finished in that time. Another extension at the north end of the tunnel will enable the electric locomotive to haul trains to the vicinity of St. Paul street extended. This will dispense with the use of a helping engine.

At present two steam locomotives are used to haul trains, owing to the grade, and complaint is made by residents in the northern section of the smoke. In about two months this trouble will be abated.

An improvement is being made at the power station in the installation of a large coal handling plant. The plans provide for dumping the coal from cars into a hopper outside of the building and underneath the railroad tracks. From this hopper the coal is to be passed through a crusher and carried by means of buckets traveling on an endless chain to a large storage bin. Pipes lead from this bin to the doors of the furnaces, and the coal will require no manual handling from the time it leaves the mine until it is shoveled into the fires under the boilers.

A contract has been awarded to the Maryland Manufacturing and Construction Company for the installation of a fifth power generator unit to supply reserve power in case of emergency. This plant will include an 800 horse-power Greene tandem compound engine, directly connected to a multipolar 500 kilowatt railway generator. The installation will be in charge of Chief Engineer Hull, of the Construction Company's electrical department.

The B. & O.'s complement of electric locomotives is to be increased also in another way. A contract has been awarded to the General Electric Company for a small electric locomo-

tive. This is to be used in switching freight cars on Aliceanna and Wolfe streets, and will supersede the string teams of horses now used.

A trolley wire similar to those used by the street railway companies will be employed for this service. It is proposed by the company to use electricity wherever practicable, and it is expected that freight cars now handled along Pratt street by a dummy engine will eventually be hauled by electricity.

REPORT ON RAILS FOR STREET RAILROADS.[1]

BY C. LOOMIS ALLEN.

WE are careful to purchase ties of certain kind, quality and size; spikes of a particular type and size, and to have joints of such a length, thickness and weight; the rails to be of a certain section, weight and height are specified, but as to the character and quality of the metal to be used in the rails and their appurtenances nothing generally is said. In other words, we buy our rails taking what the rail makers give us so far as quality of material is concerned. I do not condemn the railmakers or believe that there is any intention on their part to give railroad companies any material other than that which will be of good quality and finish; but when the wear of traffic shows that there are certain defects in the rail, we naturally seek the cause and if possible the remedy. Some of our nine-inch rails after a traffic of two years, have shown such signs of wear considering the length of time they have been laid, that after investigation we have concluded that rails of a harder quality of steel would not have shown the wear of traffic to such an extent.

Rails of hard steel, the analysis of which showed a greater percentage of carbon than the standard specification of rail steel have been advocated by some of the steam railroad systems for some years, and I might add that their use has been a success in every way. The most notable instance of high carbon rails is that of the New York Central Railroad, upon the Hudson River division, near Spuyten Duyvil. These rails have been subject to as heavy traffic as any rails laid on this Continent. They have been under traffic for nearly six years, and up to this time, I believe, none have broken. When these rails were first delivered by the makers, so certain were they that the rails would become broken under traffic, that due warning was given the railroad company by the makers that they would not be responsible for the damage which would most certainly occur from breakage. It was my good fortune early this year to consult with one of the firms of inspectors of steel in regard to the wearing quality of high carbon rails as compared with that of rails known as standard Bessemer rail steel, and their judgment was that high carbon rails will give from 40 to 60 per cent. greater life than rails of standard Bessemer steel.

When steam roads began to ask for steel rails, the composition of which called for high carbon, an extra price from $2 to $4 per ton was asked by the railmakers, but to-day these rails are obtainable for the same price as those of standard rail steel specifications. In Syracuse this year we are laying rails 60 feet in length, 9 inches in height, and the half groove section. Our joint is the ribbed or corrugated twelve bolt, thirty-six inch joint. Our contract with the railmakers calls for rails the composition of which is as follows:

Carbon from 53 to 63; phosphorus, not to exceed .095; sulphur, not to exceed .07; Manganese, 80 to 1.00; silicon, .10 to .12.

We have had five miles of track of this specification, and in hopes to lay this year twenty miles, and we are expecting great results from these rails. I have noticed that the wear on the head of the rail by car wheels in the course of a month does not make any impression other than brightening the head of the rail; while in rails of standard specification I have seen the traffic of two weeks roll the metal in the head of the rail to the outside of the head to a very perceptible degree. The fact that there is a longer life to rails of hard steel will appeal to every railroad man as an economy which cannot be sacrificed.

THE POPE ELECTRIC VEHICLE.

There has been much interest in the expected appearance of the electric carriage made at the Pope bicycle factory, in Hartford, Conn. One evening the past week it appeared upon the streets of that city and was examined with great interest. The Hartford "Post" in speaking of it the next morning said: "The carriage is of a graceful, low body phæton form, handsomely upholstered. The front whels are about 24 inches in diameter, and the driving wheels about 32 inches. The carriage is of a handsome design and presents a luxurious appearance. The wheels have large inflated rubber tires, their size making riding in the carriage exceptionally agreeable. The storage system of electricity is used and the battery is placed beneath the seat. The power is applied to the axle of the hind wheels, speed being developed by a system of cogs. The power is controlled by a lever and there is a tiller to direct the course of the vehicle by turning the front wheels from side to side. A very pretty effect is produced by the carriage at night, there being quite a large reflector in front of the dashboard and lamps on each side. The new Pope carriage has seats for two persons, and it gets over the ground very smoothly and does its work finely."

MEETING OF THE NEW YORK STATE STREET RAILWAY ASSOCIATION.

THE fourteenth annual meeting of the Street Railway Association of the State of New York was held at the Bennett House, Binghamton, N. Y., Tuesday, September 8, 1896.

President G. Tracy Rogers called the meeting to order at 10:30, and Secretary Frick called the roll, when it was found that the following gentlemen were in attendance: C. Loomis Allen, Syracuse; J. P. N. Clark, Binghamton; W. W. Cole, Elmira; H. S. Cooper, Schenectady; R. E. Danforth, Buffalo; P. C. Deming, Buffalo; H. C. Evans, Brooklyn; Benj. Frick, Whitestone; Frank Gould, Oneonta; William E. Haven, Fishkill; J. M. Johnson, Binghamton; F. M. Hallock, Elmira; H. H. Hallock, Elmira; J. B. Lamfield, Binghamton; F. J. Maloney, Elmira; John H. Moffitt, Syracuse; F. P. Mooney, Cortlandt; Ira McCormack, Brooklyn; R. T. McKeever, Gloversville; Edmund O'Connor, Binghamton; George T. Rehn, Hornellsville; H. A. Robinson, New York; G. Tracy Rogers, Binghamton; John B. Rogers, Binghamton; C. L. Rossiter, Brooklyn; F. O. Rusling, Rochester; E. F. Seixas, Amsterdam; George H. Sliney, Brooklyn; J. H. Stedman, Rochester; C. B. Story, Hoosic Falls; Amos Van Etten, Kingston; Timothy S. Williams, Brooklyn; James I. Younglove, Johnstown.

President Rogers then read his opening address:[1]

The report of the Executive Committee was then presented, from which the following is taken: "Never before in the history of the association has there been such a large number of measures introduced in both branches of the Legislature in a single year, pertaining to the organization, operation and maintenance of street railroads. There were introduced during the last session of the Legislature, eighty-seven Assembly and fifty-three Senate bills, making a total of one hundred and forty bills and amendments directly affecting street railroad interests. The majority of bills introduced the past year were important in character, and would, had they become laws, have seriously affected the physical and financial operation of street railroads throughout the State.. We most heartily approve of the zeal, fidelity and persistency displayed by the officers, counsel and members of this association in advancing and protecting mutual business interests throughout the year."

The report of the treasurer showed the following financial transactions during the year: Receipts, $6,997.86; expenses, $6,700.88; balance, $296.98.

The reading of reports was then taken up, the first being by Mr. J. H. Stedman, of Rochester, "The Matter of Transfers." In part the report read as follows.

"One of the most important things to do and to do promptly, is to educate the average man and woman to ride. That this is largely a matter of education every street railroad manager knows. A liberal transfer system, properly guarded to prevent fraud, pays. This is, I think, now generally recognized. Local conditions and arrangements of lines must be considered in determining the regulations to be adopted. The rules intended to safeguard the company are important. Perhaps equally important is the making of rules broad enough to encourage riding.

"A large road in Baltimore three years ago employed me to arrange a transfer system. They yielded to my advice for more. extent of four transfer points, but I argued in vain for more. One year after, the manager again sent for me and said, 'When you urged me a year ago to increase my transfer privileges I thought you were a fool, and I am now convinced by a year's experience that the fool was another party.' The expediency of a liberal transfer system is beyond argument; it is an established fact; it does increase cash receipts. The more liberal, the more advantageous.

"Whether it is better to ring up transfers is a subject which has provoked much discussion. To ring them up does, of course, give them at once a cash value; but not to ring them paralyzes the spotter or detective, and the latter, I think, is generally admitted to be of greater importance. The weight of opinion seems now to be to ring up transfers, and preferably on a separate register. Nothing is absolutely a safeguard

[1] See page 283.

except the transfer method itself. With a protective transfer guarded by the coincidence of time and consecutive number in sequence of issue, honesty may be secured."

President Rogers stated that they had adopted transfers on their road, with a great deal of benefit to themselves and also to the public.

Mr. Rossiter inquired as to whether bicycles are seriously hurting the revenues of roads; and also how one can ascertain whether the transfers increase cash receipts. They were all in the habit of making comparisons with the corresponding month a year ago. Of course, the conditions are not the same in any of the larger cities. They gave a good many transfers and had made a very good showing. They might have made doubly as good a showing if they had not given any transfers. They carried 2,600,000 passengers on free transfers last month, and increased their earnings about $40,000. The other roads in the city which publish their reports monthly report a decrease, but there were a number of reasons why they should increase. They give a transfer to a passenger who is riding on a transfer.

Mr. Deming stated that in Buffalo there were a number of lines where it was necessary to give a second transfer, and in some cases a third. He found more trouble with passengers on a pleasant Sunday afternoon when they are riding around for pleasure than any other time. The system is laid out in such shape that it is possible to ride all day long on a transfer (Laughter.) He had been studying a new form of transfer, which may put a stop to it. That is, the idea of having every street that they run by printed on each transfer. When a passenger gets on one line, and wishes to go to a certain part of the town, he must ask for a transfer to that street, and that transfer is good on any car connecting the two lines. The transfer will be taken up by the conductor, and another issued to the passenger punched for the same street, and the moment the street is reached the ride ceases.

Mr. Stedman inquired whether people would not be inclined to "play the limit," and go as far as they wanted to.

Mr. Deming thought not any more so than they did now.

President Rogers inquired whether any roads transferred from one company to another company?

Mr. Cole stated that that was done in Elmira, but only on special occasions, when there was some combined attraction at the park.

Mr. Robinson: A great deal of difficulty arises in New York from the use of transfer tickets. There are some lines on which persons can get five or six transfers, and continue riding all day, if desired. We also have difficulty at the points where we have transfer agents and the tickets are punched. The passengers give the tickets to boys and the boys sell them, or they put them in places where other people can get them. Some investigations have been made to see whether people use tickets illegitimately, and although no record is kept of it, it is found from general observation that the abuse is not great. There are not many transfers to one person of more than three in number; such cases are few and far between. We consider that on some lines transfers have been of great benefit in increasing cash earnings, particularly in the retail dry goods district.

President: I think the general adoption of the transfer system is an indication that the street railroads are anxious to serve their patrons. There is no law compelling us to give the transfers, but the roads have done it, and they have found that in accommodating the public they have increased their revenues.

Mr. Moffitt stated that in Syracuse they carry about 25 per cent. of their passengers on transfers. Other members gave the following figures: Buffalo, about 32 per cent.; Binghamton, about 25 per cent.; Rochester, old system, 35 to 40 per cent.; new system, 27 to 30 per cent.; Brooklyn (Nassau Road), 20 to 25 in summer, 16 to 20 per cent. in winter; Brooklyn (Atlantic avenue Road), average 16 per cent.

The paper of C. Loomis Allen, of Syracuse, on "General Track Construction and the Most Approved Method," was then read.[1]

Mr. Rossiter stated that his road called for practically the same thing as in the paper, except the 30-foot lengths, but of high carbon. They were very satisfactory. They had had a few rails break in handling, but the results under wear were very much more satisfactory.

Mr. Evans stated that the Nassau Electric road (Brooklyn) used the regular Bessemer rail specification. The West End road, in Boston, used a little harder rail than any other road in the country. It was very seldom that the rail makers are asked for rails made up on any other than the regular Bessemer rail specification.

The next topic was the paper by Mr. W. W. Cole, of Elmira, "How can we prevent Accidents and Increase the General Efficiency of Employés."

[1] See page 281.

President Rogers called upon Mr. Robinson to explain the system of instruction in vogue on the Metropolitan street railway lines.

Mr. Robinson stated the Metropolitan Street Railway Company of New York organized a club, the chief object of which was to educate the motormen and conductors, and held meetings, to which all other operatives of the company were invited. The president opened up a room in one of the depots, and during the last season, ending the first of May, there were a series of lectures held every two or three weeks, illustrated with appropriate stereopticon views, and the subject of underground trolley, cable machinery, cable apparatus, in fact, the general operations of the road were made plain by means of the photographic views. He thought individual instruction preferable to that received at the lectures, but the lectures were entertaining, and they had been largely attended by the working classes. On the whole, they are considered very advantageous, and it is proposed to continue and, in fact, enlarge them during the coming winter.

President Rogers: Mr. Rossiter, do you not have a meeting once a week?

Mr. Rossiter stated they depended entirely on the instructors at the present time to turn the men over to the superintendents, competent to run the motors, and the superintendent is supposed to instruct them in regard to the details of each division, grade crossings, stops to be made at certain streets, etc.

Mr. Fitch, of the Erie, and Mr. Hammond, of the Delaware & Hudson Canal Company, gave the result of their experience in the same line.

A paper by Mr. H. S. Newton was then read, entitled. "Power from the Trolley Circuit, etc."

Mr. Cole stated that some of the small roads run so close to the entire output of their generators that if they supply the power consumers they can never figure on the power they are going to have on the line. Mr. Story thought it best to run power circuits from a separate dynamo.

The paper by Mr. James B. Cahoon, on the "Daily Inspection and Care of Car Equipments" was then read.

President Rogers called for remarks on this paper.

Mr. Cole thought that there were some objections to the motormen or conductors making any special inspection; it soiled the clothing in a short time, and the men would wear a poorer class of clothing. It was unpleasant for the passenger to have a conductor with dirty hands.

A paper was then read by Mr. H. S. Cooper, of Schenectady, on "The Desirability of Forming a Board of Claim Agents."

AFTERNOON SESSION.

The first business was the reading of a paper by Mr. F. O. Rusling, of Rochester, on "The Use of Old Rails as Underground Conductors."

There being no discussion on this paper, the meeting proceeded to consider the next paper, entitled "Railway Power Stations," by Mr. Thomas Henning, of Buffalo, N. Y.

Mr. W. J. Clark, of New York, upon invitation of the President, contributed a paper on the general subject of "Rating of Electric Railway Apparatus."[2]

Mr. H. A. Robinson then submitted some notes on the management of accident cases as practiced by the Metropolitan Street Railway Company.

The president stated that an invitation had been received from Mr. W. Caryl Ely, President of the Buffalo and Niagara Falls Railroad, to hold the next convention at Niagara Falls; also that an invitation had been received from Saratoga.

On motion of Mr. Clark, it was decided to hold the next meeting at Niagara Falls, and that two days be devoted to the meeting.

The following officers were then elected for the ensuing year: President, G. Tracy Rogers, Binghamton, N. Y.; 1st vice-president, W. Caryl Ely, Niagara Falls, N. Y.; 2d vice-president, John N. Beckley, Rochester, N. Y.; executive committee, H. H. Vreeland, New York; John W. McNamara, Albany; Henry M. Watson, Buffalo; C. L. Rossiter, Brooklyn; secretary and treasurer, H. A. Robinson, New York.

The meeting then adjourned to meet at Niagara Falls the first Tuesday in September, 1897, and the delegates started for a trolley ride to Ross Park, State Hospital, and other local points of interest, terminating with a ten-mile ride to Union.

A banquet was held in the evening.

PITTSBURG, PA.—Director J. C. Brown, of the Department of Public Safety, has let the following contracts: Gas and electric light plant for the new public safety building on Sixth avenue, to J. L. McShane & Co., $3,000; disinfectant plant, to the Kensington Engine Company, Limited, of Philadelphia, for $3,099; storage battery system was captured by the Gamewell Fire Alarm Company, for $4,270.

[2] See page 280.

THE CONDITIONS OF THE STREET RAILWAY INDUSTRY.[1]

BY G. T. ROGERS.

The past year has not been marked by any startling or radical changes in the street railway world. The same tendency toward better building seems to prevail. The extension of roads into the country, the construction and adoption of high speed motors and larger cars and the rolling and laying of sixty-foot rails have all been tried successfully. The exercise of greater care in providing for the return current is to be observed, but perhaps the most important advance is in the universal adoption by large plants of the direct connected generators; indeed I am informed that over eighty per cent. of the generators produced during the past year are of this character.

However, it still remains a question whether the adoption of direct connected units is true economy in smaller cities and towns where the total demand for power is not great, real estate comparatively cheap and the load variable, necessitating the use of several small units. The relative cost is greater than where the sizes are larger. The advantage of connecting several small units to shafting to avoid an entire shut-down is also to be considered. In short, each type of generator is adapted to certain conditions to be met.

The experience of the past year has demonstrated that where very long lines of street railways are to be operated, power can be economically delivered twenty miles or more from the power station by the three-phase system and the use of high tension current. The experience of the past year has also demonstrated that with direct current machines longer lines than we had previously supposed, can, by the addition of boosters, be operated economically. Some fifteen or twenty different roads in the United States are now using this system. All of these improvements are enlarging our field of business and opening the sole available field of connecting suburban towns.

The new subway in Boston is rapidly approaching completion. It is unique in many respects. The cars on the overhead trolley system will leave the surface and by a rapidly descending grade enter a double track subway with underground stations at intervals. The subway will relieve the streets in the congested sections of the city very considerably. A unique feature of the system will be the terminal arrangements at points where the different routes end. Instead of returning upon the same tracks, the car will continue forward past an "island" station and by the former level and the opposite track. High speed can be maintained in sections of the city where it would otherwise be impossible.

A number of interurban and suburban trolley roads have been completed and operated during the past year with almost phenomenal success. A well built road of this character, starting from a fair sized city, and owned and operated by the city company and tributary to its system, connecting one or more thrifty villages with the city, to my mind, will pay. Such has been our experience with the Binghamton, Lestershire and Union Railroad. In this case we own most the right of way, obtained where necessary by proceedings under the laws as amended in 1895. We generally found the farmer along the route welcomed the trolley road since it served him personally, which a steam road would not, and he was very reasonable in his demands.

Never in the history of this association have there been so many questions of vital importance confronting us. I will call your attention to a few and I trust that in case some of you do not agree with me in my views, you will pardon my alluding to the present political situation. In my opinion it is bad policy for the railroads to enter the political field, but we should, as far as possible, see that good, clean men are elected to make the laws under which we act. The street railways of this country can take but one position on the money question which is now forced upon us. Our bonds, both principal and interest, are almost uniformly payable in gold, and should this country adopt the silver basis, we must pay gold and accept the depreciated currency of the country for our fares which are fixed and cannot be advanced. We cannot place the situation before our employés any too forcibly or plainly, as they will be the greatest sufferers. The situation is a grave one for all railroad interests and demands our careful consideration.

From the Railroad Commissioner's report of 1895, I find that it has cost all roads of the State 91½ per cent. of their gross receipts for operating expenses, interest, taxes and rentals. Ninety-one and one-half per cent. of the five-cent fare we receive is four cents, five and three-quarter mills, leaving but four and one-quarter mills profit for dividends. In New York City one legitimately rides twelve and one-half miles for five cents, transportation .004 per mile; in Brooklyn eighteen miles, transportation .0028 per mile, and in Buffalo thirteen and three-quarter miles, transportation .0037 per mile. The street railway in the State of New York to-day affords the cheapest transportation in the world.

The question of fenders is still confronting us and is a most perplexing problem. More patents for street car fenders have been granted during the past few years than for any other class of inventions. It is stated upon good autherity that there are upwards of four thousand on the market, and I dare not estimate the number left in the brain of would-be inventors. It is the opinion of many street railway men that the fender is a menace.

Your Executive Committee were anxious that an act be passed regarding fenerds. There were a number introduced. The one introduced by the chairman of the Assembly Railroad Committee seemed to meet the approval of the public and was heartily endorsed by your Executive Committee, but for some reason it never became a law. The street railways are anxious that the State should share some of the responsibility. I stated last year, and still believe, that the best fender for the front end of a car is a clear headed motorman.

The pleasant relations now existing between the steam railroad and street railway companies of this State are a subject of congratulation, although in many instances the interests are conflicting. In many States it is almost a case of the Kilkenny cats. It is a pleasure to be able to state that the existing situation in New York has been largely brought about by the Executive Committee of your association. A proposition to consolidate the two organizations in one association is now under consideration.

[1] Abstract of Presidential Address before N. Y. State Railway Association, September 9, 1896.

MOTORCYCLE RACES AT PROVIDENCE, R. I.

An interesting series of motorcycle races came off last week at Providence, in Narragansett Park, under the auspices of the Rhode Island State Fair Association. Prizes of several thousand dollars in the aggregate were offered, and the main idea was that if weather permitted, five races, each of five miles, should take place, or one daily. The following were the entries: Duryea Motor Wagon Company, Springfield, Mass.; Morris & Salom, Philadelphia, Pa.; W. Lee Couch, New Brighton, Pa.; Lewis Brown, Sawkill, N. Y.; P. F. Olds & Son, Lansing, Mich.; Riker Electric Motor Company, Brooklyn, N. Y.; J. Frank Duryea, Springfield, Mass.; Geo. H. Morrill, Jr., Norwood, Mass.; Geo. H. Hewitt, Springfield, Mass.; Fiske, Waren & Co., Boston, Mass.; Wm. M. Ashley & Son, Springfield, Mass.; C. Mayhew & Son, Saratoga Springs, N. Y.; The Morris & Salom and Riker electric carriages, already described in these pages, were the only electric vehicles entered. Nearly all, if not all of the others, were of the gasoline motor type.

Owing to the severe storm which swept the New England coast during the week, with effects felt for two days, the plans for the race were thrown into disorganization and had to be modified in keeping with the horse, bicycle and other races, all of which were affected by the prevalence of the storm and the condition of the track. The motorcycle contestants were desirous of going on in spite of the weather, but as the management had an eye to the attendance and gate money, it declined. The result was that but three of the heats were run, two being won by the Riker carriage, while the Morris & Salom vehicle also made a better showing than the Duryea. The prize money offered had been corespondingly reduced, and but three-fifths of it will be paid.

The Riker motor won the first two heats;the Morris & Salom the third, with he Riker a few yards only behind. The fastest mile was made by the Riker motor in 2 minutes 13 seconds. The fastest five miles was that of the Morris & Salom in 11 minutes 27 seconds. The first prize to the Riker is $900; the second to the Morris & Salom is $450. The prizes would have been larger had all the heats been run.

LEGAL NOTES.

TROLLEY BASE LITIGATION.—THE SIMONDS MFG. CO.

The United States Circuit Court for the District of Western Pennsylvania has modified the injunction obtained against the Simonds Manufacturing Company by the Thomson-Houston Electric Company, permitting the former now to sell trolley parts of all kinds, and the trolley base under the Duncan patent.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Alternating Current:

WATTLESS CURRENTS IN POWER DISTRIBUTION BY MEANS OF ALTERNATING CURRENTS.—By André Blondel. Paper read before the International Congress of Electricians at Geneva. The magnetizing wattless current, which lags 90 degrees, forms the subject of the paper. In the discussion the terminology of the word was subjected to lively debate, Palaz, Hospitalier, Ferraris, Mascart and others taking part.—Lond. "Engineering," "Elec Rev.," Sept. 9, '96.

Dynamos and Motors:

CONTINUOUS CURRENT GENERATOR FOR THREE-WIRE SYSTEM.—By A. Rothert. The three-wire system for electric lighting would be more popular still than it is, if it did not require two small dynamos instead of one large machine. The neutral wire could be joined to a third brush placed midway between the two others; such brushes are right in the field, however, and spark badly. Generators with two independent windings on the armature and two collectors in series had answered under certain circumstances. Dobrowolsky has connected two fixed points on the armature of maximum potential difference by a choking coil, and has started the neutral wire from the middle of this coil.—Lond. "Engineering," "Elec. Rev.," Sept. 9, '96.

Measurements:

METRIC SYSTEM.—Test of Government bill brought by the president of the Board of Trade to legalize the use of weights and measures of the metric system.—Lond. "Practical Eng'r," Aug. 14, '96.

Mechanical:

DOUBLE CROSSLEY GAS ENGINE AND DIRECT DRIVEN DYNAMO.—Illustration of a 60 nominal horse-power gas engine running at 160 revolutions per minute and direct coupled to a Siemens & Halske dynamo.—"Sc. Am. Supplem.," Sept. 5, '96.

RUNNING EXPENSES OF GAS VS. ELECTRIC MOTORS.—Detailed experimenting disclosed that the expenses for the gas motor running free were 56 per cent. of the motor running at full load, while the electric motor running free showed an expense of 13 per cent. of the same, running full load. When running under full load, however, the gas motor is 26 per cent. cheaper than the electro motor.—From "Uhland's Verkehrszeitung" and "Génie Civil," in "Elektrotechn. Anzeiger," Aug. 30, '96.

Power Transmission:

HIGH TENSION CONTINUOUS CURRENT DISTRIBUTION.—By René Thury. Paper read before the International Congress of Electricians at Geneva. The system has been adopted in Biberist, Brescia, Geneva, Genoa, etc. The Biberist line has a length of 15 miles; in Brescia 700 horse-power are transmitted over a distance of 12 miles; up to 15,000 volts are employed. Thury claims that his lines are easily calculated and his switchboards simple; that the regulation of the speed of the motors answers well; the motors can easily be started; that the consumers can not use more current than they are entitled to; that the lightning trouble, which is very serious in many parts of Switzerland, has successfully been overcome, and that the high tension involves no danger. His machines stand on porcelain insulators, imbedded in cement or beton; the floors are asphalted.—Lond. "Engineering," "Elec. Rev.," Sept. 9, '96

LONG DISTANCE POWER TRANSMISSION.—By Charles S. Bradley. Paper presented to the International Congress of Electricians at Geneva. The paper consisted of two sections: (1) Author advocates monophase transmission down to his transformers and polyphase motors. (2) He discussed his ideas on phasing transformers. In abstract only in Lond. "Engineering," "Elec. Rev.," Sept. 9, '96.

Roentgen Rays:

A LECTURE ON THE RECENT ROENTGEN DISCOVERY.—By Fred S. Kolle, M. D., Brooklyn.

This lecture is one of twelve delivered in Brooklyn, and consists of a résumé of the work done up to date. Dr. Kolle was one of the first medical men to take up the subject, and he has devoted his thoughts and energies to it systematically. He advances some useful ideas and suggestions. (Pamphlet.)

WAVE LENGTH OF ROENTGEN RAYS.—Dr. Fromm found the wave length about fifteen times smaller than the smallest hitherto observed in ultra violet. Further details are taken from "Nature" in "Elec. Eng'r," Sept. 2, '96.

Thermo-Electricity:

COX THERMO-ELECTRIC GENERATOR.—The various improvements which have been made principally in consequence of welding the various elements together. Also a description of Mr. Cox's laboratory in England.—Lond. "Elec. Rev.," "Elec. Rev.," Sept. 9, '96, "Elec. Eng'r," Sept. 9, '96.

Telephony, Telegraphy, etc:

CABLE LAYING GEAR ON THE STEAMSHIP "TUTAUEKAI."—An illustrated description in "Elec. Rev.," Sept. 9, '96.

Wiring:

AUTOMATIC DISCONNECTION OF BROKEN WIRE FROM CIRCUIT.—Gould & Company patent specification. An illustration and description of a peculiar coupling, by means of which an entire section of wire is thrown to the ground in the case of breaking at any point, thus preventing a hanging wire.—"Elektrot. Anzeiger," Aug. 30, '96.

NEWS AND NOTES.

A NEW YORK GAS EXHIBITION.

THE plans for a gas exhibition in this city appear to be now in good shape, and the preliminary announcements are made in the "Progressive Age," of this city, whose well known editor, Mr. E. C. Brown, appears to have affairs in charge. The place is to be Madison Square Garden, and the time will, in all probability, be two weeks in January, 1897. This does not leave too much leisure for preparation, but as the Garden is always ready and as the exhibits do not take long to fit up, it should prove ample. About 20,000 square feet of space will be provided for exhibits, and of this, over 5,000 square feet had been taken up before public announcement. In size, therefore, the Gas Exhibition will by no means approach the recent Electrical Show, nor can it possibly compare with it in the variety of industries illustrated or affected, but it should prove very interesting and attractive. Gas is still a mighty agent for illuminating purposes, and there should be many exhibits of that nature, while the season of the year will offset the heat likely to be generated by a large consumption of gas. But there are other things of importance and worthy of inclusion, and we trust that the whole gas art will be demonstrated in an instructive manner. It is greatly to be hoped that there will be a good and comprehensive exhibit of gas engines. We think such things should also be included as thermo-generators, giving the public an opportunity to see a gas jet furnishing electrical energy enough to run a fan motor, a light, and half a dozen other pieces of apparatus. In fact, many central station men are to-day actively interested in the use of fuel and illuminating gases, and the exhibition may be considered as no less useful to all electric lighting engineers and managers, and should be no less an incentive to them than to those who are specifically devoted to the manufacture and distribution of gas.

REPORTS OF COMPANIES.

WESTERN UNION.

The Western Union Telegraph Company have declared a quarterly dividend of 1¼ per cent. The following is a statement of business as compared with actual figures in 1895: Net revenues of $1,600,000, a decrease of $242,648; interest and sinking funds, $243,500, a decrease of $57; balance $1,356,500, a decrease of $242, 591; dividends, $1.191,960, an increase of $15; surplus, $164,540; a decrease of $242,606; previous surplus, $7,643,693, an increase of $196,217; total surplus, $7,808,-233, a decrease of $46,389.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED SEPT. 8, 1896.

Alarms and Signals:—

CONTACT DEVICE FOR ELECTRIC BURGLAR ALARMS. P. Unger, Lemont, Ill., 567,176. Filed June 22, 1896.
Details of construction.

ELECTRICAL TRAIN SIGNALING DEVICE. J. E. Young and E. S. Norton, Conneaut, O., 567,211. Filed May 11, 1896.
Means for sounding an alarm in the engine cab when an accident has happened to the train.

Distribution:—

ELECTRICAL TRANSFORMER. H. M. Hobart, Boston, Mass., 567,237. Filed May 15, 1896.
A built up core having its sides and ends composed of bundles of laminæ of magnetizable material united at their ends.

ELECTRICAL TRANSFORMER. W. S. Moody, Lynn, Mass., 567,250. Filed March 30, 1896.
Details of core construction.

TRANSFORMER FOR ELECTRIC CURRENTS. R. Thury, Geneva, Switzerland, 567,424. Filed Feb. 3, 1896.
Details of construction.

Dynamos and Motors:—

CONSTANT POTENTIAL ALTERNATING GENERATOR. E. W. Rice, Jr., Schenectady, N. Y., 567,197. Filed May 15, 1896.
In combination, an alternating current dynamo electric machine, a transformer having a primary coil in shunt to the mains, a secondary, and a modifying magnetic shunt, and a rotary converter connected upon its alternating current side to the transformer secondary, and upon its other side to the field magnets of the alternator.

DYNAMO ELECTRIC MACHINE. R. Thury, Geneva, Switzerland, 567,423. Filed Aug. 5, 1895.
The combination with the magnetic poles, of a series of laminated rings and a continuous surface of wire in groups wound in opposite directions, so that the alternating magnetic actions set up currents throughout the coils.

Electro-Metallurgy:—

MAGNETIC SEPARATOR. R. Eickemeyer, deceased; R. Eickemeyer, Jr., executor, Yonkers, N. Y., 567,381. Filed Jan. 10, 1890.
A rotative drum provided with longitudinal separating bars of iron, and an interior stationary electromagnet, having a series of ribs, segmental in form and each inclosed longitudinally by its own field coil.

MAGNETIC SEPARATOR. R. Eickemeyer, deceased; R. Eickemeyer, Jr., executor, Yonkers, N. Y., 567,382. Filed Jan. 28, 1890.
Similar to above.

PROCESS OF EXTRACTING GOLD AND SILVER FROM THEIR ORES. L. Pelatan, Paris, France, and F. Clerici, Milan, Italy, 567,503. Filed Jan. 10, 1896.
Consists in submitting the ores of gold and silver to the action of a comparatively weak cyanid solution containing chlorid of sodium and treating them electrolytically.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. E. F. G. H. Faure and J. MacHaffie, New York, 567,227. Filed March 20, 1896.
Details of a focusing arc lamp.

SAFETY DEVICE FOR HANGING ELECTRIC ARC LAMPS. E. P. Snowden, St. Joseph, Mo., 567,322. Filed Jan. 23, 1896.
Means by which the current is shifted from the lamp direct through the springs when the lamp is lowered.

ELECTRIC SIGNAL LAMP. J. R. Farmer, St. Louis, Mo., 567,338. Filed March 14, 1895.
A lamp that revolves automatically on the approach of a car.

ARC LAMP CLUTCH. H. R. Palmer, Norfolk, Va., 567,355. Filed June 10, 1896.

HOLDER FOR ELECTRIC LAMPS. W. S. Arnold, San Francisco, Cal., 567,531. Filed March 17, 1896.
Details of construction.

Miscellaneous:—

ELECTRIC LOCK. W. S. Nash, Knoxville, Tenn., 567,156. Filed Nov. 21, 1895.
Details of construction.

ELECTRIC HEATER. J. E. Meek, New York, 567,247. Filed Jan. 7, 1896.
Consists of a woven fabric of asbestos, with an electric conductor embedded in the woof of said fabric, and a backing of incombustible mill board.

ELECTRIC HEATER. J. E. Meek, New York, 567,248. Filed Jan. 7, 1896.
Similar to above.

GALVANIC RING. M. L. Thompson, Brooklyn, N. Y., 567,422. Filed June 29, 1896.
Invented for medical purposes.

ADVERTISING DEVICE. F. A. Ruge, Springfield, N. Y., 567,514. Filed May 22, 1896.
Means for closing the circuits through any desired series of lamps and leaving the others cut out.

SWING FOR ELECTRIC LIGHT OR TELEPHONE BRACKETS. A. Petereit, New York, 567,550. Filed Nov. 15, 1895.
A joint consisting of a slotted hollow main section or socket; in combination with a removable section adapted to be supported in the first section.

ELECTRIC TYPESETTING MACHINE. Joseph Sachs, New York, N. Y., 567,256. Filed Dec. 24, 1894.
Details of construction.

Railways and Appliances:—

TROLLEY WIRE CROSSING. H. M. Handsby, San Antonio, Tex., 567,133. Filed March 19, 1896.
Details of construction.

TROLLEY WIRE AND TROLLEY WHEEL. P. Cassidy, Worcester, Mass., 567,186. Filed May 8, 1896.
A trolley wire comprising a substantially cylindrical rib and a tapering V-shaped body portion for engaging the trolley wheel, and a wheel having a V-shaped groove for engaging the wire.

ELECTRIC RAIL BOND. G. H. Scott, Worcester, Mass., 567,257. Filed March 9, 1896.
Consists of a connecting rod or wire, and two collars, one for each end of said rod or wire, adapted to fit over the ends thereof, and an opening in the rails.

ELECTRIC RAILWAY TROLLEY. R. N. Dyer, East Orange, N. J., 567,306. Filed April 30, 1896.
An upward pressure trolley, a solenoid and core for moving the trolley upwardly and a multiplying gear connecting the solenoid core with the trolley.

ELECTRIC RAILWAY TROLLEY. R. N. Dyer, East Orange, N. J., 567,307. Filed April 30, 1896.
Similar to above.

TROLLEY. E. D. Preist, Schenectady, N. Y., 567,411. Filed May 13, 1896.
The combination of an overhead conductor, a contact device supported thereby, arms extending between the contact device and the vehicle, and a piece pivotally secured to the contact device and the arms, permitting movement between them.

INSULATED RAIL JOINT. R. C. Scofield, Boonton, and J. Wayland, Newark, N. J., 567,416. Filed July 22, 1896.
Comprises insulating coupling blocks at the sides of the rails and a bedplate for the rail ends having an upwardly extending rib on one side only.

TROLLEY FOR ELECTRIC CARS. J. E. Hewes, Philadelphia, Pa., 567,474. Filed May 7, 1896.
Means for lowering the free end of trolley on leaving wire.

CAR STORAGE ARRANGEMENT. E. F. Mann, Detroit, Mich., 567,487. Filed Nov. 20, 1895.
Comprises a track and trolley wire extending above the track, a break in the trolley wire near the entrance to building, and a switch located outside of building adapted to throw the trolley wire in and out of circuit.

ELECTRIC RAILROAD. O. Sill, New York, 567,517. Filed Nov. 1, 1895.
Comprises switches provided with insulation, consisting of tubes and alternate layers of cement, arranged one within the other.

ELECTRIC RAILWAY. W. F. Grassler, Williamsport, Pa., 567,540. Filed May 8, 1896.
A third-rail system.

MOTOR MOUNTING AND DRIVING MECHANISM. Ernest J. Bagnall, Cleveland, O., 567,560. Filed Sept. 4, 1895.
Permits of vertical motion only.

Regulation:

RHEOSTAT. W. W. Dean, St. Louis, Mo., 567,223. Filed March 28, 1896.
The combination, with a non-combustible core, of a resistance wire, a non-combustible, flexible envelope, metal clips, base and springs.

GOVERNOR FOR REGULATING SPEED OF MACHINERY. E. Thunderbolt, Carlton, Victoria, 567,366. Filed July 10, 1896.
The combination of an electromagnet adjustably secured to a lever having a spring attached thereto at one end and at the other end to a slotted frame in combination with a pin centered upon an adjustable plate and a vertical rod adjustably connected with the lever.

Switches, Cut-Outs, Etc:

AUTOMATIC CIRCUIT BREAKER. E. M. Hewlett, Schenectady, N. Y., 567,137. Filed April 17, 1896.
One magnetic device breaks the circuit at a predetermined overload and at the same time blows out the arc caused thereby.

Telegraphs:

TELAUTOGRAPH. G. S. Tiffany, Highland Park, Ill., 567,325. Filed June 7, 1895.
Means for charging the batteries of the various instruments of the system from a central station.

Telephones:—

TELEPHONE TRANSMITTER. R. P. Green, Columbus, O., 567,132. Filed May 31, 1895.
Embodies a secondary diaphragm and granular conducting material.

TELEPHONE SWITCH. D. Rousseau, New York, 567,170. Filed March 18, 1895.
A switch for enabling communication to be established by the subscriber with a number of telephone stations.

TELEPHONE TRANSMITTER. A. Stromberg and A. Carlson, Chicago, Ill., 567,324. Filed Oct. 29, 1895.
Employs granular carbon

APPARATUS FOR TELEPHONE SWITCHBOARDS. F. R. McBerty, Downer's Grove, Ill., 567,404. Filed Jan. 24, 1896.
Call distributing system.

SOCIETY AND CLUB NOTES.

Y. M. C. A. ILLUSTRATED LECTURE ON ROENTGEN RAYS.

On Friday evening Sept. 25 a lecture will be given in Association Hall, Fourth avenue and Twenty-third street, by Mr. Max Osterberg, E. E., A. M., on "The Possibilities and Limitations of the Röntgen Rays." Mr. Osterberg is the instructor in the evening class in electrical engineering at the Twenty-third street branch of the Y. M. C. A., and has kindly volunteered his services for this lecture.

The proceeds will be devoted to securing apparatus with which to illustrate the instruction in the class room. Besides exhibiting and explaining the Röntgen rays apparatus, Mr. Osterberg will illustrate his lecture throughout with a stereopticon lantern. Tickets may be secured at this office; price fifty cents.

THE OLD-TIME TELEGRAPHERS and the U. S. Military Telegraph Corps held their annual meeting at Pittsburgh last week, and enjoyed a very pleasant reunion. Mr. J. Compton, of Nashville, was elected president.

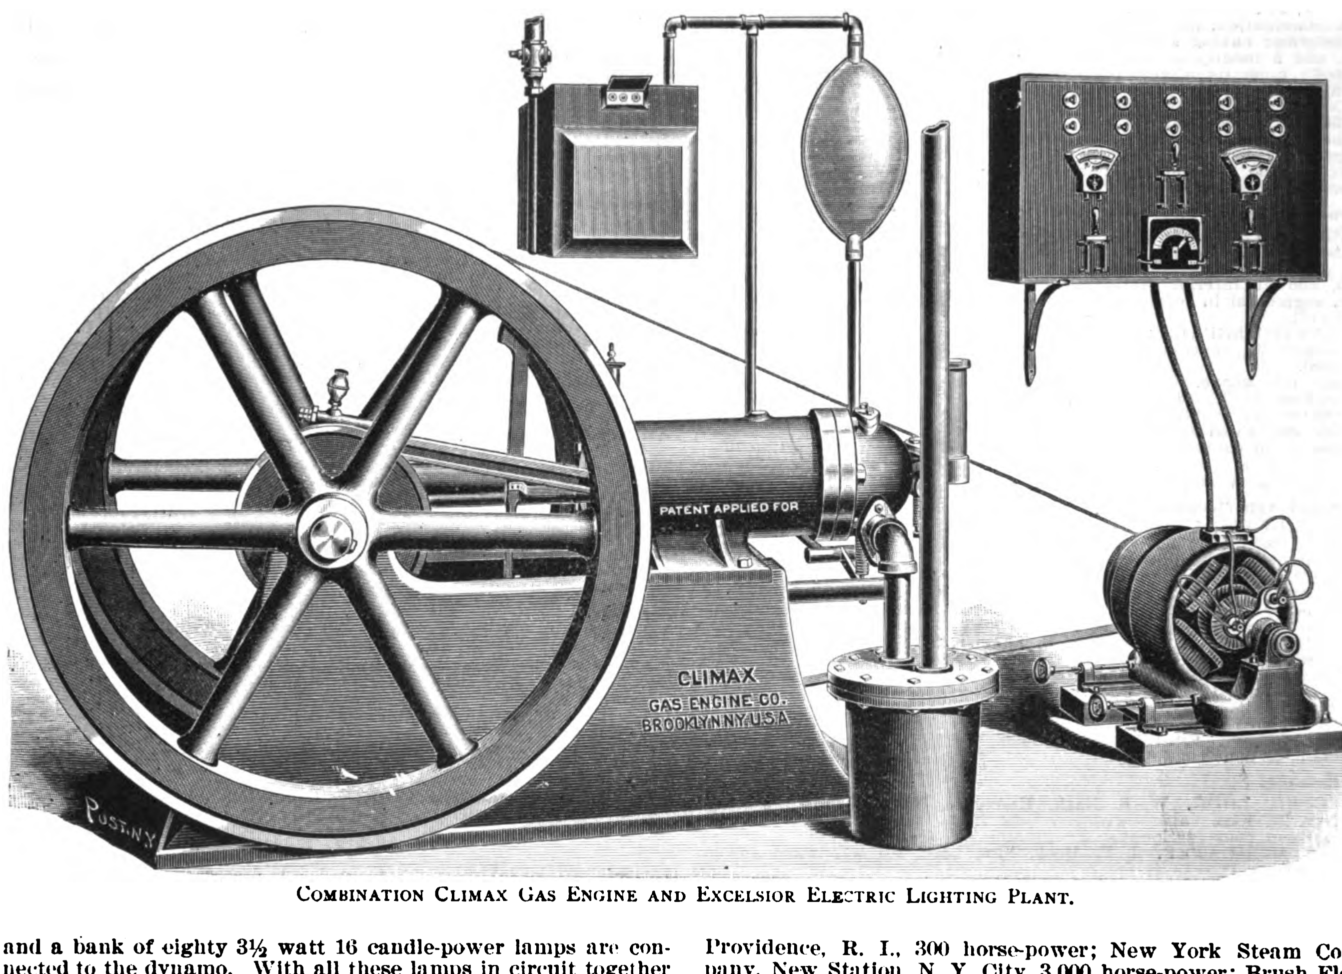
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE CLIMAX GAS ENGINE.

IT has often been pointed out that a given amount of candle power of illumination could be far more economically obtained from incandescent lamps by burning gas in a gas engine driving a dynamo than by burning gas direct in the ordinary burners. One of the most striking examples of this kind which has lately come under our notice is embodied in the gas engine on the premises of the Climax Gas Engine Company, at 31 Fulton street, Brooklyn, N. Y. This plant, which is illustrated in the accompanying engraving, consists of a Climax gas engine of 12.2 indicated horse-power, driving a dynamo of the Excelsior Electric Company of the Churchward 4-pole type by direct belt connection without countershaft. The dynamo has a capacity of 5.6 kilowatts, and operates at 110 volts at 1,250 revolutions per minute, the gas engine running at 260 revolutions.

In order to show the exact gas consumption of the engine, a meter is directly connected to the inlet valve on the engine, and a bank of eighty 3½ watt 16 candle-power lamps are connected to the dynamo. With all these lamps in circuit together with a pilot lamp, making eighty-one altogether, the gas consumption by actual measurement does not exceed 210 cubic feet per hour. It will thus be seen that assuming a five-foot burner and gas at 20 candle-power it would require no less than 325 cubic feet of gas to produce the same amount of illumination directly from gas burners.



COMBINATION CLIMAX GAS ENGINE AND EXCELSIOR ELECTRIC LIGHTING PLANT.

The engine is of the regular 4-cycle type giving an explosion at every other revolution, the crank shaft being provided with balance discs. The engine has a cylinder of 7 inches in diameter by 14 inches stroke. As the question of steadiness of running is an all-important one for engines operating incandescent lamps, the governing has been especially looked after, and the fluctuations in speed are claimed to be less than 2 per cent. The indicator cards of the engine show a very smooth curve, with a m. e. p. of 80 pounds to the square inch. The mechanical parts of the engine have been very carefully worked out and the company is now ready to deliver for immediate service three sizes of engines, namely, of 9, 13, and 35 horse-power. Larger engines for direct connection to generators for lighting, as well as for railroad service, are now in the course of preparation. The plant illustrated above can be seen daily in operation.

CLONBROCK STEAM BOILER CO.

The Clonbrock Steam Boiler Company of Brooklyn, report a large rush of business, their order sheets being so full that it is necessary to have on a night force to complete orders already booked for January 1, 1897. Among their latest orders are the American Manufacturing Company, Brooklyn, 500 horse-power; Hazelton Light Company, Hazelton, Pa., 800 horse-power; Peoples Light & Power Company, Jersey City, N. J., 800 horse-power; Municipal Electric Light Company, Brooklyn, N. Y., 2,000 horse-power and one steel self-supporting smoke stack, 16-inch diameter and 175 inches high; Economy, Light, Heat & Power Company, Scranton, Pa., 1,000 horse-power; Johnson Coal Company, Priceburg, Pa., 400 horse-power; Marshall Paper Company, Turners Falls, Mass., 150 horse-power; Peoples Light & Power Company, Orange, N. J., 200 horse-power; Geo. Watkinson Rubber Works, Philadelphia, Pa., 250 horse-power; Esperanza Plantation, Bayou Lapourche, La., 600 horse-power; Mathieson Alkali Works, Providence, R. I., 300 horse-power; Brush Electric Company, Providence, R. I., 300 horse-power; New York Steam Company, New Station, N. Y. City, 3,000 horse-power; Brush Electric Company, Baltimore, Md., 1,000 horse-power; Coney Island & Brooklyn R. R. Company, Brooklyn, N. Y., 700 horse-power.

EUGENE MUNSELL & CO'S. MICA.

Eugene Munsell & Company state that their mica business has been established more than 50 years, so that when there began to be a call for mica for electrical insulation, they had experience which enabled them to meet the demand, and that they have since been constantly enlarging their facilities, and studying to meet the varying and increasing requirements of the elctrical trade. They also state that their mica is received direct from the mines, and not through second hands.

Mr. Franklin Brooks, the junior member of the firm, has recently spent considerable time among the rich mines in Bengal, India, perfecting arrangements by which they receive the finest electrical mica in the world, selected and prepared according to their own instructions. They also have ex-

tensive relations with Canadian miners which enables them to furnish the best amber mica, where that quality is desired.

The electrical trade, as a rule, prefer to have their orders filled promptly, and this is one of the features of Eugene Munsell & Company's business of the past, that they guarantee almost immediate delivery of any orders placed with them. The company has recently established a branch house at Chicago to supply their Western customers.

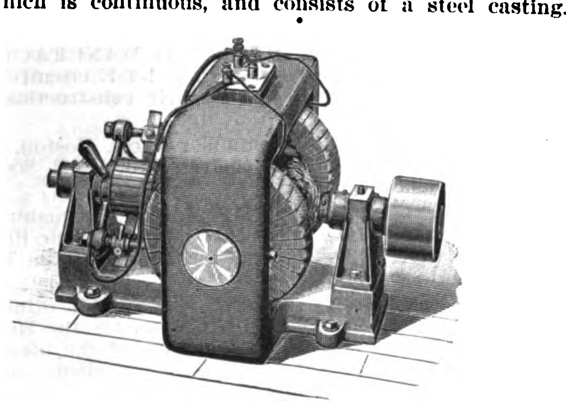
CENTRAL ELECTRIC X-RAY SHADES.

The great variety of uses to which the incandescent lamp has been put, in practical as well as purely decorative lines has taxed the ingenuity of designers to keep up with the demand for novelties. Probably in no direction has this demand been manifested more than in the line of glass, porcelain and metal shades. One of the prettiest and at the same time very useful forms recently put on the market is the X-ray shade. These are manufactured for the Central Electric Company, 173-175 Adams street, Chicago. The illustration gives but a faint idea of the brilliancy and beauty of the shade and is only one of a great number of designs carried in stock by them. They are greatly pleased with the reception given this shade by the general trade and have already sold several hundreds of them. Being plated with aluminum they can be washed with water without injury. They are suitable for all purposes where a shade is needed. It is claimed that they will greatly increase the efficiency of light. An inspection of the great stock of general electrical supplies carried by the Central Electric Company does not indicate that they are expecting any remarkable "slump" in the fall trade. On the contrary one would think they were looking for a grand revival of business, and we sincerely hope that no one will be disappointed.

THE RUPRECHT DYNAMO AND MOTOR.

OUR engraving illustrates the dynamo and motor just brought out by the Ruprecht Electric Company, of 236 Superior street, Cleveland, O.

Among the characteristics of this machine is its magnetic circuit which is continuous, and consists of a steel casting.



THE RUPRECHT DYNAMO AND MOTOR.

The field magnet-coils are wound separately and slipped over the cores which are let into the sides of the steel frame.

The commutator is divided into a large number of bars, thus reducing any tendency to spark. Forged steel shafts are employed in these motors together with phosphor bronze bearings. The center of gravity is very low and the speed as well so that these machines operate without perceptible noise or vibration. They are built in various sizes.

REPEAT ORDERS FOR McEWEN ENGINES.

It is obviously gratifying to manufacturers to receive a duplication of orders for their goods from people who, having tried them, are thoroughly familiar with their merits. The J. H. McEwen Manufacturing Company, Havemeyer Building, New York, may well be proud of the numerous repeat orders received from former patrons, the latest coming from the well known firm, Messrs. A. M. Rothschild & Company, of New York and Chicago.

Messrs. Rothschild & Company have had in operation for the past eighteen months two 100 kilowatt Thompson-Ryan generators direct connected to 15-inch by 16-inch McEwen automatic engines. They wrote very favorably about the plant at first and have just placed an order for the third machine of the same size as the first two, and thus verify their opinion formed over a year ago, when they said they could not recommend it too highly.

THE COLLIERY ENGINEER CO'S. CORRESPONDENCE SCHOOL.

The Colliery Engineer Company, of Scranton, Pa., have just issued the following circular:

"The offices of The Colliery Engineer Company, proprietors of 'The Colliery Engineer and Metal Miner,' 'Home Study,' and The International Correspondence Schools, in the Coal Exchange Building, Scranton, Pa., were partially destroyed by fire on Sunday morning, August 30, 1896.

"Fortunately, our printing plant was in another building, and we had reserves of all instruction and question papers, drawing plates, and other supplies and stationery used in the schools in still another building, so that our business will not be seriously interfered with.

" 'The Colliery Engineer and Metal Miner' and 'Home Study' will be out within a few days of the usual time, and we are already (September 2, 1896) conducting the instruction in our schools as usual. We have secured quarters on the three upper floors of the new Mears Building, corner of Washington avenue and Spruce street, Scranton, and are now prepared to enter new subscriptions to our publications and also to enroll and commence promptly the instruction of new students in our schools, as before the fire. Our new offices are even more convenient and commodious than those which we have been compelled to leave by the fire, and we expect to occupy them until the completion of our new buildings, now being erected on Wyoming avenue. Patrons of our publications and students of the schools visiting Scranton are invited to call upon us in our new quarters."

THE WURTS SWITCHES AND CIRCUIT BREAKERS.

The Westinghouse Electric and Manufacturing Company are to exhibit at the St. Louis convention, in October, a complete new line of switches and circuit breakers designed by Mr. Alex. Jay Wurts. The instruments are remarkable for ingenuity and tasteful design, and, it is claimed, will entirely revolutionize the trade in this class of instruments. The switches are especially remarkable for their novel method of making contact and for their great carrying capacity, occupying, as they do, only half the space of an ordinary switch. The circuit breakers are designed on entirely new principles, every detail of which has been most carefully worked out and perfected by the inventor. The distinctive features are the absence of contact jaws and solenoid, the delicate ease of adjustment over a wide range and the ingenious manner in which all possibility of burning at the main contacts is avoided. A beautifully illustrated pamphlet, descriptive of the instruments and new principles involved, is now being prepared and will be ready for distribution.

MR. ASTOR'S NEW ELECTRIC LAUNCH "UTOPIAN."

Mr. John Jacob Astor's handsome new electric launch Utopian went off the ways from Ayer's shipyard, Upper Nyack, on Sept. 10.

The Utopian is one of three electric launches owned by Mr. Astor. Her cost will be from $18,000 to $20,000. She is a twin-screw auxiliary launch, 72 feet over all, 12 feet beam, 3 feet 6 inches draught, and was designed by Charles D. Mosher. The motive power is electricity, and the boat will be driven by two 25 horse-power motors, built by the Riker Electric Motor Company. She will also have auxiliary sail power. Mr. A. W. Johnson, electrical engineer, will have charge of all the batteries and the machinery in general. Mr. Astor will usually run the launch himself.

The boat will have a searchlight of 10,000 candle-power, and be lighted throughout by electricity. She was built to make sixteen miles an hour. Her first trip will be to "Fern Cliff," at Rhinecliff, where her batteries will be placed at Mr. Astor's boat house, built for his electrical launches.

ENCLOSED ARCS IN DRY GOODS STORES.

Several large firms in the dry goods line have lately thrown out their open arc lamps and substituted enclosed arcs in their place on account of the trouble from falling sparks which frequently endangered their valuable stocks. The Board of Fire Underwriters strongly favors the enclosed type of arc lamp, and the Electric Arc Light Company, who are the manufacturers of the "Pioneer" 150 hour lamp, have their hands full, according to all accounts, filling large orders; and find

their new and enlarged quarters already being crowded to their utmost capacity. They need not guarantee immunity from falling sparks, as the very construction of their enclosed arc makes any such accident a practical impossibility.

NEW YORK NOTES.

"ELECTRIC POWER" has been discontinued.

THE AMERICAN MOTOR COMPANY, Hoboken, N. J., is in the market for two or three hundred induction coils giving a three-eighth inch spark.

MR. L. T. LEVY has been appointed New York agent for the Massachusetts Fan Company, of Boston, with headquarters at 109 West Fifty-seventh street.

THE C & C ELECTRIC COMPANY, 143 Liberty street, has recently been awarded the contract for the installation of a 50 kilowatt direct connected plant at the Bijou Theatre, this city.

THE SUMMERHAYS COMPANY has been formed at Rochester, N. Y., with a capital stock of $10,000, to make gas and electric fixtures and supplies. The directors are M. Hirshfield, C. B. Griffith, and C. L. Hirshfield.

THE MANHATTAN ELECTRIC LIGHT COMPANY, which takes in the old company of that name and the Madison Square Light Company, has been formed, with a capital stock of $1,500,000. The directors are R. R. Bowker, E. A. Leslie, H. M. Edwards, C. S. Shepard and F. Enos.

LONG BURNING ARCS.—The General Electric Company has in press a little booklet on its long burning arc lamps, handsomely illustrated. The subject is treated from the standpoint of the convenience and economy to the station manager and the customer, by the use of these one hundred and one hundred and fifty hour lamps. Copies of this booklet will be ready for distribution in a few days, and our readers can receive them on application to any of the sales offices of the company or directly to the Supply Department at the Schenectady office.

MR. ELIAS E. RIES, formerly of Baltimore, Md., has removed to New York City, and has opened an office as consulting engineer and electrical expert, at Room 1031, Temple Court. Mr. Ries is well and favorably known to the electrical profession as a scientific investigator and technical expert of no mean ability, and there is scarcely a line of practical electrical development in which he has not done valuable original work. Mr. Ries is an active member of the American Institute of Electrical Engineers and other learned societies, has been a frequent contributor to the electrical and engineering press, is himself an inventor of marked capability, and has an extended practical experience which well qualifies him for his new field and which fully merits the success that we have no doubt he will reap.

JOHN SIMMONS COMPANY, 106-110 Centre street, are making a specialty of several lines of iron pipe brackets and poles for street railways and illuminating purposes. Their latest production is the Excelsior railway bracket, which is made entirely of malleable iron fittings and iron pipe and is so constructed that it may be shipped entirely made up. The main feature of this bracket is a filling piece between the brace and arm, which, upon removal, allows the bend of the brace to slide through the clamp fittings. This construction permits of crowding the bracket into a very small space, obviates packing and makes handling easy. Its cost is well within limits. The John Simmons Company have been identified with the wrought and cast iron pipe and fitting trade for many years, and are probably the oldest and largest house of the kind in this country. They carry a large and varied stock of wrought and cast iron pipe, fittings, valves and supplies for steam, gas and water purposes, and especially a full stock of all goods in their line suitable for electric light stations and plants, electric railways, etc. Their extra heavy screwed and flanged fittings for high pressure modern steam plants are of the celebrated "Jarecki" make, the John Simmons Co. being the agents for this well known brand of fittings, valves, cocks and tools. This firm will cheerfully give estimates on piping for every purpose—steam, gas, water, etc., also on poles and conduits. The offices and salesrooms of the John Simmons Company are at 106 to 110 Center street; their factory, pipe cutting and machine shop occupy the entire buildings 155 to 157 Leonard street; and to facilitate the direct handling of their enormous output, storing and shipping of pipe, they occupy the bulkhead at 381 South street, New York.

WESTERN NOTES.

THE ELECTRICAL APPLIANCE COMPANY are making a large number of sales of their new telephone switchboard. It has, they claim, a number of very desirable features exclusively its own, and is in every way a practical and serviceable board.

MR. W. A. KREIDER, manager of the Chicago Office of the Ball Engine Company, Erie, Pa., 1526 Monadnock Block, has closed orders within the past week for one 100 horse-power and one 60 horse-power engine to go to Geneva, Ill.; one 100 and one 50 horse-power engine to go to Wauwatosa.

MINNEAPOLIS POWER.—The Minneapolis City Council has granted the St. Anthony Falls Company a franchise to run electric light and power wires on the streets of the city. This company is the one that is building the new dam at Minneapolis, and much of the power from the water wheels will be converted into electricity and distributed over the city to furnish light and power.

MR. J. H. PARSHALL, Detroit, representative of the Ball Engine Company, Erie, Pa., has been successful in closing several contracts for his company during the past three weeks. He has secured orders for one 100 horse-power engine for the Toledo Glass Company, Toledo, Ohio; two 50 horse-power engines, direct connected to Walker dynamos, for W. H. Millikin for new hotel building, Bowling Green, Ohio; two 70 horse-power engines, direct connected to General Electric generators, for Hammond Building, Detroit, Mich.

PHILADELPHIA NOTES.

THE ART CLUB.—Wilson Bros. & Co., Drexel building, have completed plans for a new power house for the Philadelphia Art Club, on Broad and Locust streets.

MR. JAMES G. BIDDLE has removed from 944 to 910 Drexel Building, and has also 644 as his new telephone number. He has just been appointed agent for the Ward-Leonard Electric Company, and will fill orders for Carpenter enamel rheostats.

NEW ENGLAND NOTES.

MR. F. S. BURKE, manager of the Crown Woven Wire Brush Company, of Salem, Mass., starts on a Western trip this week. He informs us that trade is picking up with them, and that there is every indication of a good fall and winter business in their line. The company have enlarged their producing capacity, and are manufacturing everything in woven wire brushes.

ADVERTISERS' HINTS.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY continue to advertise their I-T-E circuit breakers and claim that the principles of their construction render them superior to anything in that line.

CHARLES N. WOOD, 180 Summer street, Boston, is offering a few three or four turn armatures for G. E. 800 motors at reasonable terms.

McEWEN ENGINES AND DYNAMOS are manufactured for belt driven and direct connected service. Their illustrated catalogue is well worth sending for and describes in detail some of their most popular types.

THE BERLIN IRON BRIDGE COMPANY illustrate a machine shop designed and built by them for the Bridgeport Machine Tool Company. This is but one of the many structures which stand as monuments to the excellence of design and construction of this company.

WARREN WEBSTER & COMPANY describe in a "straightforward little booklet" the advantages gained by installing their system of steam heating.

THE WESTINGHOUSE MACHINE COMPANY publish a list of engine sales for July in one of the smallest countries of Europe, demonstrating quite conclusively its popularity with expert engineers.

THE ELECTRIC APPLIANCE COMPANY are enabled to give their customers the benefit of a reduced cost in manufacture of the famous "Paranite" wire. The reduction is due to the large quantity produced and not to any cheapening of material.

THE CENTRAL ELECTRIC COMPANY are bringing out another novelty in the shape of a reflector.

THE INDIA RUBBER AND GUTTA PERCHA INSULATING COMPANY call attention to the fact that Habirshaw wires were used in the Siegel-Cooper "Big Store." This only serves to swell the list of large installations for which this company have furnished the wires and cables.

Department News Items will be found in advertising pages.

THE

Electrical Engineer.

Vol. XXII. SEPTEMBER 23, 1896. No. 438.

ELECTRIC TRANSPORTATION.

STATEN ISLAND'S RAILWAY SYSTEM.

The Staten Island Shore.

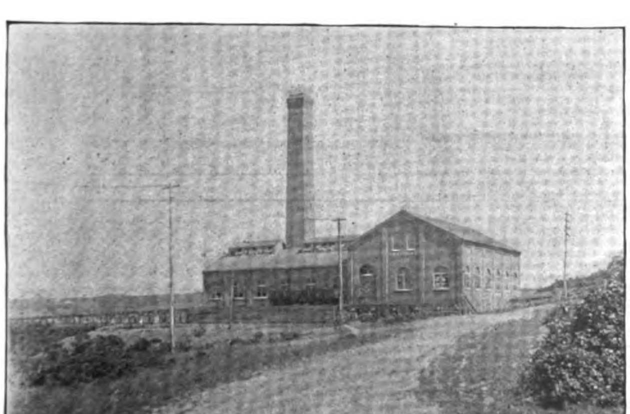
NE more resort is about to be added to the large number already in the vicinity of Greater New York which have been made accessible by the adoption of the trolley system. Midland Beach is the name given to a portion of the southeast shore of Staten Island which is undergoing extensive alterations and improvements at the hands of the Staten Island Midland Railway Company, who are also extending their system to various towns throughout the interior of the island.

Heretofore it would have been impossible to find a spot within a few miles of New York which was so devoid of any transit facilities as was Staten Island up to a year ago, and to this reason alone may be ascribed the almost total lack of development of this island which can boast of more natural beauty than any other suburb of New York.

Somewhat over a year ago the Staten Island Midland Railway Company purchased two small railway lines which had been built previously, and secured franchises for a number of new lines in the interior of the island, all of which are being developed into an extensive system of rapid transit, which will eventually connect all the principal points in the island.

LOCATION OF RAILWAY LINES.

The company's lines comprise at present twenty-two miles of single track, all of which is now in operation. Six and one-half miles of this track is double and work is being pushed on the principal lines which are being double tracked as fast as possible. From the ferry landing at St. George the line

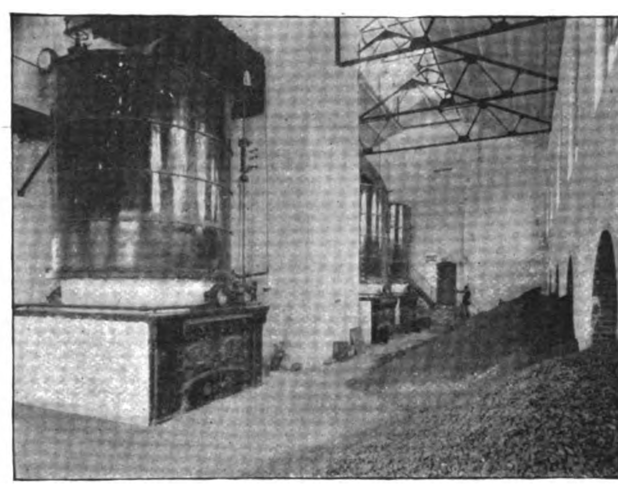


POWER HOUSE, MIDLAND RAILROAD, STATEN ISLAND.

runs to Stapleton and thence by way of Broad street and Richmond road to Concord, where the car house and offices of the company are located. Here the road branches, one line running on the Richmond road to the village of Richmond. From this line another branch turns off opposite the Moravian Cemetery and runs directly to Midland beach. The other line runs from Concord by way of the Clove road and Richmond turnpike to Prohibition Park, and thence on Jewett avenue to connect with the Bergen Point ferry. Crossing the latter line at Castleton Corners is another branch which starts at West Brighton and runs in a southerly direction to Eckstein's brewery. These lines, with the exception of a short distance from Stapleton to St. George, are now in regular operation.

LINE AND TRACK CONSTRUCTION.

The line is constructed partly with span wires and partly with single brackets, the poles being of wood. Three feeders of 500,000 circular mils section run from the power house to the three centers of distribution. The track is laid with 60-pound T rail, except for short distances in passing through villages, where a rail of the girder type was required by the authorities. In such places 90-pound girder rail was used.



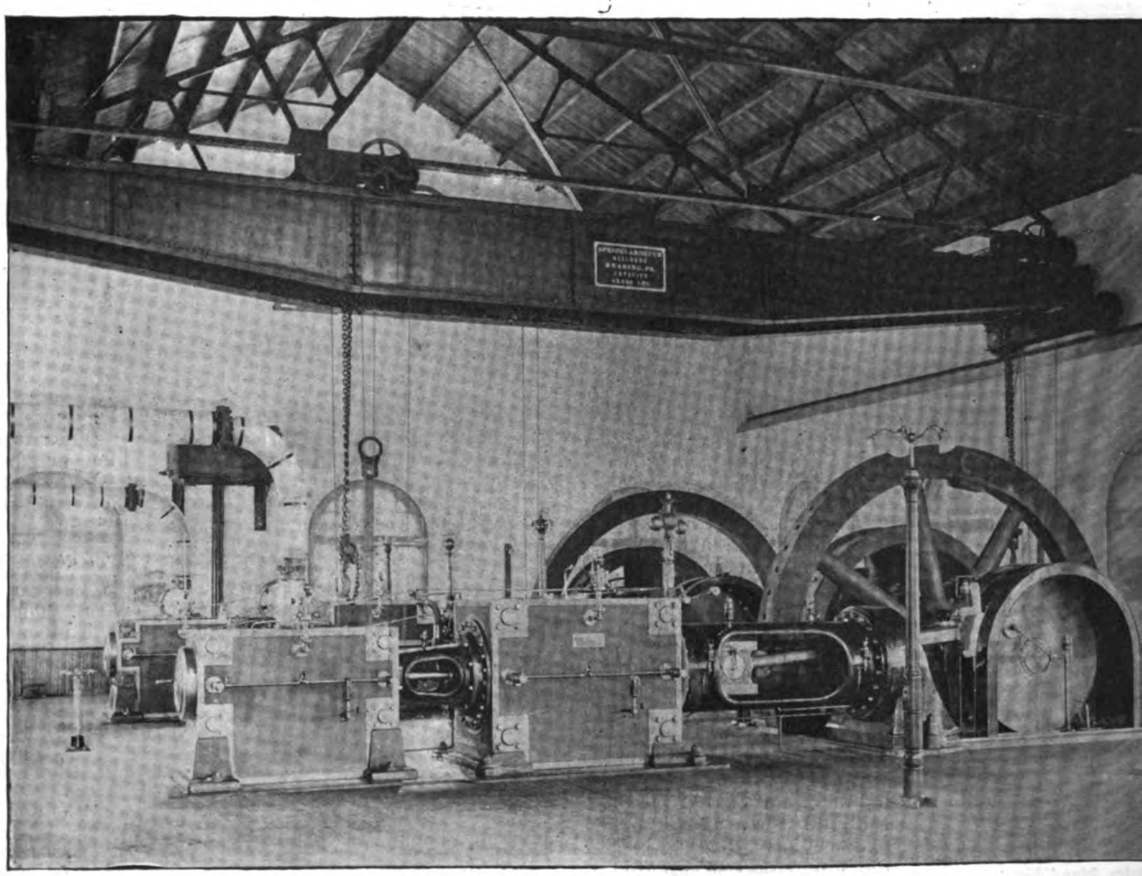
BOILER ROOM, MIDLAND RAILROAD POWER HOUSE.

In order to interfere with driving as little as possible, the plan has been adopted where the roads are narrow, of placing the tracks close to the sides of the road, leaving the center unobstructed. Where this is done side brackets are used instead of span work. Most of the streets over which the company's lines run have macadam pavement which has had to be renewed after the tracks were laid. This kind of pavement has been found to make considerable expense to replace as the large foundation stones cannot be used again on account of their interference with the ties. All the material taken out is replaced with small broken stone.

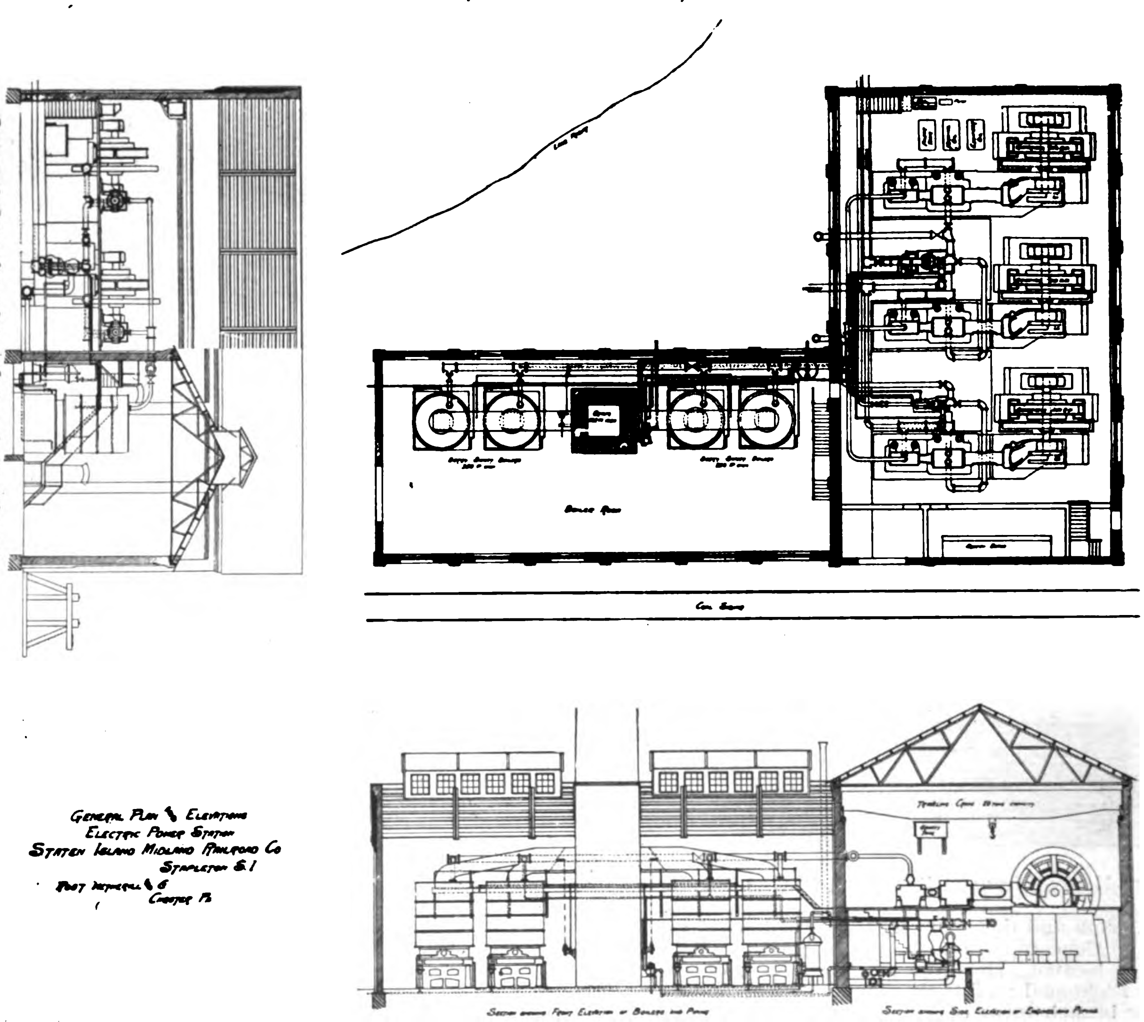
POWER HOUSE AND GENERATING PLANT.

The power house of the company is located a few steps from Grassmere station on the line of the Staten Island Rapid Transit Railroad. On one side is an elevated siding where coal may be dropped from cars directly into the boiler room, and at the rear is a lake of fresh water from which water for boilers and condensing engines is obtained. The power house, outside the advantage of easy access for fuel and water, is especially favorably connected for the economical distribution of current to the different lines of the Midland System, being practically at the center of distribution of power. The general plan of the building and the disposition of the machinery is shown in an accompanying illustration.

The building is of brick, the engine room being 54 feet 6 inches by 88 feet, and the boiler room 39 feet 4 inches by 84 feet. The engines and boilers are from the works of Messrs. Robert Wetherill & Co., of Chester, Pa. They are of the tandem compound condensing type, unusually strong in construction and especially designed to withstand the heavy strains of railway service.



Generating Plant, Midland Railroad, Staten Island.



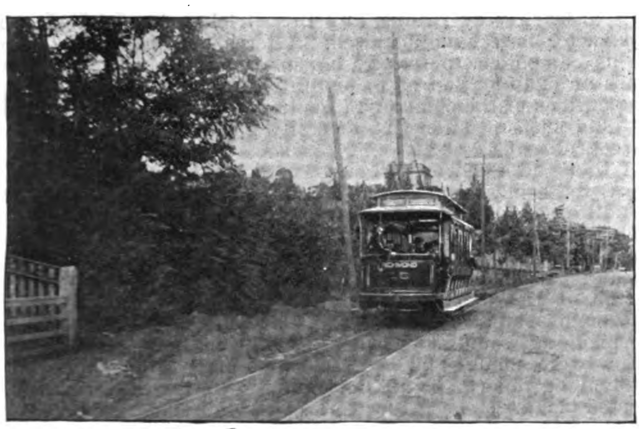
Plan and Elevations, Staten Island Midland Railroad Power Plant,

The cylinder dimensions are 16 inches and 30 inches by 48 inches, the speed being 100 revolutions per minute. The capacity of each at 150 pounds pressure is 500 horse-power, and each engine is directly connected to a 300 kilowatt General Electric six-pole generator. The condensers were built by the Worthington Company, and are located in the basement, which, in this station, is unusually well lighted and ventilated. The piping is of the strongest and most approved construction and is placed with a view to accessibility for inspection and repairs. The main pipes to the engine are of hammered copper and are bent in long curves to reduce the steam friction.

The boilers are an especially interesting feature of this plant. They are of a type rather new in railway work. They are known as the "Berry Boiler" and are manufactured exclusively by Messrs. Robt. Wetherill & Company, and consist of two vertical cylindrical shells, united at the top by a crowned ring and at the bottom by a conical crown-sheet. Tubes radiate from the inner to the outer shell, uniting and bracing them and forming a structure of great strength.

The gases, rising from the fire in the internal combustion chamber, are deflected by a fire brick arch placed in the internal flue, and pass through the tubes to the outside flue, then upward and inward through the middle section of tubes to the internal flue, thence upward and outward through the upper or superheating tubes, thence upward and inward over the top of the boiler to the stack. This boiler has proved remarkably economical in the consumption of fuel and in the attendance required.

The switchboard is of the latest and most approved design. There are three dynamo panels, one for each generator, a middle or totalizing panel and three feeder panels. The totalizing panel contains an ammeter for indicating the total flow of current and a recording wattmeter. The recording wattmeter is an extremely useful accessory to a power station, as it enables the engineer to compare readily during any given period the power output of the station with the coal consumption.



ALONG THE OLD "KING'S HIGHWAY," STATEN ISLAND.

The oiling of all the machinery is accomplished automatically by means of a gravity lubricating system. A large elevated reservoir is located at one end of the station from which pipes run to all bearings. From the bearings it is caused to flow through a filter in the basement to a collecting reservoir, from which it is again pumped up to the feed reservoir. A great economy in oil consumption is obtained by this system.

The station is provided with a twenty-ton traveling crane made by Spiedel & Roper, Reading, Pa. This device makes possible the handling of the heaviest machinery in case of emergency with little or no loss of time.

CARS AND CAR HOUSE.

The company have forty cars, twenty-five of which are long open cars and fifteen box cars. These are equipped with the General Electric Company's 25 horse-power motors and accessories. The car bodies are handsomely finished and were built by the St. Louis Car Company. In connection with their excursion business the company are having a parlor car built, which may be chartered for the use of trolley parties and excursionists. It will be on a smaller scale, exactly similar to the parlor cars on steam roads. The company's new car house which is now in course of construction is located at the Concord junction of the line, which is about at the center of the system. A separate office building is also being erected at this point. The car house is a brick structure 110 feet wide and 300 feet long. It is separated into three distinct sections by two fire walls which run lengthwise through the building. It contains eight tracks, and those in the central section of the building are arranged so as to run entirely over pits.

The entire road is being pushed to completion as rapidly as possible, and before another summer it will have added a new direct excursion from New York, besides providing an excellent system of transit for the residents of Staten Island. The officers of the Staten Island Midland Railroad Company are James C. Hinchliffe, president; B. H. Throop, vice-president; M. J. Wightman, electrical engineer; W. B. Rockwell, treasurer and general manager; E. G. Wightman, secretary.

THE USE OF OLD RAILS AS UNDERGROUND CONDUCTORS.[1]

BY F. O. RUSLING.

WHILE the writer was the superintendent of the Buffalo Railway Company, serious indications of electrolysis of the pipes within a half mile of the power house made it necessary to call in expert advice to put a stop to the trouble. A careful and thorough electrical survey was made of the entire district. This was a long and difficult matter since there were three systems of natural gas pipes, two of illuminating gas, one of water and two conduit systems.

Although the pipes were already connected to the negative bus bar by large copper cables, it was found that these were entirely inadequate and that there were two points where the pipes at heavy load were 3 to 5 volts positive to the adjacent rails. One of these points was 1,500 feet north and the other 1,800 feet east of the power house.

The expert calculated that until extensive changes could be made in rail returns, the former point would deliver about 1,000 amperes, and the latter about 3,000. To bring this current to the dynamos with but 5 volts loss would need over $8,000 worth of copper. While hesitating over this large expenditure, it occurred to us that there were about 300 tons of old tram rails on hand that might be used for the purpose. These were flat, center bearing rails, originally weighing 56 pounds to the yard, but worn down to 50 pounds or less; they were high in carbon, hard and brittle.

The best scrap price obtainable was $8 per ton, delivered. Our expert carefully tested their conductivity with 1,000 to 1,500 amperes, using an instrument reading to one-thousandth of a volt in order to secure accuracy. As the showing was satisfactory, he persuaded us to let him try the rails on the 1,500 feet length which would require four rails in parallel to give the desired results. As he guaranteed to bond them so as to make a continuous conductor, he was allowed to go ahead. A trench was dug between curb and sidewalk and a continuous trough of rough lumber put into it.

The rails were bolted together in pairs back to back and arranged so that the end of one rail was at the center of its mate. The bonding was effected by scraping contact spots with a file near the end of each rail and amalgamating them with the Edison solid alloy. A steel washer ¼-inch thick, $1^{3}/_{16}$ inches inside diameter and 4 inches outside, was dipped into hot insulating compound and placed against one rail so as to inclose the contact spot. The hole in the washer was then filled with the Edison-Brown plastic alloy, inclosing an amalgamated steel spiral spring. The upper rail was then bolted on and the completed conductor lowered to bottom of trough, resting on one edge so that gravity would maintain the contacts. It will be evident that with this arrangement, two of the bonds on any one rail would have to give way before the circuit could be broken; each bond was made sufficient to transmit 1,500 amperes. When the second set of rails was lowered into place, the trough was filled with a hot insulating compound and a cover nailed down. This compound was cheaper and better than asphaltum; it remains viscous even in cold weather and has high insulating qualities. It is a product of petroleum distillation much lighter than asphaltum and costing about $25 a ton.

This four rail conduit was connected up and carried at heavy load 1,100 amperes, 1,500 feet with a loss of but 4 volts. This result was so surprising that our expert suspected his instruments were wrong and sent them back to Weston for recalibration; they were returned, but proved that the measurements were correct.

To appreciate the magnificent performance of these old rails and their bonds, I need only say that to give the same result it would require 3.55 square inches of copper, and 1,500 feet of this would weigh 20,532 pounds and cost, at 12 cents per pound, $2,462.83. Our four rail lengths weighed 50 tons and cost as scrap but $400. The resistance of steel as compared with copper is usually considered to be between 7 to 1 and

[1] Read before the N. Y. State Street Railway Assoc. at Binghamton Sep. 8, 1896.

9 to 1, but this including 50 bonds in each length was about 5.63 to 1. The tests proved that the plastic bonds actually did make an "electrically continuous rail," and after a year's service they are still maintaining their conductivity. This is more than can be said of any copper bond ever used. It will be noted that steel like this even at $30 per ton would be cheaper than copper as a conductor.

Our expert was then told to go ahead with the fourteen rail conduit. As the steel was so hard and brittle, a great deal of time was required to file the contact spots and to bore holes for the bolts to hold them together, so another method was adopted. In the power house is an air compressor for cleaning out armatures and removing dust from the boiler house walls. An iron pipe was connected from the air reservoir to the yard, and a single layer of rails, bottom up, was put on each wagon. Each load was carried into the yard and the contact spots were rapidly cleaned with a reciprocating pneumatic tool, borrowed from a boiler shop.

To avoid drilling the rails, pieces of ¾-inch iron, about 24 inches by 8 inches, were placed in the trough every 15 feet. These were bored at the ends for a pair of countersunk ¾-inch bolts and had four contact spots cleaned with an emery wheel. On these were laid the plastic bonds and four rails side by side, with base down.

The spaces between the treads were just right for a second layer of three rails bottom side up. Then another set of bonds and an iron plate ¼-inch thick, 20 inches by 8 inches. On these more bonds, other layers of four and three rails and finally a ¾-inch by 24 inches by 8 inches top, bolting all layers together. The sides of the trough were but ½-inch from the rails between clamps so as to save wasting insulating compound, with wider spaces to accommodate the clamps. Rail joints were broken as before.

This construction allowed very rapid and satisfactory work compared with the first. The performance was also satisfactory, as the fourteen rails transmitted 3,250 amperes, 1,800 feet with but 4 volts drop; an insulated pilot wire was put down with this conduit and permanently connected with a voltmeter in the power house. The rails used in this conduit weighed about 210 tons, which at $8 would amount to $1,680.

It would require 12.48 square inches of copper to equal the 70 square inches of steel. This copper, figured at 1,000 feet by one square inch weighing 3,854.2 pounds, would weigh 86,580 pounds, and at 12 cents per pound would cost $10,389. The total cost of the rails and bonds for both conduits was about $3,322, as against $12,852 for equivalent copper. The labor to install the copper would of course be less, but on the other hand, we had the rails in stock and the only actual outlay was for labor, bonds, lumber, bolts and insulating material. I have not the details of these now at hand; my recollection is that the total expenditure did not exceed $2,500, and that we thus secured results which would otherwise have cost nearly $15,000.

From my experience with copper bonds I should not advise the use of buried rails for conduits if copper is used for connections. Even when new it is impossible to get the full conductivity of the rail and the contacts get worse and worse as time passes. The copper when covered with the damp earth will oxidize at a rate determined by the composition of the soil and the amount of current transmitted. But following the lines indicated on our second rail conduit, any road with a lot of old rails on hand can cut down its transmission losses at a slight cost. This subject is well worth careful consideration on the part of railway managers.

HOW CAN WE PREVENT ACCIDENTS AND INCREASE THE GENERAL EFFICIENCY OF EMPLOYEES?[1]

BY W. W. COLE.

THERE are certain accidents which occur upon the best regulated railroads, that can never be averted. They are the results of two agencies: Fate and the fool killer. And there are others which occur through defective apparatus, poorly conditioned motormen, or gross carelessness of employés. One of the first and most important requisites to improving the efficiency of the road and preventing accidents is in the selection of employés, and to this end the application blank is an important factor, and such questions should be asked as to generally outline a man's past.

The question, Do you own real estate or personal property? is important; as a man who has accumulated property while working for small pay, must necessarily be economical and appreciate laws governing the protection of property, and is apt to have care for the property of others.

To what extent are you in debt? I think we will concede that a man who is in debt will not only prove a nuisance to a company, but be apt to take but a short lived interest in his work and become careless. Constant requests are made upon a company to compel a man to back his bills, and a company loses many friends unless such matters are given attention.

Do you use intoxicants, and have you ever been addicted to the use of intoxicants? These questions need no comment.

What are the highest wages you ever received? Now the best man for a place is the satisfied man, who thinks he is doing well. And a man who has commanded higher wages than you pay, is sure to believe sooner or later that you do not appreciate his real value, and he becomes dissatisfied, and will either take more interest in looking for another place, or in airing his troubles before the other men, and he becomes careless in his duties either way.

The other questions are all such as will tend to delineate a man's stability and character. I believe that all men should be placed under at least two hundred dollars bonds, as it not only has a restraining influence upon the men, but so many business men in order to get rid of a man with a little trouble, will give him a first class recommendation, but they will hesitate to go upon his bond unless they know something of his ability, reputation and personal habits. When you employ a man under bonds, you have practically got him registered with his friends' approval.

Great care should be taken in the choice of instructors of motormen and conductors, and to the end it is well to keep a book recording all acts of disobedience or carelessness of each employé and then select as instructor the men as having the best record. It has been my experience that a new man is apt to learn very readily any little tricks of carelessness his instructor may have acquired. After a man has been turned in as competent to run by his instructer, I think he should pass an examination as to his duties, and upon the rules and regulations of the company. I submit examination papers containing such questions as generally apply to the operation of street railroads.

I think all motormen should be furnished with a blank report, to be filled out each evening, or after his run, as to the condition of his car, and report all trouble with breaks or any defects with running gear or apparatus, and place his report on file for the foreman of the shop, who should have an immediate inspection made of the car reported.

One of the most important preventives of accidents is a thorough system of shop inspection, and such reports should be made as would show when a car is in shop, just what repairs were made, and the time and material consumed. A system of reports in all departments that will form a connected chain, to check the work of the individual, is of benefit when such reports are not complicated and are always attended to. I do not claim that such a system will make a good man out of a poor one, as my experience has been that it is much easier, and the result more satisfactory, to discharge the poor man and get a good one in his place, as the process of educating a careless or incompetent man is too much like the horse that fed on excelsior. When he got used to it and relished it he died.

Accidents are frequently occurring from loss of power, when it is most needed. No road from an economical point of view should try to run too close on a theoretical consumption of power. This is especially so in the case of small roads, operating from five to fifteen cars, and is of special significance where there are grade crossings; as in case a trolley flies off, it is apt to be replaced in a hurry with the power on, and this means a sudden jerk, especially on a jump-over crossing; and where a road is running close to its full power capacity, and the power goes off, it is very likely to be several minutes before the circuit-breakers can be kept in and the car got under motion again. When it becomes necessary to reverse a car to prevent an accident, it is very liable to pull the circuit-breakers out at a most critical moment. I doubt if a too slow schedule decreases the number of accidents, as I have found that on a division where the cars run slow the public are inclined to take dangerous risks, rushing in front of moving cars, that they will not take where the cars are moving at a brisk rate of speed.

To prevent accidents and increase the general efficiency of employés, select the employés scientifically and with care; provide a good system for your car inspection and have a surplus of power.

[1] Read before the N. Y. State Street Railway Association, Binghamton, September 8, 1896.—Abstract.

"LIKES IT BETTER." A reader in St. Louis says: "Some few months ago I sent for a sample copy of your paper, which I received and was very much pleased with. I have been taking your paper ever since from a book store. I like it better than the other ten cent papers."

THE BALDWIN ELECTRIC LOCOMOTIVE TRUCKS.

THE axles of the ordinary car truck are not driven, but the truck is hauled by a locomotive. Electric locomotive trucks have driving wheels, and therefore must be adapted to pull cars. This throws quite a different stress on the transoms and necessitates a much stronger and more rigid construction. In order that the motors may be reversible and interchangeable, they must drive the axles at opposite sides of the truck; this produces a distorting stress tending to put the

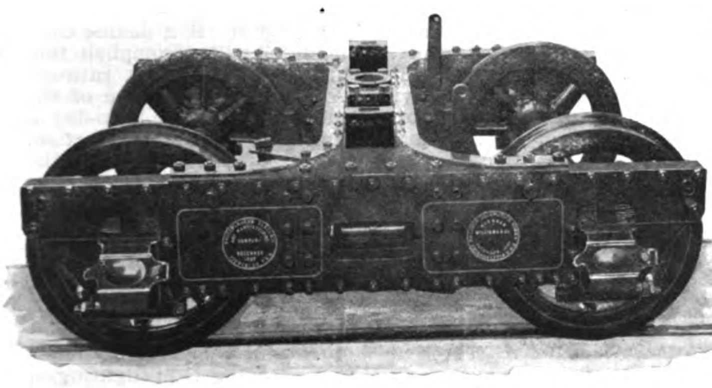


FIG. 1.—BALDWIN ELECTRIC LOCOMOTIVE TRUCK.

frame "out of square." Among the trucks specially designed by the Baldwin Locomotive Works, of Philadelphia, to meet the demands of electric locomotive or motor car work are the two illustrated in the accompanying engravings.

As will be seen, the transoms of the truck are provided with a substantial gusset to the side frame, and knees and brackets are introduced to hold the frame perfectly square and true, and enable it to withstand the distorting stress developed in the truck by the operation of the motors. Care is taken that the boxes and journals shall be of the proper form and size to adequate wearing surfaces, and that they shall be so fitted as to resist properly the shocks transmitted to them without being thrown out of line. The weight of the trucks and motors is supported on the journal boxes by means of suitable springs with limited range of motion. A swing bolster of improved design is introduced to carry the weight of the car; this is connected to the truck by suitable links, and provided with easy-riding double-elliptic springs.

For the purpose of gaining access to the parts of the truck, and for readily removing the wheels, axles and boxes, a swinging jaw may be arranged to form the outer pedestal leg. This is secured to the truck frame by a joint connection, and securely held in place by the pedestal-cap bolt. When desired, it can be lifted, and the released parts removed without taking the truck from under the car. The swing bolster and springs can be dropped down and taken out without disturbing any of the other details of the truck. The brakes are arranged

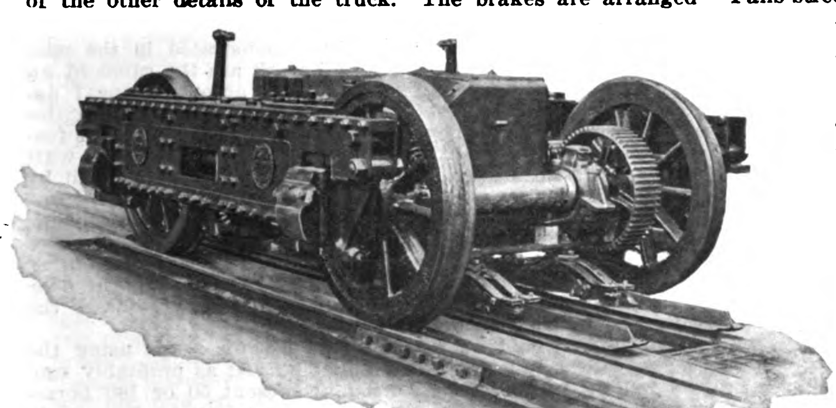

FIG. 2.—BALDWIN ELECTRIC LOCOMOTIVE TRUCK.

without brake-beams, so as not to interfere with the removal of the swing bolsters or motors. The motor hangers are so placed that the motors can be dropped out of the trucks without brake-beams, so as not to interfere with the removal of the swing bolsters or motors. The motor hangers are so placed that the motors can be dropped out of the trucks without taking down the swing bolsters or the brakes, and without removing the wheels or axles.

The workmanship in these trucks is equal to that in steam locomotive construction. All the bolts are turned taper to a driving fit in reamed holes, and all parts are well fitted with planed surfaces.

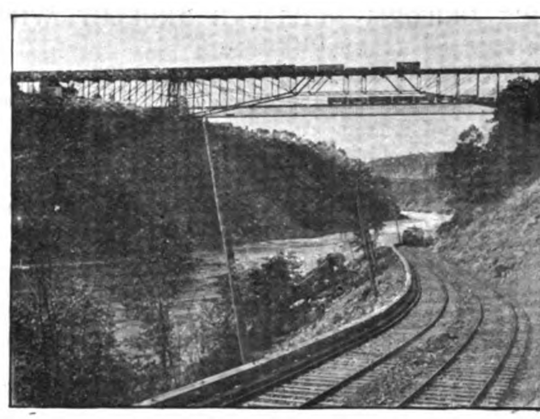
A parallel rod can be provided at small additional cost, if desired, as the strength of the design has been made with this in view. Where it is not desirable to use sand, and where the motors are to be started with full power, it is often best to use parallel rods.

Fig. 1 shows the truck for the Class 8-4-200 E locomotive. It is adapted for use with either the 200 or 100 horse-power motors. The wheels may be made forty-eight inches in diameter without increasing the wheel-base above seven feet six inches.

Fig. 2 shows the truck for the Class 8-4-100 E locomotive. It is adapted for use with either the 50 or 100 horse-power motors. The wheels may be made thirty-six inches in diameter without increasing the wheel-base above six feet.

RECENT TROLLEY WORK AROUND NIAGARA.

THE construction and successful operation of the "Gorge Road" at Niagara is one of the marvels of engineering skill of recent years, while it also displays in no small degree the encouragement given to capital to invest in new projects by electricity. The incorporated title of the owners of this line is the Niagara Falls and Lewiston Railway Company, of which Captain J. M. Brinker is president; F. C. M. Lautz, vice-president; R. W. Jones, treasurer, and H. P. Bissell, secretary. The road runs between the city of Niagara Falls and the village of Lewiston, a distance of seven miles. Not satisfied to



A VIEW ALONG THE NIAGARA GORGE TROLLEY ROAD.

take the beaten paths of travel, this road has been built through the beautiful Niagara gorge.

In Niagara Falls the cars of this road start at the foot of Falls street directly in front of the main entrance to Prospect Park of the State reservation. They run up Falls to Second street, and out Second street to Main over the tracks of the Niagara Falls and Suspension Bridge Railway Company. At the junction of Main and Second streets the "Gorge Road" cars strike their own tracks and continue down Second for one block and then across private property to the point where the road is depressed in order to cross the New York Central Railroad through a cut. Almost immediately upon emerging from this cut the beautiful panorama of the gorge is opened to view. For a distance of about 400 feet at a 9 per cent. grade, the cars descend the bank through a cut in the solid rock fully 75 feet high at the lower end. Then the descent of the slope of the bank commences to the cantilever bridge abutments, the grade being about 6 per cent. for 1,000 feet, 4 per cent. for 2,500 feet and 5 per cent. for 500 feet or more.

It is at the cantilever bridge that the roadbed assumes the level, at which it runs for almost the remainder of the route. This is about twenty feet up from the water's edge. A wooden trestle has been built in front of the bridge abutments, and on this the tracks are laid one within the other, so that only one car can pass this point at a time.

Along the whirlpool rapids below the bridges to the whirlpool, the perpendicular cliff has been blasted away to give the road a foothold, and cribwork has been built at one spot to save the roadbed from the wash of the rapids.

It is only this summer that the road has been operated over its entire length, but it has enjoyed a wonderful patronage. When the road was first operated power was taken from the Niagara Falls Hydraulic Power and Manufacturing Company, but upon the Niagara Falls and Suspension Bridge Railway taking power for the operation of its lines from the tunnel plant, the "Gorge Road" secured the service of that company's station and is now receiving its power supply from it, about 150 horse-power being used. The track is laid with 60-pound Tee-rail, connected at joints with bolt splice bars. At all curves the line is well guarded, especially as it ascends the slope from the cantilever bridge. All the way up the grade there is a double timber guard outside the outer track. The inner of these guards is 6 by 8 inches, while the outer one is 12 by 12 inches. The company now have 20 cars, 18 of which are of the open variety and two of them closed. These cars were made by the J. G. Brill Company, of Philadelphia. In the winter season the open cars are enclosed and heated, and furnish excellent facilities for viewing the winter scenery. The overhead line is of 00 trolley wire, and is divided into sections of about 1,000 feet, with independent circuit breakers. The track is bonded with "plastic" bonds.

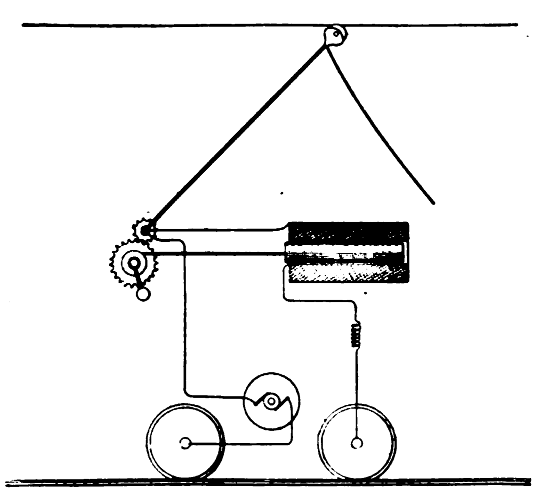
While the cars are thoroughly well equipped for rapid traveling, speed is not an essential feature, for a comparatively slow gait is necessary in order that the passengers may enjoy the full sublimity of the scenery along the line. The construction of the road was very expensive. The right of way had to be purchased, and the natural barriers of the gorge forced an immense expenditure in breaking the roadbed through.

The success the road has had since opening is very largely due to the efficient work of Mr. Joseph K. Brooks, who is its superintendent.

DYER'S UNIFORM PRESSURE TROLLEY WHEEL DEVICE.

It is well known that in the practical working of electric railway cars wherein the current is supplied by an under running trolley from an overhead working conductor a great range of adjustment of the trolley is required, the overhead working conductor being at some points, as in passing under bridges, lowered close to the roof of the car and at other points being elevated to a height of ten feet or more above the car-roof. By reason of this great range of adjustment it becomes desirable to produce means for maintaining the upward pressure upon the trolley which will give a practically uniform pressure throughout the entire range of adjustment of the trolley.

To secure the desired end, Mr. R. N. Dyer, of New York, has



DYER'S UNIFORM PRESSURE TROLLEY.

devised the arrangement shown diagrammatically in the accompanying engraving. This consists of a solenoid located in a circuit independent of that of the car motors. The coil of the solenoid is connected with the trolley through a speed multiplying gear, so that the minimum movement of the solenoid core will be required to effect the adjustment. With this arrangement the maximum efficiency of the solenoid and a nearly uniform pull is secured throughout the range of movement of the trolley.

The solenoid may evidently be replaced by a constant torque motor device.

POWER FROM THE TROLLEY CIRCUIT. IS IT PRACTICABLE? WHY DO THE FIRE INSURANCE COMPANIES OBJECT? WHAT SHOULD BE DONE TO OVERCOME THE OBJECTIONS?[1]

BY H. S. NEWTON.

An experience of several years in the erection and operation of power stations has led me to the conclusion that the chief point of interest connected with them in the eyes of the management is the relative size of their coal bills. In many sections of the country the saving of a ton of coal per day is equivalent to the interest on $20,000. If a device costing, say, $15,000 to install and operate, will accomplish this saving, it is clearly to the advantage of the street railroad manager to install this device. And as a consequence of the realization of this fact, the railroad power station is to-day a combination of all that is economical in steam construction.

It is my intention to first point out to this convention the chief advantages possessed by our railroad systems as producers of power for private consumption and then follow with a statement of the objections raised by the Board of Fire Underwriters and others toward its adoption throughout the cities of New York State. Hitherto the electric light station has figured as the chief factor in the production of power for stationary motors. It is too often hampered, though by circumstances of small units and insufficient reserve to consent to take hold on a large scale of a business necessarily offering what is, as compared with that accruing from lighting, a reduced margin of profit. In lighting stations, too, employing large engines driving many machines, the variation in load always attendant on the use of motors is also objectionable from the fact that the lights are affected to some extent. In these particulars the railroad station is prepared.

Take for example a station in one of our cities containing a 1,200 horse-power direct coupled Corliss engine held in reserve and estimate what could be done with this engine and its attached generator were it thrown into active duty on a private consumer's power circuit. Figure on an investment of $75,000 in the engine, generator, and other apparatus relating to the two. Then assume coal to be worth $3 a ton, and the engine to have a fuel duty of 3 pounds per horse-power per hour, we have coal consumed for each day of ten hours:

Eighteen tons at $3	$54.00
Cost of labor, engineer, fireman, and oiler, say	10.00
Oil and waste	2.00
Incidental repairs	10.00
	76.00
Add to this 10 per cent. depreciation for one day	20.55
And interest on the investment at 5 per cent	10.27
	$106.82

Then figuring on an ability to sell the output for 10 hours in the day at 2¾ cents per 1,000 watt hours, we have 1,200 horse-power for 10 hours equals 8,952,000 watt hours at 2¾ cents equals $246.18.

With cost of production as stated above, the net profit amounts to $139.36, a very fair sum to go toward reducing operating expenses.

I think it has been abundantly demonstrated in the past that long lines of shafting for mill work are the cause of an enormous waste of energy, and on that account alone I am sure that there are numbers of the smaller mills in our cities which would save money if they rented their power at a reasonable rate from the railroad circuit. The recording watt meter has been brought to a high state of perfection, and by its aid there is no necessity for the consumer to pay for one iota of current more than he uses. Then he can divide up his factory among several smaller motors, can run one or all of them as occasion may demand. This, too, with an outlay which should be inconsiderable compared with that the electric light companies would be compelled to charge were the power obtained from their circuits.

This plan would be feasible not only for shops using the very smallest of units, but it might be just as profitably considered by manufacturers using at present 50 or 100 horse-power steam plants and employing their own engineers. At 2¾ cents per 1,000 watt hours, were there 50 horse-power used uninterruptedly during the day, the charge would be a little over $10, while the presumption is that were a small engine and boiler used to move line shafting for the same shop, the inferior economy of the steam plant plus the increased power necessitated by loss in friction would more than overbalance in cost the bill sent in by the railroad company.

The small outlay required from the railroad company in

[1] Read before the N. Y. State Street Railway Association, at Binghamton, Sept. 8, 1896.—Abstract.

reaching consumers is another point to be urged in favor of supplying power from the trolley circuit. It is a noticeable fact that street railroad engineers are providing much more liberally for their trolley feeders to-day than they did on the introduction of electricity as a motive power and in consequence our lines are so well fed that the abstraction of a small percentage of power for outside use would hardly be noticed in the running of the cars. Then the close proximity of the feed wires on the railroad circuits and the short taps and small expense required to connect them to factories would be a strong card in the eyes of the consumer.

The objections as advanced by the Board of Fire Underwriters to the use of the trolley circuit for stationary motors seem to be embraced in one feature, the ground return.

Over in Syracuse we are using for supporting our various lines, some four or five hundred iron poles. Every pair of poles is to the trolley wire suspended between them a dead ground, and yet in the last three years, during which time I held my position on the street railroads there, we have never had one ground on these poles. And yet these insurance men tell us that they cannot find an insulation secure enough to warrant their insuring a building into which the trolley circuit runs, with every precaution taken for most careful insulation, without an addition to the premium such as I have noted.

To bring insurance bosses to our way of thinking and to gain entrance for the trolley circuit into the factories and workshops would seem to be an imposing task. These men have been known to yield to pressure, however, in other things, and there is always the rivalry and greed among them arising from competition to favor an effort in any direction. The power business itself is one that is assuming more importance every day, and with an assured profit in sight, the railroad companies (in this time of three-cent fare agitation) will not long consent to remain without their share of the spoils.

THE DAILY INSPECTION AND CARE OF CAR EQUIPMENTS.[1]

BY JAMES B. CAHOON.

In carrying out a system of daily inspection, or any system for the care of car equipments, we have in view a twofold object: (1) To prevent breakdowns when the car is out on the road, and the consequent annoyance to passengers, as well as the blocking of traffic and the throwing of the cars off their schedule time. (2) The reduction to a minimum of the repairs necessary to maintain the equipments in good working order and the prolongation of their life. We have, then, to, determine how we can best accomplish these objects and in so doing obtain the best results with the least expense.

Considering for a moment what we have to deal with, we find in the ordinary electrical car that we have two motors of fifteen horse-power or upwards, with their various connections, placed in the very worst possible position in which to operate machinery in motion, with occasional sticks, stones, wires, etc., thrown into them, and on rainy days and in the winter time to throw off the mud, slush and water from the wheels, and subjected to wide fluctuations in the power which they must produce under these unfavorable conditions.

In general there are three systems in vogue at the present time, the first being to let the motors take care of themselves until something gives out and then it is replaced and such repairs made as seem necessary at that time. Second, and the one followed by many of the smaller roads, is, when the car comes in at night, to have one or more men examine the boxes to see that they are filled with grease, rub off the commutator, and see that the brushes are not too far gone for the next day's use, and, if they are, to replace them with new ones, examine the trolley wheel and see that that is in good shape and see that the brakes are repaired properly, then the car is washed or wiped on the outside and is ready for the next day's run. Following this, whenever a breakdown occurs, the car is run over the pit and given a thorough overhauling. The brasses, pinions, and gears are examined, and replaced if deemed necessary, and the motor is painted if it so requires and put into fair shape, or, in some cases, it is taken down entirely and thoroughly overhauled.

The third system consists of a rigid daily inspection of the motors, trucks, and car-bodies, in all their parts, everything being gone over by competent inspectors and the car not allowed to go out if any defects exist. This last system seems to be the only one by which we can hope to get perfectly satisfactory results, but it can be elaborated so that the expense would be more than the gain, though as a rule I have not found this to be the case.

The system whose adoption I would advocate is that which we have put in practice on our road and suggested to some other roads, which from actual experience has shown itself to be an eminently satisfactory one. This system is as follows: A trip inspection, a daily inspection and a monthly inspection. The trip inspection may be made in one of two ways: If the car runs into the car barns at the end of each trip it may be gone over by inspectors ready to receive it, who examine the boxes, see that there are no signs of heating, that the grease cups are properly filled, that the armatures and fields are all right and that the brake mechanism is in proper condition. On small roads where cars are not run into the car barns, perhaps, until the end of the day, this inspection may be made by the motorman at the end of each trip, it being a brief one and can be made in a couple of minutes, and if anything is out of order the trouble can be remedied on the spot. To this end, as well as to any repairs en route, each car should be provided with a tool bag containing a small ball pein hammer, a 10-inch monkey wrench, pair of 8-inch pliers, and 10-inch screw driver.

The daily inspection: When cars are run into the car barns after the day's work is over, two inspectors board each car and go over every part of the car and equipment, removing dust and dirt from around armatures and fields as far as possible with a hand bellows, wiping commutator, removing brushes and seeing that they are in good order and the copper peeled back on them so they will not wear into the copper coating during the next day's run, thus avoiding the squeak which this would cause. Every electrical connection is carefully examined to see that it has not become jarred loose and if any defect exists in any part it is immediately repaired, if such repair will not involve over ten minutes' work; if it does, then the car is left over for the machinists to put in order on the following day. The same care is exercised in going carefully over all the nuts, bolts and washers, cotter pins, etc., connected with both motor and truck; brake rods are gone over and brake shoes examined and everything seen to be in proper working condition for the morrow. The car is then turned over to the car washer who goes over the outside of the car, cleaning all parts carefully, the inside of the car being swept out by the conductor who brings the car in, and the conductor who takes the car out in the morning cleans the brass work and windows and dusts off the seats and the inside of the car. In this manner we have caught a great many troubles just commencing which cost comparatively little to fix at that stage, but which, if allowed to continue, would have entailed quite serious outlay.

Third, Monthly Inspection: Once a month in rotation each car is run over the pit and motors dropped down, taken apart and thoroughly cleaned; gears, pinions and brasses, if they are so far worn that they will not last another month, are replaced. The armatures and fields are carefully cleaned and painted and the commutator turned down if necessary; in fact, the equipment is put into first-class order throughout, so that to all intents and purposes, it is as good as new when again replaced on the car. The car-body and trucks receive the same care and attention and are also put into first-class running condition.

We have found by experience that a shoe having sections of harder material cast in it has effected quite a reduction in the cost of brake shoes, the average life of these shoes being about three and a half times that of the ordinary cast iron shoe; these shoes lasting a little over two months on our road, while the old style cast iron shoe only lasted about 18 days.

A comparison of figures on our own road of the two different plans of the careful system of inspection and the old way of letting things go until they go to pieces, shows that the saving effected more than equals the total wages of the men employed on inspection and the machinists employed in the daytime repairing the cars. This, however, would not hold true on a large road, probably, but certainly the saving effected would considerably more than offset the wages of the men on inspection alone, and I believe that a system such as outlined above will, if carefully followed out, accomplish the best results with the least expense.

[1] Read before the N. Y. State Street Railroad Association, at Binghamton, Sept. 8, 1896.—Abstract.

ELECTRIC HEADLIGHTS

As a number of railroads in the United States are contemplating placing electric headlights on the locomotives in place of the present headlights, Theodore N. Ely, chief of motive power of the Pennsylvania Railroad Company, was asked whether his company contemplated doing the same thing, and he said that under no circumstances would the present system of lighting up the tracks ahead of the engine be changed.

In speaking of the use of the electric headlight, he said that the Pennsylvania Railroad experimented with this system sev-

eral years ago, and while it gave an excellent light, it would not answer the requirements, as on a two-track or a four-track road the rays from a locomotive coming in an opposite direction were so strong as to blind the engineer, and it would be some time before he got over it. Mr. Ely also said that of late years they have been reducing the size of the headlights for the locomotives. They were formerly thirty inches, but now are sixteen. Headlight oil, he thought, was more reliable and was cheaper, and he saw no reason for placing a dynamo on the engine for generating electricity for the headlight.—Philadelphia "Press."

AN ORE TROLLEY ROAD FOR CRIPPLE CREEK, COLO.

The arrival of Joseph B. Crosby, of London, England, at Denver, Colo., has brought out the announcement that New York capitalists have completed arrangements for the construction of an electric line for hauling ore from Cripple Creek district to Canon City, also for the erection of two mills and the building of a power plant which will illuminate the town of Cripple Creek and the big mines of that district. The estimated expenditure by that company in this proposed enterprise is $1,250,000.

This company, according to Mr. Crosby, has secured the right of way formerly held by the Canon City, Cripple Creek and Gold Belt Railroad. This road will be constructed at first from Canon City to Gillett, and the ultimate purpose is to push the line to Cripple Creek and beyond. The length of the road is 30 miles and the line will be used principally for the transportation of ore from the Cripple Creek district to mills which are to be erected at Canon City and Marigold by the New York syndicate. Work will be commenced on the trolley line immediately after election.

There will be ten trains daily on the trolley line. These trains will be made up of three ore cars and one passenger car. The hauling of the ore to the mills will be down hill and the promoters of the scheme estimate that but 30-horse-power will be required to operate the trains.

The grade of the proposed road is but 2 per cent. and the construction has been pronounced easy by engineers who have been in the field surveying the route. A good portion of the distance is through an open country.

The company also intends to take in the Bare Hills district, Freshwater camp, and numerous big properties by means of spurs. The rolling stock will consist of about 25 motors, 30 passenger cars and 100 freight cars.

The power to operate the road, as well as to illuminate the Cripple Creek district, will be furnished by an electric power plant which will be located at some point on the Arkansas River which is still kept from the public. This plant, it is estimated, will cost in the neighborhood of $400,000, including the transmitting power to the Cripple Creek district.

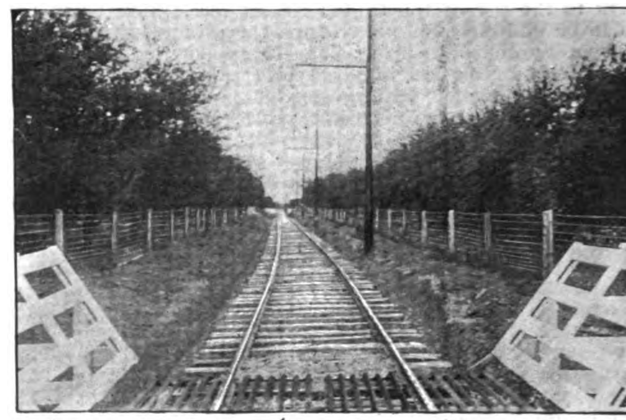
The mill to be erected at Canon City will have a capacity of 100 tons to begin with, and will require an expenditure of about $50,000. The plant will be constructed with the arrangement to increase to a capacity of 300 tons. Workmen will be engaged in constructing the mill while the building of the trolley line is in progress, and will be equipped with the latest improved methods in treatment of ores.

THE LEWISTON TROLLEY ROAD.

BY ORRIN E. DUNLAP.

NOW that the Lewiston and Youngstown Frontier Railroad is in operation, one can board a trolley car on the shore of Lake Erie, in Buffalo, and travel over electric lines from lake to lake, or, in other words, from Lake Erie to Lake Ontario. The three electric lines that make this really delightful trip possible are the Buffalo and Niagara Falls Electric Railway, the Niagara Falls and Lewiston Railway and the Lewiston and Youngstown Railway.

The Lewiston and Youngstown Frontier Railway connects the two pretty villages whose names have been incorporated in its title, but it is quite likely that the road will become better known as the "Old Fort Route," owing to the fact that it runs in close proximity to old Fort Niagara, the historic military post at the mouth of the Niagara River. In length this new road is seven and one-half miles, but an additional mile is to be built next spring to connect the road with a magnificent grove of white oak timber owned by the railway company on the shore of Lake Ontario adjoining the military reserve on the east, which is to be devoted to pleasure resort purposes. The road is a single track line, a 68-pound rail being used in its construction. From end to end the road is rock ballasted, the company owning the right of way, which is 30 feet wide. The Lewiston end of the line is in close proximity to the dock of the Niagara Navigation Company, where boats are taken for Toronto and down the St. Lawrence, and also adjoining the New York Central depot, where trains are taken for all points. From this point the road runs up into the village of Lewiston and when about 40 rods back from the river turns toward Youngstown, passing through many fine farms and beautiful orchards, as will be seen by the illustrations in connection with this article. Approaching Youngstown, the road is again diverted toward the river and runs through the principal street of the village close to the river bank, affording occasional beautiful glimpses of the scene where river and lake meet.



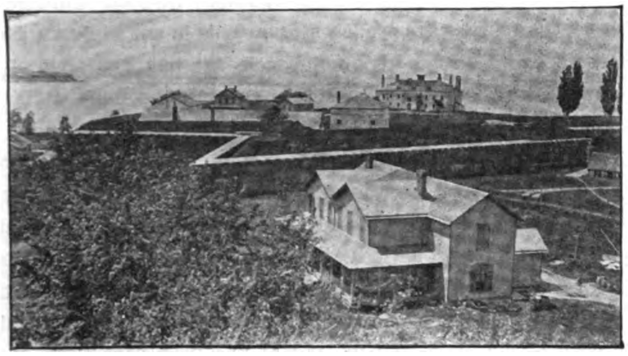
TROLLEY ROAD THROUGH A NIAGARA APPLE ORCHARD.

The contractors who built the road were Messrs Crage & Tench, while the electrical equipment was furnished by the F. W. Oliver Company, of Niagara Falls, their electrical superintendent being Mr. W. L. Adams. In both the villages mentioned the overhead construction is of span work, and on the line of the road through the country bracket construction is used. The trolley wire is 00, and was furnished by the Crefeld Electrical Works of Rhode Island. The power for the operation of the line is purchased of the Niagara Falls Hydraulic Power and Manufacturing Company, whose generating plant is on the canal basin in the city of Niagara Falls. To supply this power a 500,000 cm. cable is run down through the gorge on the poles of the Niagara Falls and Lewiston Railroad to the terminus of the line at Lewiston,

ROAD TERMINUS AT MOUTH OF NIAGARA GORGE.

and from this point a 0000 feeder runs 2,400 feet down the road toward Youngstown. Beyond this toward Youngstown the trolley acts as the feeder, the distance being about three miles. This makes about seven miles of the 500,000 cm. cable and about the same amount of the 00 wire. Thus it will be seen that the Youngstown end of the line is about fifteen miles from the plant which generates the motive power. The generator used was made by the General Electric Company, and is 90 kilowatt. To improve the service a second generator, which works in series with the first generator, is used as a "booster." This "booster" makes 750 revolutions per minute, and is found of great assistance in the matter of voltage. The voltage at the generator is 550, which the "booster" raises up so that the voltage at Lewiston is 580. Between the first generator and Lewiston the loss in voltage is about 250. The voltage at

Youngstown, about 15 miles from the generating plant, is 507. Mr. Frank G. Lott, the new superintendent of the Buffalo and Niagara Falls Electric Light and Power Company, is also in charge of the power plant of the Niagara Falls Hydraulic



FAMOUS OLD FORT NIAGARA ON THE LEWISTON TROLLEY ROAD.

Power and Manufacturing Company, which, as stated, furnishes the power for this road.

The president of the Lewiston and Youngstown Frontier Railway Company is Mr. L. D. Rumsey, of Buffalo, who has a beautiful summer home on the Niagara midway between Lewiston and Youngstown, and Mr. R. B. Goodman is superintendent.

POWER TRANSMISSION.

THE PIONEER TRANSMISSION PLANT, OGDEN UTAH.

THE Pioneer Electric Power Company, of Ogden, Utah, has within the past month placed a contract with the General Electric Company for a complete 5,000 horse-power, three-phase plant, covering a transmission of thirty-six miles, from Ogden to Salt Lake City.

The power will be obtained from the fall in the canon of the Ogden River, at a point almost within the limits of the city of Ogden. Across the head of the Ogden Canon a dam is to be thrown, and an immense storage reservoir formed, which will cover some 15 or 20 square miles of a valley in the mountains. From this dam to the power house is a distance of nearly six miles. The water will be carried through a six-foot pipe of wood for about five miles, while for the rest of the way it will pass through a six foot pipe of rivetted steel. These pipes are fitted at intervals with automatic relief and air valves to prevent the bursting or collapsing when the flow of water is varied by changes of load. The effective head of water at the power house will vary from 400 to 450 feet and the full capacity of the pipe line will be 10,000 horse-power.

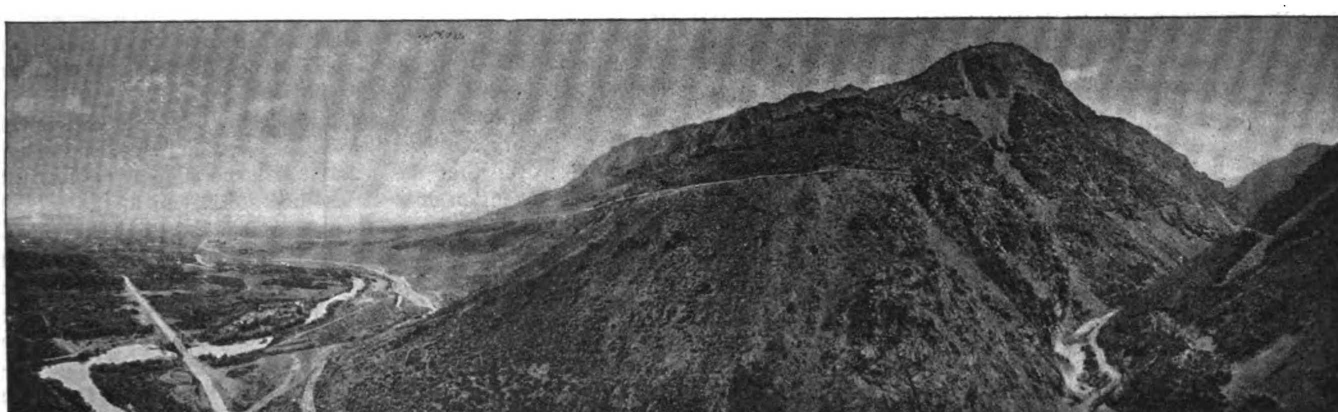
Two duplicate receivers will be used, one at each side of the power house so that either can be shut down without stopping the plant. To these the pipes running to the water wheel nozzles will be connected. The speed of the wheels will be controlled by Knight governors and the valves will be operated by hydraulic pistons so that the generators may be stopped and started from the switchboard. The water from the wheels on each side of the power house will pass into a central tail race under the floor between the two lines of generators and will be conveyed into canals for the irrigation of some 18,000 acres of land in the vicinity of Ogden, which will be reclaimed for farming purposes.

The electric plant at first will consist of five 1,000 horse-power 24-pole, three-phase generators, driven by Knight water wheels running at 300 revolutions per minute. The water wheels and fitting will be furnished by the Risdon Iron and Locomotive Works, of San Francisco. Water wheel and armature are mounted on the same shaft, and are supported by the same base frame and bearings. The periodicity of the current is 60 cycles per second and the generators will be wound for 2,300 volts. The exciters, each of 100 kilowatt capacity, direct connected to their own water wheels will be provided, either of which will suffice to excite the fields of all the generators in the completed station. The current from the generators will be carried by lead covered cables laid in ducts between the generator foundations and the wall of the building, to the generator switchboards at one end of the power house. The boards will be blue Vermont marble panels and will be completely equipped with all the necessary controlling and regulating instruments and apparatus. Tachometers on the switchboard, operated by synchronous motors electrically connected to the generators will indicate the speed of the machines.

The step-up transformers and the 2,000 and 15,000 volt feeder panels will be placed in a gallery erected over the generator switchboard. The transformers, nine in number, each of 250 kilowatt capacity, will raise the generator potential from 2,300 volts to 15,000 volts, at which pressure 2,000 horse-power will be transmitted to Salt Lake City. The local distribution of the balance at Ogden will be made at 2,300 volts.

The transmitted current will pass over six No. 1 wires strung on insulators of a special porcelain developed by the General Electric Company, to withstand high potentials, and be delivered to nine 250 kilowatt, step-down transformers at Salt Lake City, which will connect it at 2,300 volts for distribution.

The transmission line and transformers will be arranged to allow of the use of a potential of 25,000 volts. This will permit of the efficient transmission of current to the mining regions of Mercur and other camps thirty to thirty-five miles beyond Salt Lake City. All lines will be protected by the latest types of General Electric lightning arresters, which have proved so efficient in other transmissions.



FLUME FOR THE PIONEER POWER TRANSMISSION, OGDEN, UTAH.

The flume is seen passing high up across the face of the mountain and dipping to the valley on the left.

To construct the iron and wooden pipe bringing the water to the wheels, motors of 100 horse-power are set up in the shops of Rhodes Brothers, in Ogden, supplying extra power for the work which is one of the most extensive pipe line contracts ever undertaken, five miles of six-foot wooden stave pipe, and one mile of six-foot rivetted steel pipe. Practically all the work will be done on the ground, the steel being received in flat sheets to be rolled, punched and riveted in the shops, and lumber for the wooden pipe in the rough to be milled, planed and put together on the spot.

Salt Lake City, with the completion of the Pioneer plant, will receive power from two of the most important electrical transmission installations ever undertaken. That transmitting the power from the Big Cottonwood Canon, already described in The Electrical Engineer, has only recently been completed, that of the Pioneer Company will probably be inaugurated about the first of November of this year.

CONTENTS.

MOTORCYCLES.

THE details given in our last issue as to the horseless vehicle races at the Rhode Island State Fair, go to show that the contest was far better organized and far more satisfactory than any of its predecessors. This is not saying a great deal, perhaps, but as the motorcycle art has depended upon these races to show the public what could be done, it is desirable that the conditions should be of the right kind. At Chicago, last November, the race took place on soft park roads, under heavy snow and slush. In New York this year, the "race" was along crowded city streets and rough country roads and a "newly plowed golf ground," and the competitors were refused permission to traverse the firm roads of Central Park. At Providence, there was a perfect race track, off which the crowd was kept, and instead of one long race there were laid out five heats, one each day, and each of five miles. Under these circumstances, the Duryea gasoline motor which won the $3,000 prize in New York, was badly defeated, and the honors went to the two electric vehicles, one of which made its fastest mile in 2 minutes 13 seconds and the other of which made its fastest five miles in 11 minutes 27 seconds. These speeds figure out at from 25 to 30 miles an hour, a remarkable showing.

The question arises naturally as to what these races are worth, outside of arousing public attention and tickling public curiosity, and it is hard to give a reply other than condemnatory; while we find among competitors and inventors a strong feeling of distaste and a prejudice against races, in which their new vehicles are now used simply as a drawing card. Experiments and traveling are costly, and a few hundred dollars in prizes do not go very far, even if one wins. It must be this which accounts for the few entries. Each time, the entries have been small and the actual starters a disappointing fraction of the entries.

The motorcycle art is certainly advancing, but it would go ahead more quickly if the objects to be aimed at were better understood. There appear to be two classes of vehicles to be worked out, one for long distances, the other for short. In the first category the electric vehicles have no place, and it has yet to be proved that the demand is large enough to make it worthy the attention of electrical inventors. As to the second class, there is little doubt of an early demand, both for pleasure vehicles and for light business and express wagons. But it does seem as though the batteries must be lightened in some way. The weight and space of the battery equipment do not appear to be commensurate with the work to be done or the size of the motors to be driven. On a level country, lighter batteries might serve, and in a hilly locality, it might be possible to let the motors do a little generating on the down grades. But the present huge masses of battery, said to be good for 50 or 100 miles, mounted high in the air on light running gear, do not strike us as altogether the best outfit, for business purposes.

THE TELEPHOTIC PROBLEM.

SOME of the most ancient records and traditions in existence hint at the possibility of persons, separated by long distances, communicating with one another; and the speculative philosophers of the Middle Ages never tired of ringing the changes on this theme. And, indeed, at least one among them came very close to the general idea of the needle telegraph, though, of course, all essential operating detail was lacking. The telegraph, the cable and telephone have fully realized all these dreams, but in their place there has arisen another of a character designed to call forth the highest inventive faculty and mechanical precision, and that is, if we may use the expression, "seeing by wire." To convey or reproduce a picture by the well-known fac simile telegraph systems sets up relatively few difficulties, but to convey directly to the eye of the observer a picture of an object or scene at the other end of a wire is quite a different matter, involving factors entirely different from those in the fac-simile telegraph. One element, however, where but a single wire is employed in the transmission, seems to be common to both methods, and that is, synchronism in the working apparatus at both ends of the line. So far as this element of the combination is concerned the alternating synchronous motor ought to afford a rigid consonance between station and station, while Mr. Delany's synchronous telegraph apparatus will also be recalled in this connection. But how to convey the varying effects of light and shade, to say nothing of colors, is not by any means beyond the province of speculation. Naturally the peculiar properties of selenium at once suggest themselves as a medium for producing electric current effects and many ingenious ideas have been put forth based upon them. The latest addition to the list of these is the scheme of Dr. Huber, who for the first time introduces the Röntgen ray as an auxiliary at the receiving end. We do not pretend to say that the method described in another column is feasible as it stands, but as a basis for further work in this direction it may well bear study. Thus far only the one wire transmitting systems of this class have been considered, but in a recent interview Mr. Tesla is quoted as having under consideration a multiple wire system. As to the other details Mr. Tesla did not vouchsafe any information; but we hope that, having cleared the deck of other noteworthy things already in process of perfection, he may soon be in a position to give the world in practical shape, one more of the brilliant ideas that have brought him fame.

A TAME CONCLUSION.

FOR some time past, the daily press has been predicting war. We do not refer to the troubled state of affairs in Europe due to the infamous massacre of Armenians; nor to the dispute over the Venezuelan boundary; nor to the desperate condition of poor Cuba; but to the expected rivalry between the Western Union and American Bell Telephone Companies, on the expiration of their old contract in November. There have been rumors of all kinds afloat, but they ought to be laid to rest by the interview in which Mr. G. C. Hubbard has outlined the real situation. We quote the bulk of his remarks on another page; it will suffice to note here that ehe predicts peace, adding this as a clincher: "The rumor that we will enter into direct and violent competition with each other is entirely without foundation. So is the report that the Bell Company will consolidate with the Western Union. The subject has not been discussed on either side."

This last sentence is a little surprising, but no good reason is known for not accepting Mr. Hubbard's remarks as broadly true. At the same time his statement that there are 6,000 Bell stockholders, does not carry with it the implication he suggests, namely that it would be difficult for any one to buy a controlling interest and thus bring about a consolidation. There are perhaps as many shareholders to-day in Western Union, but the big blocks on either side dominate, so far as being a majority interest is concerned. A third party might step in and harmonize both by owning the controlling interests; and it is rather curious that just at this juncture it should be hinted that Mr. George Gould may sell out his Western Union Stock to Mr. Vanderbilt, while on the other hand, Mr. Morgan, always a Vanderbilt ally, has been buying Bell stock heavily, up to 25 per cent. of the total issue, it is alleged. It will be noticed that some such arrangement would not contradict a word that Mr. Hubbard has said, and would harmonize matters, while leaving each company free to manage its own affairs in its own way. All this makes it the more interesting to know what Mr. Hubbard's "secondary agreement" is likely to be. A tame conclusion anyhow is indicated, rather than a state of violent war.

THE USE OF ELECTRICITY IN THE NAVY.

WE begin in this issue the re-publication of an important and exhaustive treatise by Lieut. Bradley A. Fiske, which appears copyrighted in the "Transactions of the Naval Institute." We have obtained consent for the appearance of this article in our pages, and are glad to be able to place before our readers this latest word on a subject now occupying so much attention both here and in Europe. Lieut. Fiske, who has been attached recently to the War College at Newport, is well known as an electrical expert and inventor, while his naval duties necessarily acquaint him with many aspects of the work that are wholly unfamiliar to the layman. We are indebted to the "Transactions" and to the U. S. Office of Naval Intelligence for the cuts made specially to accompany the article.

LITERATURE.

ROENTGEN RAYS AND PHENOMENA OF THE ANODE AND CATHODE.—By E. P. Thompson and Prof. W. A. Anthony. Cloth 8 vo., 105 illus. 190 pages. New York. D. Van Nostrand Co. Price, $1.50.

This book is a striking evidence of the tremendous activity evoked by the news of the discovery made by Prof. Röntgen, but what is perhaps even more interesting is the data brought forward as to the anticipatory work without which the existence of the X-ray would not have been detected. As a digest of innumerable and often suggestive experiments, the book is invaluable. Mr. Thompson's work has been done with great industry, while the association with him of Prof. Anthony is a double assurance that the review of physical fact and theory is sound, a thing that is especially necessary in a volume that embraces so much that is still conjectural and inferential. The book is not only complete in its record, but in the illustrations that accompany the text, and the whole constitutes a work that must be in the hands of every physicist, electrician and therapeutist.

ENGINEERING CONTRACTS AND SPECIFICATIONS. By J. B. Johnson, C. E., New York, 1895. Engineering News Publishing Co. 417 pp., 6 x 9 inches.

The work is written to serve the purpose of a text book on the law of contracts and engineering specifications. The former subject is treated in a rather brief style in the early part of the book, and can serve only as a general guide to the fundamental principles of the subject. As the author states, this part of the book is intended to serve rather as a cautionary warning aganst legal entanglements than as a guide through any such difficulties. In other words, it chiefly instructs the engineer what not to do. Part II. of the book treats of the style of drawing up engineering specifications and accompanying documents; Part III., of specific descriptive or technical clauses in specifications; and Part IV. gives illustrative examples of complete contracts and specifications. In these last three parts of the book, the information given is suggestive and covers the ground under consideration perhaps as well as can be done within the limits of a single volume.

MISCELLANEOUS.

ALTERNATE CURRENT TRANSFORMERS.—VI.

BY DR. J. A. FLEMING, F. R. S.

Next, with regard to magnetic leakage, it is important to employ some test to ascertain whether there is a large magnetic leakage. Magnetic leakage, as already explained, is due to an escape of induction, linked with the primary circuit, and which does not entirely pass through the secondary. It is promoted by any separation of the primary and secondary coils, as in Fig. 44, but is not entirely eliminated by any arrangement of them, as may be seen by considering the diagrams in Fig. 45. This leakage, of course, can be ascertained by measuring the secondary drop as described above, and comparing that value with the total copper drop as calculated by the rule already given. An experimental proof of magnetic leakage can be obtained by a simple method due to Mr. Mordey. Two thermometers are taken, one filled with mercury, and the other filled with alcohol. These thermometers are compared to see that they are in agreement at the ordinary tem-

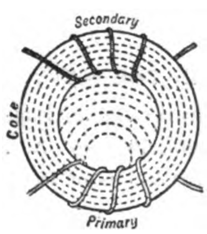

FIG. 44.

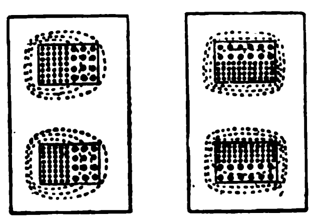

FIG. 45.

perature. The bulbs of the thermometers are then introduced into any portion of the transformer near the secondary coils and kept there for some time. If there is any leakage of magnetic induction outside the secondary circuit, this induction passing through the mercury thermometer will generate heat in the mercury and cause the mercury thermometer to rise, but the spirit thermometer will be unaffected by this process. Hence, although both thermometers will rise from external temperature, if the mercury thermometer rises more than the spirit thermometer it indicates the presence of magnetic leakage at that spot where the bulbs are placed. In some transformers magnetic leakage is actually encouraged. A transformer, designed by Elihu Thomson, intended to give constant currents from the secondary circuit when the primary circuit is worked off a constant potential circuit, is constructed as shown in Fig. 46. In this case there is a kind of iron bridge, interrupted by an air gap across the core between the primary and secondary circuit; and across this bridge, or air gap, induction is forced as the secondary current increases. This leakage, therefore, diminishes the electromotive force in the secondary circuit, and that effect tends to keep down the secondary current, and hence, to preserve it at a constant value. Such a transformer can, therefore, be employed to work arc lamps in series off a constant potential primary circuit. The secondary drop is found to be affected to some degree by the nature of the alternators on which the test was made. A peaked primary

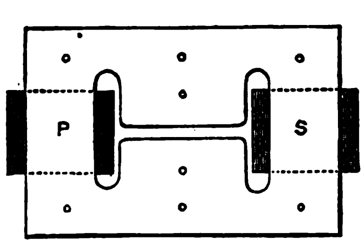

FIG. 46.—THOMSON-HOUSTON CONSTANT POTENTIAL TO CONSTANT CURRENT TRANSFORMER.

e. m. f. curve gives a greater leakage drop than one with a more rounded form. In general, however, magnetic leakage is a thing to be discouraged, and every specification for transformers ought to contain a clause defining and limiting the amount of secondary drop. One convenient way of doing this is as follows: Suppose the standard secondary electromotive force to be 100 volts, and the primary electromotive force 2,000 volts, then the specification should define that when the transformer is working on a constant potential primary circuit of 2,000 volts, the secondary terminal potential difference on the transformer should be 100 volts at half load. At full load the secondary potential difference should not be less than 98½ volts, and at no load should not be greater than 101½ volts. In this manner the unavoidable secondary drop is, as it were, distributed half up and half down, and is not so much felt on the lamps as if the transformer gave its standard electromotive force at no load, and then experienced the full effect of the drop when loaded up to full load. Also in a specification for transformers the manufacturer ought never to be allowed to produce a high efficiency at the expense of a large secondary drop, but such a definition of the core loss and copper loss ought to be given that he is bound to produce an all-round excellence. As a sort of guide to the kind of figures which may be obtained by good makers in actual practice, the following table may be taken as representing the secondary drop and core loss in transformers of these various sizes. These figures may be taken as a kind of indication of the core loss and secondary drop, which can be obtained in good modern practice in the construction of transformers. Some makers may be prepared to do better than this; but exceedingly small iron core losses ought always to be looked upon with a certain amount of suspicion, the important question being, not how low can the iron losses be made, at first, but how long will they keep low when the transformer is being used; and this, as above stated, can only be determined by careful tests, made at intervals, as the transformer ages:

Size of transformer defined by full secondary output in watts.	Allowable iron core loss on open secondary circuit in watts.	Allowable secondary drop in per cent. of normal secondary electromotive force.

ELECTRICITY IN NAVAL LIFE.—I.

BY LIEUT. B. A. FISKE, U. S. N.

$1,500,000,000 is the amount stated by The Electrical Engineer, after a careful investigation, to be the capital invested in the United States in the various electrical arts, such as the electric light, telegraph, telephone, electric railway, etc., etc. In examining the causes for the investing of so large a sum, we must conclude that either the people in the United States are a very unwise and visionary class, or else that electric appliances do really possess some qualities which contribute to their comfort and happiness in a practical way.

In examining the results of the use of electricity in naval life, we must admit that, up to the present time, electricity has fulfilled all the promises it has given us. It has made our ships brighter, cleaner and healthier; it has lightened the task of enforcing discipline; it has increased the accuracy of gunnery; it has made instruction interesting; it has assisted the surgeon in diagnosing wounds and relieving pain; it has given the captain better control of his ship, and the admiral better control of his fleet; it has added an element of intelligent interest and expectation to each new addition to our Navy, and it has brought into active sympathy with the sea-going class a large and influential body of progressive men on shore.

The enormous development of the use of electrical appliances in all countries of the civilized world, and the beneficent effects resulting, are bearing practical fruit in naval life. The experience gained by electric railway companies, electric light companies, telephone companies, telegraph companies, and all the other thousand and one branches of business in which electricity is used, has proved that electrical apparatus may be relied upon provided two conditions are fulfilled. The first condition is that the electrical apparatus shall be designed to meet the particular circumstances of each case; the second is that it shall be cared for by men who understand it. The increasing confidence shown in it by naval authorities has been particularly evident in France, where numbers of ships have been constructed in which electric power is used to do almost all the work heretofore done by auxiliary steam engines.

The principal difficulty that electricity has had to meet in our Navy has been the fact that there has been very little incentive for officers and men to study it; so that most of those who have become proficient (enlisted men as well as officers) have gone into civil life, and we find them distributed among the various colleges and electrical enterprises of the land.

There they are doing good work for the country and are making honorable reputations for themselves, but, so far as helping the Navy goes, their services are lost. So it is not surprising that electrical apparatus has come into use in the Navy so much more slowly than it has come into use in civil life; but it is surprising that it has come into use so rapidly as it has, and exhibits a more progressive spirit than seamen are usually credited with possessing.

It is frequently stated that the reason for the slow progress of electricity in naval matters is the difficulty of meeting the conditions of ship life; but this position is hardly tenable, because the conditions for the use of the electric light, electric motors and telephones in warships are in reality not nearly so severe as they are in hundreds of positions along the coasts of the country and through the long stretches of the mountainous and comparatively unpeopled sections of our western lands. In reality there can hardly be found, outside of the college laboratory, conditions which are in many respects so favorable as those to be met on board a modern warship. In the first place, the distances through which the electric current are to be transmitted are extremely short; in the second place, the item of expense does not control to so great a degree as it does in the operations of commercial life; in the third place, in case of any accident or derangement, the place where this accident or derangement occurs is always within a few feet of somebody, so that it will not have to be hunted for, as freqeuntly happens with apparatus on shore, through miles of country; in the fourth place, the solidity of the structure of a ship and the excellence of all of the mechanical appliances are in great contrast with the flimsiness of the structure and the cheap character of the installation which have, for financial reasons, in many cases to be made on shore.

About ten years ago the writer had occasion to deliver a lecture before the Franklin Institute, on Electricity in Warfare, and about four years later, another on the same subject. In the first lecture the operations of electricity in warfare were almost wholly hypothetical and promissory. In other words, the effort of the lecturer was to point out what electricity might be made to do, perhaps. In the second lecture he was able to state with some positiveness that some things could be done and, in fact, that some things had been done. In the present paper he takes pleasure in stating that certain things have actually passed official tests in sea service, and he will confine himself to facts without indulging in any flights of the imagination. To emphasize the difference between the state of affairs obtaining now and the state of affairs obtaining at the time of the first lecture, it may be said that at this first lecture there were present a commodore and a captain of the United States Navy, both officers of high ability and character, and, in a conversation after the lecture, they pointed out the impossibility of using the electric light on board ship by reason of the impracticability of getting sufficient space for the dynamo. In spite, however, of the successful efforts of the Genius of Electricity in ameliorating the conditions of shipboard life, there are still many objectors, and it is a fact that a contest is going on between electro-mechanical and other mechanical apparatus in very many of the important operations in ships and forts, which promises to be as lasting and as bitter as the contest between steam and sails; and yet it is easy to one who watches the drift of modern engineering practice to see with which the ultimate victory will reside. Just now the fight is going merrily on, and the public benefits by the competition. No sooner does an electrical device score a success than some ingenious person does the same thing with mechanics; and no sooner does an important mechanical invention accomplish some new thing than an electrician throws it altogether into the shade by a novel use of electricity. It may be stated as a general law—but with the distinct understanding that it is only general—that mechanical appliances have the advantage of greater simplicity of principle, and that electrical appliances have the advantage of greater simplicity of operation. To paraphrase this statement, mechanical appliances are more easy to understand, but electrical appliances are more easy to use. Mechanical appliances require less instruction for their use; electrical appliances render available a higher grade of intelligence and also require a higher grade of intelligence. Electrical appliances strive for an idea; mechanical appliances do what is required at the moment. The advantages of maturity and experience are on the side of mechanical apparatus; but youth and the promise of the future reside with electricity. Mechanical appliances are less apt to deteriorate from disuse; electrical appliances are less apt to deteriorate from use; mechanical connections are liable to give out under the sudden strain of emergency; electrical appliances, from their nature, suffer little strain in use and are not apt to fail in emergency if found to be in good condition before the emergency occurs. A mechanical connection, if broken or injured, gives plain sign of the whereabouts of the trouble, but the trouble is with difficulty repaired. A trouble in an electrical connection is sometimes hard to find, especially if the apparatus is not thoroughly understood, but when found, is remedied with ease. The difficulty of repairing a break or disarrangement of a mechanical appliance, caused by a stress, is usually in proportion to the greatness of the stress; but with electrical appliances, the cause of trouble is usually minute, and can be repaired as soon as found.

A very important enemy of electrical appliances on shipboard has been the "fatal facility" with which bad electrical apparatus can be installed. It has always been so easy to run a wire or to put in a battery, or a bell, or a dynamo, which would work for a week, that in very many cases it has not worked any longer. Good work on electrical apparatus often seems so unnecessary that slipshod work is substituted, and it does as well as any other for a while; but suddenly the apparatus fails, and then one hears on all sides complaints of the untrustworthiness of electricity. Nevertheless it is a fact that the naval and military uses of electricity are increasing. The same reasons that have filled modern cities with telephones, telegraph, electric motors and electric lights, are filling our modern war-ships and fortresses with them. The same reasons that gradually replaced the club of the savage with the magazine rifle of the modern soldier are operating to replace the simple but clumsy ships and battery of a few years ago with warships of tremendous power but vast complexity. It seems to be a law of nature that we must pay for what we get. If we will have monstrous engines of war, dirigible with precision and rapidity, we must use complex machinery, protest as we may.

There is one very important phase of this question to be considered, and that is, that in this feverish march of progress, one must either keep up or fall behind; and a navy must either keep up or fall behind. This state of affairs becomes more and more acute the further the march of progress proceeds; and the view may be extended even farther, so that we can see that the more complicated ships and weapons become, and the more education and instruction and drill are needed for their efficient handling, the greater advantage will rest with that navy which devotes to them the needed education, instruction and drill; provided always that the increase of power of offense and defense is sufficient. This statement may be put in another way:—In any apparatus which bestows vastly improved powers of offense or defense, mere complexity is not a disadvantage to any navy which devotes sufficient time and labor to mastering the difficulties, because the very fact of its complication gives that navy great advantage over navies which cannot or do not master the difficulties. This indicates the principal advantage of the civilized soldier over the savage. The civilized soldier is no more brave than the savage, and very often is under the greatest disadvantage by reason of lack of acclimation and of knowledge of the country. But the complicated arms and organization of the civilized forces are too much for the brain of the savage, and he is forced to retreat before the complications of civilization.

This argument is not intended to prove that complexity has of itself advantages over simplicity, because simplicity is the perfection of efficiency, as it is of beauty. It merely points out that the part of wisdom of a highly civilized nation is to develop weapons of the highest possible power, and to educate the officers and men to handle them. An hour every day taken from the merely routine work which highly educated officers of middle life are compelled to do, would show us that our profession is not only one of the most glorious in the world, but one of the most interesting, and would give us an opportunity of keeping up with the progress of the times.

In describing broadly the uses of electricity in naval life, many uses, not strictly new, must needs be included. The subject may be divided somewhat as follows:

Electric Lighting.—The electric light is now a sine qua non in modern warships. The principles previously laid down have been proved correct in practice, and the present development is along the lines of an increasing supply of lights and the gradual improvement of the details of wiring and insulation. The number of officers and men acquainted with electrical things has naturally increased, and this has brought about a better functioning of the apparatus used, as a necessary result. Searchlights of automatic feed, controllable from a distant point, have proved practicable; considerable diversity of opinion still exists as to whether they should be high above the water or low down, but the advocates of high positions are gaining ground. No important change has taken place in signal lights.

Electrically Operated Steam Whistles.—These have been recently tried in both warships and merchant ships with promising results. They do not interfere with the ordinary method of sounding the whistles, so that their use seems to confer a distinct advantage with no offsetting disadvantages.

Motors.—The use of electric motors is clearly on the increase,

especially for ventilating, the training of turrets and the hoisting of ammunition. Perhaps the advantages of electric power over steam are more obvious in the matter of ventilation than in any other field, the principal gain being in the fact that the necessity is avoided for the tremendous air ducts which take up so much room in coal bunkers and living spaces, and the substitution of a number of comparatively small ventilators, each placed where it is wanted, instead of the large steam blowers for which room is so hard to find. The military advantage of the small electric ventilator is one that may easily be overlooked; but it is a well known fact that in many ships the steam blowers have had to be placed above the water line and absolutely unprotected; which means that in the early part of an action the blower supplying one or more of the magazines may, and probably will, be put out of operation by a very insignificant cause, making it absolutely impossible for the men to remain in the magazines.

For training guns, the practice of employing motors is becoming limited to turrets, the mechanism being arranged in such a way that hand power can be used in case of accident. As regards the relative advantages of the three principal powers, steam, hydraulic and electrical, a wide diversity of opinion exists. The great desideratum of simplicity resides, of course, with steam, and many regard this feature as of paramount importance. Others, however, while admitting the superior simplicity of steam, and while admitting the enormous value of simplicity, point out the extreme difficulty of securing a "dead beat" motion with steam, even if a worm and screw be included in the mechanism. They also point out what at first sight may not seem an important point, but which may readily become so—the question of heating; insisting that, no matter what mechanism may be employed, it is after all "the man behind the gun" on whom we must rely, and that the man behind the gun and the men in the passing rooms will not work at their best in an unendurable heat.

THE TESTING DEPARTMENT OF THE GENERAL ELECTRIC CO.'S WORKS.—III.

BY THEO. STRAUS.

The record of all tests is placed on what is known as a Testing Record Sheet. On this sheet appears data such that a person, even if he had never seen the machine, could, at a glance, designate the qualities and action of the machine during the time of the test. After the test, the sheets containing only the original data are handed into the office, where they are first rigidly examined by the foreman. If correct, they are then sent to the Calculating Department for inspection and are then finally approved. If approved, the sheets are sent to the engineering department, where they are placed on file, and the machine is sent to the painting department, where it is made ready for shipment. If the test is not satisfactory the machine is re-tested. It is the policy of the company to actually perform all guarantees on the machines before shipment.

Those of special importance have their tests approved by the designing or department engineers, and the results, placed on file, can at any time be seen by the buyers or their authorized agents. Another point is strenuously adhered to during the test, that is, running the machines with the same brushes, brush-holders, fittings, etc., used after being permanently set up.

The tests given to the machines are of all characters, depending upon the guarantees required. No matter what these are, all the machines receive the company's regular commercial test. This test necessarily varies with the different types and classes of machines, but, nevertheless, the general outline is similar. The following is a description of this test, using as an example a compound wound three-phase generator:

(A) Resistances, Heat-Run and Temperatures.—The generator, before starting up for the heat-run, has its various resistances taken by the Resistance Department connected with the building. This department is fitted up with a very sensitive galvanometer connected to a standard Wheatstone bridge, and another galvanometer calibrated as a voltmeter, used in the drop method, together with a standard Weston ammeter. These have been adjusted to such a degree of accuracy, that readings are obtained within about one-half of one per cent. The department is located at the end of the building, remote from any machines or live wires, which would tend to change the standards, which might produce an error in the readings. Any part of the building can be reached, as wires, permanently stretched, run to binding posts on the various columns. The machine to be measured is connected at the nearest column, and its different resistances are taken. After each set of readings, the resistance of the line is measured and deducted, thus obtaining the true value for the resistances of the machine. Readings are always taken before and after the heat-run.

Each generator has the resistance and temperature of the following parts taken: Separate excited fields, series fields, revolving shunt, series adjustable rheostat and armature (per phase) taken. It is run continuously at a 10 per cent. overload until it assumes a permanent condition, and the temperatures have reached their maximum. Temperatures are then taken on all the accessible parts, and while the thermometers are reaching their maximum, the resistances of the various parts, as stated before, are measured. From the readings in resistance, the rise of temperature can be calculated, giving a check on those obtained from the thermometers.

The temperature by the thermometer is lower than that calculated by the rise in resistance, but the two readings are always proportional to each other. Besides this, tables have been computed from the many tests of a type and class of machines, showing the average and maximum rise in temperature of the different parts. These are also referred to, and if any temperatures rise above the maximum value an investigation is begun, and the defect remedied. At frequent intervals during the heat-run readings are taken as follows: Volts, armature; amperes, armature per line; volts, separate excited field; amperes, separate excited field; volts, across the series winding; amperes, in the series winding; speed and temperature of building. Throughout this run the machine is carefully watched and the condition of its parts such as bearings, commutator, collector rings, etc., are noted on the testing record sheet.

(B) Compounding.—Having no load on the armature and with the machine running at the proper speed, the current in the separately excited field is adjusted until the no load voltage is obtained. Readings are then taken on volts, armature; volts, field; amperes, field, and speed. Keeping the separately excited field current constant, with full load on the machine, and at proper speed, the following data are taken: Volts, armature; amperes, armature; volts, field (separate excited); amperes, field (separate excited); volts, series winding; amperes, series winding, and speed.

From the data thus secured the machine is brought up to proper full load voltage by means of the series adjustable rheostat.

All direct current machines are tested similarly, except in compounding. The ampere-turns in this case are regulated by placing a German silver shunt across the terminals of the series winding, allowing only part of the full load current to flow through the winding. Increasing or diminishing the resistance of the shunt, the machine may be compounded for any voltage. After the heat run the insulation of the various parts of the machine is tested, first, by either the galvanometer method, or the voltmeter method, using a 500-volt direct current. Then a high potential alternating current test is given. This is carried out with great care, and the slightest indication of a ground or short circuit condemns the machine, which after being repaired is re-tested.

The General Electric Company's standard for insulation resistance of their machines is one meg-ohm. Anything less than this is not passed. All machines low in insulation resistance are sent to the oven, and, if possible, baked up.

This department is the culmination point of all the material built at these works. Machines of all description are received, and, no matter how various, are sent forth after a severe and complete test, complaints being seldom thereafter received. To facilitate the following up of these machines, as they tend toward completion, test reports each day are sent to the many different departments.

ELECTRICITY FOR THE LEHIGH CANAL.

A special dispatch of September 12, from Hazleton, Pa., says: The Lehigh Coal and Navigation Company is considering the advisability of equipping the canal with electricity, which, it is claimed, will materially reduce the cost of operation. It is learned that at the last meeting of the directors Prof. Haupt, of Philadelphia, submitted figures showing the cost for such equipment. The Professor says that the Lehigh and Schuylkill Canals are well adapted for this system. His suggestions are to use the falls and dams along the canals to generate the power, and locate dynamos at such places. The estimates made by Prof. Haupt were not given out, but it is understood they show that the cost would be considerably less than animal power, which has been used. The directors have the matter now under consideration.

BALDWINSVILLE, N. Y.—The Baldwinsville Heat and Light Company has been formed with a capital stock of $20,000. The directors are: W. F. Morris, J. W. Upson, W. H. Wells, and J. T. Williams, of that place; W. H. Hoffman, of Stiles; B. Smith, of Syracuse, and J. W. Stearns.

THE ELECTRICAL ENGINEER DATA SHEETS.

SOME months ago, The Electrical Engineer began the publication of digested information in the form of Data Sheets, under the editorship of Mr. Albert B. Herrick. We now append a list of the sheets that have appeared up to date. It will be seen that Mr. Herrick, with great ability and excellent judgment, has already brought together a most interesting and valuable mass of data, which, on account of the manner in which it is printed, and the method adopted for its preservation in filing cases, has added materially to the resources of the practicing engineer. A great many branches of the electrical art have been treated, but we may say that the matter already published is but a fraction of that in hand and now being made ready. The scheme adopted proves very flexible, so that it is easy to add new sheets or replace old ones with more recent data, as occasion arises. Engineering pocketbooks are useful, but these Data Sheets have the advantage of coming up to date, and of being ceaselessly added to and expanded.

INDEX TO PUBLISHED DATA SHEETS.

TELEPHONY AND TELEGRAPHY.

BELL TELEPHONE AND WESTERN UNION.

J. Pierpont Morgan said last week that there was no truth in a published story that he was to conduct a fight for the American Bell Telephone Company against the Western Union Telegraph Company. The New York "World" insists that a fight there must be, and as a "practically official verification" of its assertion prints the following with its subjoined comment:

"There is no need of any further contract between the two companies," he said. "The contract of 1879 was made to cover certain valuable patents held by the Western Union Company, but all of these patents—except the Berliner transmitter, which is now a matter of contest—have run out, and there is nothing to hinder the telephone people from using them. The two companies will undoubtedly continue in their separate fields. The telephone company has certainly no facilities for telegraph service."

It is not expected, however, that the Bell people are going to directly antagonize the Western Union by a rival telegraph plant. It is rather by an extension of the field of telephone service. According to semi-official information, the Bell people discovered long ago that a profit could be made by the transmission by telephone and messenger of 25-word messages for 10 cents. Under the proposed system a Mr. Jones, of Wall street, could step into a convenient telephone station and write, out a message for a Mr. Smith, of Harlem. The telephone attendant would call up the station nearest to Mr. Jones' address, whisper the message to the Harlem operator, who would typewrite it and hand it to a messenger boy for delivery—an arrangement that would be much more economical and quicker than the present telegraph service. The system would, of course, apply to out-of-town messages, as the telephone wires have already pierced almost every village and hamlet in the country.

Under the present agreement the Western Union pays the American District Messenger Company two and one-half cents per message, and a similar arrangement by the telephone company would still leave a wide margin for profit.

THE TELEPHOTIC PROBLEM.—A PROPOSED SOLUTION.

BY DR. ERNST HUBER.

THE striking and puzzling problem of sending light vibrations over a wire has been attacked by many great and illustrious coryphees of technical science. This problem must not be confounded with the well-known one of telautography, by which pictures, photographs, handwriting, etc., are transmitted by electro-chemical or other means. The proposed problem is contained in the following questions:

Is it possible to transmit over one wire the images of objects in motion or at rest, from a transmitting station to a receiving station, at which receiving station the exact reproduction of said objects, in motion or at rest, may be seen by an observer? Is it possible to transmit said objects from one to the other station in such a way that, whatsoever changes in the position of said objects take place, these changes be simultaneously transmitted and may, therefore, be directly observed at the receiving station?

The present unusual prominence of this problem recalled certain efforts of mine made some years ago, the result of which, combined with the recent discoveries of Prof. Röntgen, enables me to illustrate the idea in its fundamental principles. I wish to call attention to the fact that this article is merely written to illustrate the general principles without entering into special mechanical or electro-mechanical details. I will try to present in the following lines a short, condensed description of the principles of the "telephote," or light-sender, fulfilling all the conditions of the aforesaid problem.

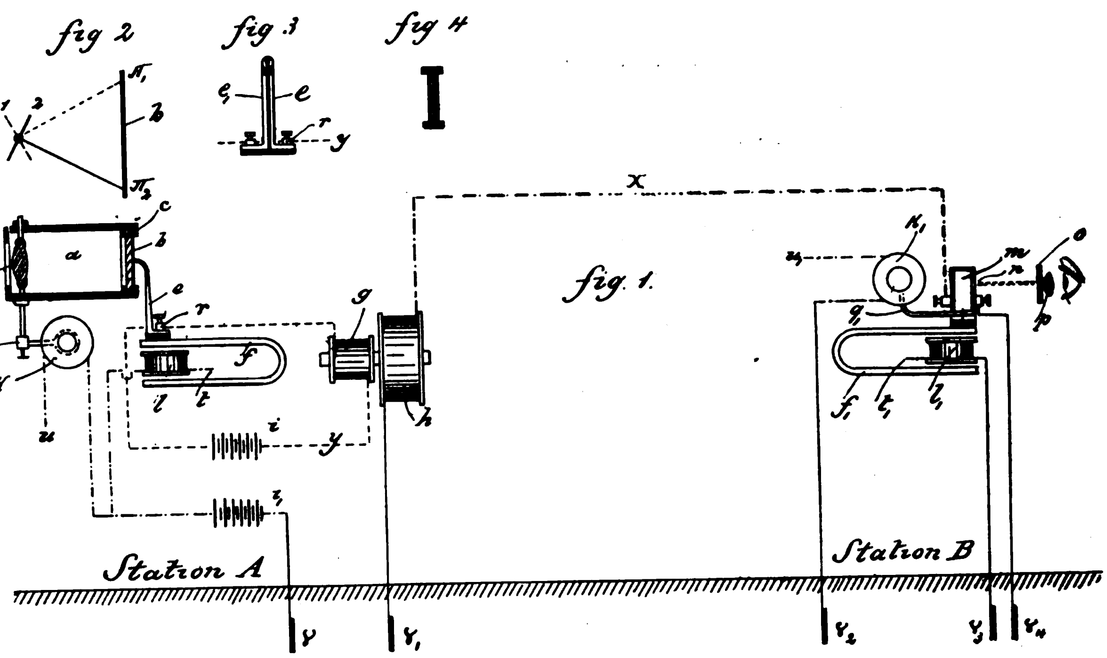
Fig. 1 is a diagram of the apparatus, showing the transmitter at station A and the receiver at station B. Fig. 2 is a diagrammatical section of the photographic lens in its extreme positions. Fig. 3 is a more detailed sketch of the connector. Fig. 4 represents a shaded letter, the picture of which is to be transmitted from station A to station B.

In Fig. 1 a represents a photographic camera provided in front with a lens d and in the rear with a thin film of selenium b, attached to and supported by a glass plate. Crystalline selenium, as is well known, has the very remarkable property of increasing its electric conductivity, when affected by light. According to the intensity of the light thrown upon the metallic film, the conductivity varies, it reaches its maximum at full light and its minimum in darkness. Prof. Bell, in his interesting radiophonic experiments, showed that the differentiation between light and dark is very considerable and that the slightest difference in illumination may be detected by combining a telephone with properly constructed selenium cells. This fact involves a variation of induction in the telephonic receiver and upon this basis the apparatus to be described is constructed.

The lens d is made to oscillate in a horizontal plane, upon a pivot by means of a polarized relay K, so that, as shown in Fig. 2, each half oscillation will carry it to its extreme positions II_1 II_2. F is a tuning fork or vibrator, the vibrations of which are sustained by means of the electro-magnet l, bearing the connector e. This connector is composed of two fine metallic springs e l, Fig. 3, bent at the top and ending there in two needle-like points in close proximity to each other. It is evident that these metallic springs are suitably insulated from each other. Electrical connection with them is established by means of binding posts r r.

The connector e rests with its top upon the selenium film b. Battery i furnishes the necessary current for the main circuit, comprising also the device g h, representing an induction apparatus, of which g is the primary and h the secondary coil. This main circuit of the transmitter runs from battery i to binding post r, spring e, selenium b, spring e, primary coil g, and back to battery. Variations of current intensity in coil g, will produce induction currents in coil h, which are sent over the main line X, to the receiver in station B.

The receiver consists of a tuning fork or vibrator f, operated by an electro-magnet in a way similar to station A. The tuning fork f, supports a Crookes tube m, enveloped with a film of material n, impermeable to X-rays. This envelop is only provided with a very fine aperture through which the rays radiate to a glass screen o, covered with a fluorescing film of barium-platino-cyanide, or calcium tungstate. The Crookes tube is mounted upon the tuning fork so that by means of lever g, it can be oscillated horizontally around its axis by means of relays K. The eye of the observer is placed before a magnifying lens. Reciprocal action between transmitter and receiver is the paramount condition of the proper functioning of the apparatus. The connector e and the Crookes tube m must oscillate synchronously with the same vertical amplitudes, and lens d and tube m must also vibrate synchronously with same horizontal amplitudes. Therefore, the respective relay and electro-magnets are mutually connected so as to establish synchronism and equal elongation.



HUBER'S SYSTEM OF TELEPHOTIC TRANSMISSION.

Suppose an object be placed before the lens d, of the camera, for instance, a letter I, as shown in Fig. 4, be painted on white paper, the picture of which we want to transmit to the receiver at station B. Lens d will project a picture of the letter upon the selenium film. It is necessary to state that this photograph must be of very small dimensions, so that the vibrations of the connector may cover the full height of the picture. It is evident that on this minute projection the black and shaded parts of the letter will affect the conductivity of the selenium. The primary circuit, being closed through the connector over the selenium surface between contact points, resting on said surface, will therefore suffer impacts in infinitely short succession, causing the secondary coil to produce the currents necessary to generate the X-rays.

As the lens d oscillates horizontally, the picture will be carried, on a horizontal line over the plate from II_1 to II_2 and back. The connector, oscillating vertically in extremely short inter-

vals, will, therefore, cover the whole area of the projection. As the Crookes tube vibrates synchronously, horizontally and vertically, and with the same amplitudes as the transmitting apparatus, an image of the same size as the original projection will appear on the fluorescing screen o, which the observer may see by means of the magnifying lens.

In order to elucidate matters I have shaded in Fig. 4 the letter I, so that one-half is entirely dark and the other half in half tone. If the connector vibrates over the dark part, very little or no current is sent over the line to station B, while, when it oscillates on the half-tone, the current will rise to an intensity adequate to the luminosity of that part. As the paper upon which the letter is painted is supposed to be white and well illuminated, it is evident that the surroundings of the letter will contrast strikingly in luminousness, and therefore all the luminous parts will, on the fluorescing screen, also contrast adequately.

As the vibrations of tuning forks and relays may be varied to any number, e. g., 500 to 30,000 per second, it is obvious that within a very small fraction of a second, the area of the reproduced image will be covered on the screen frequently enough to present to the observer a continuous and homogeneous image of the original object, with all the movements which it can possibly undergo. Thus landscapes, horse races, and like events may be seen at distances only limited by the laws of nature. It is evident, that the image produced by the X-rays on the fluorescing screen, may be projected in any suitable manner upon a large surface and thus demonstrated to a large audience.

I feel confident that the practicability and the novelty of execution of the proposed idea will not fail to prove interesting to many readers and being merely actuated by a desire to impart some new and possibly useful information to the scientific world, I conclude by welcoming suggestion and inviting discussion.

REPAIRING TELEPHONE POLES.

The tall poles of the Central New York Telephone and Telegraph Company in this city are being repaired, says the Rome (N. Y.) "Sentinel." Where the poles have decayed at the base the rotten wood is stripped off and heavy plank set in to take its place. The work is neatly done and the joints are carefully fitted so that when the job is completed and the poles repainted, as they will be, a casual observer would hardly notice that they had been patched. The idea of putting a patch on a telegraph pole, as a careful mother would reseat her boy's trousers, strikes almost everybody as a novelty and most people passing a pole where the work happens to be going on have paused involuntarily to watch it and ask questions. Telephone companies are looked upon as bloated monopolies and it seems natural to think that all they have to do when a pole decays is to pull it out and set another in its place, with a lordly disregard for the expense. The companies may have money to sink in the ocean, but they are careful in the management of their business just the same, and economy is at all times their watchword in the matter of expense. The local company is no exception and figures out exactly the cost of maintaining each mile of its line. The expenses of this division, under the supervision of Superintendent Charles N. Crain, are as low as they are anywhere in the territory controlled by the company. The cost of poles is, of course, a considerable item. The timber is pine, and the poles run from 68 to 70 feet in height and cost $25 apiece in the woods. The ones in use in Rome were set five years ago, and where they have decayed it is only on the outer shell where the sap has soaked through. The heart is as sound as it ever was. The patches are made water tight, even the nail holes being carefully puttied up, and when painted protect the wood thoroughly. Under this treatment the life of the poles is extended several years.

THE AMERICAN BELL-WESTERN UNION AGREEMENT.

In an interview in Boston, Director and Attorney Gardiner G. Hubbard, of the American Bell Telephone Company, expresses his opinion that the agreement between his company and the Western Union people will not be renewed when the existing contract expires. Mr. Hubbard says:

"We were a weak company when that agreement was formed, and the Western Union a strong one. We were gainers at first, although we have had to pay a royalty of about $400,000 or $500,000 a year for it. We will not pay a royalty in future. We needed protection, which the contract afforded then. The Western Union people have been gainers by it during the last years, however.

"The agreement has restricted us in our work. It has prevented our delivering messages, which would be considered encroaching on the field of telegraphy. We will be free from that restriction hereafter. It has been especially irksome in our short-distance transactions. What footing we will continue on I cannot say at present. It will probably be a secondary agreement to compete with each other as little as possible."

POSTAL TELEGRAPH'S NEW SOUTHERN LINE.

In consequence of the expiration of Western Union contracts the lines of telegraph on the Chesapeake Ohio and Southwestern Railroad and on the Yazoo and Mississippi Valley Railroad have been taken over, and hereafter will be operated by the Postal Telegraph Company. Both of the railroads named are in the Illinois Central system. The Western Union contracts expired on the 6th inst., and control of the lines was at once given to the Postal Company. Second Vice-President Bradley of that company states that this change will give the Postal Company a through line from Louisville to Memphis. The Chesapeake, Ohio and Southwestern telegraph lines include 1,500 miles of wire, with about fifty offices.

SUBMARINE CABLES IN WAR TIME.

Mr. James A. Scrymser, in a letter to the papers, says: "I enclose for your information an extract from a speech made by Commodore Suenson, general manager of the Northern Telegraph Company, connecting Japan and China, in London on August 14:

"'Allow me to add one more fact and one more reflection to this hurried sketch of the history of telegraphy in China. The fact is this, that although China since 1884 has been engaged in two wars with foreign powers, neither the Chinese government nor the French in 1884 and 1885, nor the Japanese in 1894 and 1895, have interfered with the telegraph cables landed on Chinese territory or with the service performed by them. They have been allowed to pursue their neutral, useful, and peaceful work to the benefit of all parties concerned, although in the last war they directly connected the two belligerent powers. This is a proof of regard for neutral property, of respect for international telegraphy, and of recognition of the immense services rendered by it, which ought to be noted, and to serve not only as an example worthy of imitation, but also as an argument in favor of the submarine companies' repeated demands for the neutrality and the inviolability of neutral cables in time of war.'

"It is to be hoped that Commodore Suenson's eloquent appeal to belligerents to respect the property of submarine cable companies will not, now that such a good example has been set us in the Far East, fall on deaf ears, but that a decision creditable to Western civilization will be arrived at."

THE CANADIAN PACIFIC CABLE.

A special dispatch from London of Sept. 12 says: The Colonial Office, responding to an inquiry as to the truth of a report in American newspapers that the Pacific Cable Commission has decided forthwith to lay the Vancouver-Australian cable, says that the report is incorrect. The Cable Commission has only affirmed the general principles of the desirability of an all British cable to Australia, and will not deliberate further on the subject until the views of Mr. Laurier, the Canadian Prime Minister, are known.

ENGLISH POSTAL TELEGRAPH FIGURES.

For the last five years the English government telegraphs have shown a deficit. This year it is less than usual and reached $175,000. There was an increase of 10 per cent. in the telegrams, the number sent being 78,839,600; of these nearly 6,000,000 were sent at press rates. The telephone system has been open to the public under post office charge since July, 1895, but no figures as to its use are given. Of the post offices 11,000 are money order and savings bank offices and 7,653 telegraph offices, but telegrams can be sent in addition from 2,273 offices at railroad stations. The year has been the most prosperous in the history of the post office, and in the history of England, but still the telegraphs did not pay.

DOG AND TELEGRAPH.

The most intelligent dog I know "resides" at Haxey, in the Isle of Axholme, and is named Staffa. Some years since, when his owner was appointed Sub-Postmaster of the village, Staffa learned to distinguish the telegraph call signal of the office in less than three weeks. I was present in the office one day, and was asking the telegraph clerk how she got on with her work, when the needle began to sound. Almost immediately Staffa came trotting in with the messenger's hat in his mouth. "Why," said the girl, "that must be our call;" and so it was.

The dog had known it before the clerk. To appreciate this fact it should be known that the call signals of two or three of the offices on the circuit are so much alike in sound that even a practiced ear may be in doubt as to which is which. Staffa, however, I was assured, never made a mistake.—"Notes and Queries."

SOCIETY AND CLUB NOTES.

INTERNATIONAL ASSOCIATION OF FIRE AND POLICE TELEGRAPH SUPERINTENDENTS.

UNDER the above somewhat copious title, the fire and police superintendents of the country have formed an organization. A meeting called on the initiative of Mr. F. C. Mason was held in Brooklyn last week, that gentleman being superintendent of the local police telegraphs; and several officials were present while others signified by letter or telegram their desire to co-operate.

W. L. Ellett, of Elmira, as chairman of the temporary Executive Committee, reported on the constitution and by-laws. They were adopted as read. The main features of the constitution and by-laws as adopted were:

"The name of the association shall be the International Association of Fire and Police Telegraph Superintendents, and its office shall be at the place where the secretary resides.

"The object of this association shall be the acquisition of experimental, statistical and scientific knowledge relating to the construction, equipment and operation of fire and police telegraphic systems, and diffusion of this knowledge among the members of this association, with the view of improving the service and reducing its cost; and the establishment and maintenance of a spirit of fraternity among the members of the association.

"The active members of this association shall consist of superintendents of fire and police telegraphic systems of the municipalities and towns of America, and other persons having charge of municipal telegraph systems.

"The association members shall consist of all others connected with said police and fire telegraph systems, and those connected with appliances relating to such systems. Associate members shall not be entitled to vote.

"The officers shall consist of a president, vice-president and five others, who shall constitute the Executive Committee; also, a secretary and treasurer.

The meeting next proceeded to the election of permanent officers. Mr. Mason was proposed as president, but he said that in view of the fact that his motives in forming the association had been questioned, he thought it were best for the interests of the association if some other gentleman was chosen, and he respectfully declined the nomination.

On motion of Mr. Smith the nominations were closed, and the secretary cast one vote, electing Mr. Mason president.

In taking the chair Mr. Mason said while he had wished some one else had been chosen, still as the association had insisted on his election, he appreciated the high honor conferred on him and considered the present as one of the happiest moments of his life, and he thanked the organization for its kindness.

Morris W. Mead, of Pittsburg, Pa., was elected vice-president; L. Lemon, of Baltimore, Md., secretary, and Adam Bosch, of Newark, treasurer.

The following were elected as permanent Executive Committee: John P. Barrett, Chicago, chairman; William C. Smith, New Haven; S. L. Wheeler, Springfield; J. F. Zeluff, Paterson, and W. Y. Ellett, Elmira.

On motion it was decided to make charter members of all those not present who had sent in their applications. It was decided that when adjourning the association should adjourn subject to the call of the Executive Commitee and that the Executive Committee should designate the city in which the next annual meeting should be held.

As an amendment to the constitution, Mr. Ellett proposed that honorary members be elected at each annual session, who should, while the session lasted, have all the privileges of membership except that of voting.

A vote of thanks was extended to Mr. Mason for his good work, and to the press for its reports of the association. The meeting then adjourned for a year.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The Institute will open its season of 1896-7 by an inaugural address from Dr. Louis Duncan, president, on the "Present Status of Power Transmission," on Wednesday, Sept. 23, at 8 p. m., at 12 West Thirty-first street.

PERSONAL.

PROFESSOR HENRI MOISSAN.

WE are glad to be able to publish this week the portrait of Prof. Henri Moissan, and to welcome the distinguished French chemist to American shores, where he is already so well known, especially among electricians, for his work with the electric furnace. He comes to represent the University of France at the celebrations at Princeton College. Prof. Moissan was born in Paris in 1852. He studied at the Faculty of Sciences and the Natural History Museum, passed an examination as a first-class pharmacist, and in 1879 became professor of practical chemistry at the Paris Superior School of Pharmacy. In 1886 he was appointed to the chair of toxicology, which he still holds. He graduated as Doctor of Sciences in 1880, and has been a member of the Academy of Medicine since 1888. The Lacaze prize was awarded to him in 1887 by the Academy of Sciences, which also in 1891 conferred on him the honor of membership. This year Prof. Moissan was one of the representatives from France at the Kelvin Jubilee at Glasgow University, and one of the recipients of the degrees conferred in honor of the occasion.

PROFESSOR HENRI MOISSAN.

In December, 1892, Prof. Moissan brought to the notice of the French Academy of Sciences his improved electrical furnace, giving a heat up to 3,000° Cent. and melting numerous oxides before regarded as irreducible. In 1893, his production of actual "diamond dust" in his furnace created a great sensation everywhere; and that work has since been followed up in various ways.

Prof. Moissan is, with the exception of M. Picard, the youngest member of the Academy of Sciences. He has a very agreeable personality, and has become widely known not only by his work but by his writings. He speaks English very well and has many acquaintances among Americans. He is accompanied on the present trip by his wife and young son.

MR. ALBERT SCHMID, the well known electrical engineer, has just returned to this country after a vacation of several months in Europe. He devoted a good deal of leisure to a careful inspection of electrical and engineering work on the other side of the Atlantic.

MARRIED.

Mr. Carlton N. Sadler, superintendent of the Orient Electric Co., of Youngstown, O., was married recently to Miss Maude Acheson, daughter of Dr. and Mrs. N. B. Acheson, of Youngstown, O

OBITUARY.

IN MEMORIAM—CHARLES E. BLIVEN.

BY W. J. JENKS.

Please permit one who knew him well to briefly record a tribute of respect to the memory of Charles E. Bliven, of Chicago, who died in Philadelphia, August 29, aged 61.

Major. Bliven was one of the old-timers in telegraph work. His army experiences with electrical apparatus contributed much to the general knowledge of electrical phenomena which enabled him in recent years to appreciate readily and clearly the proper relations between the insurance fraternity with which he was identified, and the engineers who were developing the electric light and power industry.

In 1890 he was sent, while Secretary of the Western Union Fire Underwriters' Association, to attend that important convention at Cape May, where the two interests first joined hands, through their executive officials and duly authorized representatives, for the creation of a code of electrical rules capable of ready adaptation to the necessities of the country at large. The convention was in session for two days in advance of the regular meetings of the National Electric Light Association. Major Bliven's natural leadership was at once recognized and he was made presiding officer of the council (which organized as the National Electro-Insurance Bureau), and also chairman of a codifying committee chosen by the bureau, by which committee all the then existing codes of rules were gathered and laboriously digested. The result of that patient work was the promulgation of "The National Code," which was first reported by Major Bliven to the Western Union Association at its meeting of August, 1891, at Niagara Falls, and at his recommendation adopted as the fundamental insurance law in some sixteen States. Later the code was also adopted by the National Electric Light Association; then by others, until for the past two or three years it has formed the basis of all the modifications which have been made in different States or districts of the country, to conform to local conditions. This result was apparent after two years' experience in the use of the new rules, during which time the work of the bureau was supplemented by the Underwriters' International Electric Association, of which Major Bliven was at its organization made president. His appreciation of this result appears by the following letter:

"W. J. Jenks, Esq., 44 Broad St., New York.

"Dear Sir:—With you, I have been thinking for some time past that there should be a meeting of the bureau, but I do not see my way clear to call a meeting, the members being so widely separated. I will correspond with the committee and advise you further.

"The national code of rules which was prepared by the bureau, have with very slight changes made by the International Association, been put in force in nearly all parts of the country. Yours very truly, C. E. BLIVEN, President."

It may safely be said that no more important step than the general adoption of this code was ever taken in practical demonstration of the harmony of the insurance and electrical interests, which have often been represented as radically opposed. The best methods of enforcement of the code occupied much of the thought of Major Bliven up to the time of his mental failure from overwork.

He presided at the World's Fire Insurance Congress at Chicago, in 1893, and worthily represented there the intermediate position, with reference to insurance and electrical interests, which is still occupied by Captain William Brophy, of Boston, and a few younger men, of whom F. E. Cabot and W. H. Merrill, Jr., are well known representatives.

Major Bliven's death comes as a personal loss to every reader of The Electrical Engineer, who had the good fortune to know him. Broad-minded in the best sense, conservative, tactful, well-balanced, quiet, but forcible, in all his utterances, genial and sympathetic in every relation of life, he commanded instant attention whenever he spoke by word or pen, and the respect of all who listened or read.

Mr. Bliven was born in Phelps, N. Y., Sept. 21, 1835, and when but six years of age his parents removed to Toledo, O. After having attended the public schools he entered the Ohio Wesleyan University and later the Cincinnati Law School. During much of this time he was in the telegraph service out of school hours, first as messenger and then as operator, until he finally became superintendent of the railway telegraph department of what was then the Michigan Southern and Northern Indiana Railroad. During the war he built several military telegraph lines for the Union Army, and when he retired from the service in 1866, it was with the rank of major. He was admitted about this time to the Ohio bar and practiced law for a few years.

He entered the insurance business about the time of the formation of the Fire Underwriters' Association of the Northwest, of which he was the first secretary, serving until 1876, when he was elected president. His first business connection was with the Western of Buffalo, N. Y., of which he was local and special agent. He was general agent of the Howard, N. Y., for fourteen years, and became general manager of the Western department of the American of Philadelphia in 1885.

In social life Major. Bliven was everywhere popular, and he was an active and prominent member of many of the Masonic orders, and also of the Loyal Legion, as well as of the G. A. R.

CHARLES L. CHAPIN.

Charles L. Chapin, one of the oldest telegraphers in the country, died last week in Philadelphia, at the age of sixty-six, after fifty years of continuous service in his calling. He began work as a telegrapher when sixteen years old, being selected in 1846 as operator at the Coney Island end of the second line put up between the island and Brooklyn for the maritime service. Two years before that S. F. B. Morse, who was an intimate friend of his father, Loring D. Chapin, presented to him a copy of the Morse alphabet and told him to learn it as it might some time be useful to him. In less than a year after he began work he and his associate on the Coney Island wire, Charles Robinson, were sent by the Moehrings of this city to Europe to introduce the maritime telegraph idea there. They instituted successfully a line between Hamburg and Cuxhaven, and were called then to Russia by the Czar to build a line connecting the imperial residence at St. Petersburg and the summer palace. In 1850, when Ezra Cornell established the telegraph line through this State, connecting New York with Erie, Chapin was engaged as an operator, and two years later he became superintendent of the eastern division of the New York and Erie Railroad telegraph, and from the work he accomplished there he came to be called the father of the system of running trains by means of the telegraph. He instituted the method experimentally to clear a blockade of freight trains which clogged all the switches of the single track road during a protracted snow storm. In 1854 he took charge of the police telegraph service in New York, and held the place during the police riots of Fernando Wood's troublous times and throughout the period of the draft riots. Later he became superintendent of the fire alarm telegraph, but he didn't quite suit Tweed, and in 1870 he was dismissed. From 1879 to 1887 Mr. Chapin was superintendent of the American District Telegraph in New York, and went then to Philadelphia to take charge of the telegraph and telephone system of the Bureau of Gas, continuing in that place until his death. His association with Morse he was proud of, and he treasured a letter of recommendation, dated 1853, in which the inventor commended him for any post in which a knowledge of the Morse instruments and system was required, and as his father's friend and his own wished him all success.

EDUCATIONAL.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

The prospectus for 1896-7, just issued by the Institute gives promise of a very busy and instructive season. The Department in Electricity has made arangements for lectures by Messrs J. L. Woodbridge, S. Sheldon, W. M. Hutchinson, E. J. Houston, W. C. Peckham, C. E. Emery, W. S. Barstow and G. S. Dunn. A special course of five lectures will be given by Dr. M. I. Pupin. Lectures of interest to electricians will also be given in the Departments of Engineering and Physics.

MR. J. C. GALLUP, secretary of the Correspondence School of Technology, Cleveland, writes us that the school is still growing in reputation and is gaining many students from every rank of those engaged in technical work. Courses are arranged both for beginners and for those desiring advanced study. The time taken to complete the course varies from one year for the elementary to four years for the advanced work. A system of monthly payments has been instituted for the benefit of those who find it more convenient to meet the dues in that manner.

LETTERS TO THE EDITOR.

A DEFENCE OF THE THOMSON RECORDING WATTMETER.

I THINK it not unlikely that very many of your readers may have perused with more or less interest the paper on Recording Meters, which was read by Mr. James Milne, on the occasion of the Sixth Convention of the Canadian Electrical Association, at Toronto. I have myself read this paper with much interest, and I particularly appreciate and concur in the justice which Mr. Milne has meted out to the old and reliable Edison Chemical Meter. I cannot, however, but take exception to many of the statements which he makes in referring to certain of the mechanical meters, more particularly to the Thomson recording wattmeter.

Referring to this instrument, Mr. Milne expresses some doubt as to whether it is any advantage to an illuminating company to have in service on its mains a meter which is adapted for either continuous or alternating current of any frequency without recalibration. I believe that a careful canvassing of the stations in the United States would show that this is in reality a marked advantage to almost every meter user. There is, indeed, a very large number of stations in America to-day which are distributing light both by the direct and alternating system, and generally at the same potential. To such companies the advantage of a meter which can be used indiscriminately on either system is obvious.

Not a few of these stations also supply current from their alternating mains and from their direct current mains at different periods of the day to the same users and through the same meter. This is apparently a practice which is growing in popularity, although, of course, only applicable when no motors are in use.

Again, very commonly illuminating companies which are operating both systems not uncommonly have some outlying districts which they are to-day operating, by reason of their distance from the center of distribution, by means of alternating mains and substation transformers, but which they eventually contemplate changing over to the direct current system so soon as the local business warrants so doing. In such cases as this there is surely a marked advantage in being able to make the change without the recalibration or alteration of the meter in any particular.

Not a few stations also have during the past two years found it advantageous to change the frequency of their system, and to such stations as these the ability to use the Thomson recording wattmeters, which they already had installed, without recalibrating them for the changed frequency, has been an advantage far more real than imaginary. In doubting the advantage of the universal character of the meter, therefore, the paper has, I think, run counter to the general experience of meter users.

Referring to the accuracy of the Thomson recording wattmeter upon light loads, I notice that in the paper it is associated indiscriminately with a very large class of mechanical meters, which are represented as failing to give accurate results on the light load readings. An example is cited of a 500 light meter which fails to start below five lights, and Mr. Milne complains that at this load it takes very good eyesight to note its rotation.

Without commenting on the fact that 1 per cent. of the meter's rated capacity is surely as low as anyone could expect it to record, I would call attention to the fact that the proper speed of rotation for a meter of this capacity, if absolutely accurate, would be only about one revolution in 720 seconds with a sixty watt lamp. It is not to be wondered at, therefore, that the operation of the meter should seem slow to the casual observer, even though it were recording with absolute accuracy. This very feature of the meter is undoubtedly a great merit—namely—the fact that the meter is essentially a piece of low speed apparatus, and to most of us this means without question long life; a fact that is borne out well by the behavior of the meter.

Although I do not care to enter into a discussion of the relative accuracy of the various meters upon the market, I think it can do no harm to point out that compared with results obtained by the larger illuminating companies it is quite certain that the accuracy obtainable with the Thomson recording wattmeter in commercial practice far exceeds that obtainable with the old and always reliable chemical meter, which is so ably advocated, and no where in the load curve is the relative accuracy of the two instruments so conspicuous as at the lighter loads.

This paper goes on to state, that in actual practice after a period of use it would take twelve lamps to make a 500 light meter of the Thomson recording wattmeter type record at all, and that therefore, the current to at least eight to ten lamps has no registering effects upon the meter whatever; and upon this assumption are built up some very dreadful figures, assuming that the meter will run on this light load for 3½ hours every night for five nights in the week, and coming out at the end of the figures with a net loss, which, by an unfortunate mistake of the printer is shown as 4½ per cent., but which, upon checking these figures over, we are sure must have been intended to read 3 per cent., as it figures that way.

I agree in thinking that the case cited appears to have been an aggravated case. Commonly users of any meter whatsoever, under conditions such as those described, would have taken means to prevent the running of a small number of lights for a considerable period regularly upon a very large meter. Ordinarily, I believe we reach such difficulties as this by installing the hall and office lights of theatres, etc., on a separate small capacity meter.

It is further stated, in this paper, that this same percentage of error holds good on the smaller meters. I frankly agree that the percentage of accuracy in the larger meters is as good as the percentage of accuracy in the smaller ones at the same percentage of total load, but I do not think that this brings the matter out in a new and serious light by any means; for, if a 500-light meter fails to run on 10 lights, then a 100-light meter would fail to run on two lights, and whilst it is not my experience that the average 100-light meter will behave in this manner, I nevertheless believe I am voicing the opinion of most central station men when I say that a 100 light meter is seldom, if ever, installed at a point where a load as small as two lights would be placed upon it. I am forced to believe from the strong manner in which this particular characteristic of meters is brought out, and applied more particularly to the Thomson recording wattmeter, that other standard meters have not been carefully investigated with a view to obtaining data in regard to their behavior under similar conditions.

Referring to yet another factor in central station meter operation, I quote the following: "I think I am pretty safe in stating that the motor meter has nearly outlived its usefulness as far as elevator work is concerned." This statement is based on the assumption that the recording meter in question reminds one "of a lazy man, slow to start and quick to stop."

While very reluctant to take issue on this or any other matter, I believe that I am pretty safe in stating that the one thing which the Thomson recording wattmeter will do a little better and more accurately than anything else in the way of difficult measuring, is to render a true account of the energy consumed by electric elevators. It is a fact well known to engineers that there is no more efficient means of storing power than by conserving it in a rotating disc or flywheel. In the Thomson recording wattmeter every watt of the energy which passes through its coils plays its definite part in spinning up the shaft mechanism of the meter to a definite speed, representative of the energy applied; and from the very theory of the meter it should be obvious that the reluctance of the mechanism to start forward is almost exactly offset by the continuance of rotation after the cessation of applied energy. Since, however, experiments are commonly more convincing than theory, it may do no harm to state that I have been concerned in certain experiments to determine this particular factor in connection with the meter's behavior; and these experiments were made at a time when the meter had not reached its present perfection.

They consisted in installing two meters in multiple and in series with a third meter of the same capacity as themselves. These meters were then so arranged (with a special switch) that a constant amount of energy passed through the single meter without interruption, this same energy passing through the two meters which were in multiple, sometimes half through each, sometimes all through one and sometimes all through the other, the changes in all cases being abrupt. One could scarcely conceive of a more intermittent use of current than this arrangement gave, yet the sum of the record of the two meters which measured current alternately or in multiple, agreed within less than two per cent. with the indication of the third meter through which the current flowed in constant quantity and without interruption.

Trusting that I may be pardoned for using so much of your valuable space, and offering as my excuse the fact that I am one of those who take a keen interest in the meter problem and who is not quite unfamiliar with the subject, I am, etc.,

CARYL D. HASKINS.

Boston, Sept. 4, 1896.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Dynamos and Motors:

GRAPHIC REPRESENTATION OF THE FLUX IN THE ENTREFER (AIR GAP) OF DYNAMOS.—By M. Aliamet. The value is determined by a series of measurements taken on a given scale and traced in polar co-ordinates. The method is due to M. A. Merrill.—From "L'Electricien," in Lond. "Elec. Rev.," Aug. 21, '96.

A NON-SYNCHRONOUS TWO-PHASE ALTERNATE CURRENT MOTOR.—By Ernest Wilson. An investigation of currents in armature conductors, and their effects upon the magnetic field of the motor. A detailed description of the design with many tables and curves of experimental results. The design is somewhat different from the ordinary alternating current motor in vogue.—Lond. "Elec.," Aug. 28, '96.

Electro-Chemistry:

MANUFACTURE OF CHEMICALS BY NIAGARA POWER.—By Orrin E. Dunlap. Description of the plant of the Chemical Construction Company, which has a lease for 4,000 h. p. to manufacture chlorate of potash, chlorate of soda, chlorate of barium, etc. "Elec. Eng'r." Sept. 9, '96.

ELECTROLYTIC MAGNESIUM AND ANTIMONY.—By F. Oettel. An apparatus for preparing magnesium on a small scale in the laboratory. Also commercial electro-deposited antimony described.—"Zeitschr. f. Electrochem.," 2 p. 424, p. 525; also Lond. "Elec. Rev.," Aug. 21, '96.

Lighting:

TEST OF A 300 H. P. DE LAVAL STEAM TURBINE IN THE 12TH ST., N. Y., EDISON STATION.—Three tables giving operating data of a six-hour test under conditions of full load, some tests under partial load when operated with 2, 4, 6, and 7 steam jets and temperature readings. "Elec. Eng'r." Sept. 9, '96. "Electricity." Sept. 9, '96.

ACCUMULATOR ACCESSORIES.—A dynamo with two commutators designed for small isolated plants where storage batteries are to be charged with a raised voltage. Lond. "Electricity." Aug. 14, '96.

Magnetism:

TERRESTRIAL MAGNETIC QUANTITIES.—By L. A. Bauer. Discussion on notation. "Science." Aug. 28, '96.

APPARATUS FOR TESTING MAGNETIC PERMEABILITY AND HYSTERESIS OF IRON.—Shown by Prof. Ayrton and Mr. Mather at the Royal Soc., June 10, '96. It consists of a small separately excited dynamo with a very short air space whilst the test piece forms the yoke between two massive pole pieces and is comparatively long. The whole set occupies a floor space of 22 inches by 12 inches and is 4½ inches high.—Lond. "Elec.," Aug. 28, '96.

Measurements:

TESTING DEPARTMENT OF GENERAL ELECTRIC COMPANY'S WORKS.—By Theo. Straus. The first of a series of articles deals with the testing building and the wiring in the same. "Elec. Eng'r." Sept. 9, '96.

LIGHTNING ARRESTERS.—By Wm. Baxter, Jr. After a brief statement of the actions of, and requirements for, a proper lightning arrester, author gives an illustrated description of an arrester which he designed some years ago. "Elec. Eng'r." Sept. 9, '96.

Mining:

VIRGINIUS MINES.—This power is derived from the water of the Red Canyon Creek, which is brought through a pipe line 4,000 feet long to Pelton wheels which drive G. E. bipolar dynamos. The transmission line passes first through dense timber, then over rocks and chasms and heavy snow drifts until it reaches the mine four miles away from the power house. The current is direct and the voltage 800 volts. The motors drive hoists, pumps, blowers, stamping mills, drills, and an order has recently been given for an 800-volt two-motor mining locomotive for hauling the silver-ore laden wagons in the mine. The daily expense for coal before the use of the electric plant was over $100—a ton of coal costing about $18. "Colliery Eng'r and Metal Miner." Aug., '96.

Power Transmission:

ELECTRIC TRANSMISSION FROM TIVOLI TO ROME.—Abstract of this 2,000 horse-power, 28 kilowatt transmission plant, taken from the catalogue of Ganz & Co.—"Elektrotechn. Anzeiger," Aug. 29, '96.

Railways:

LONG DISTANCE AND HEAVY DUTY ELECTRIC RAILWAYS.—By F. W. Darlington. Paper read at Altoona, Pa., before the Penn. Street Railway Assoc., Sept. 2, '96. Author dwells principally on the advantages of Electric over Steam roads. "Elec. Eng'r." Sept. 9, '96.

STREET RAILWAY CONVENTION OF N. Y. STATE.—A complete list of the papers presented.—"Elec. Age," Aug. 29, '96.

Roentgen Rays:

PRACTICABILITY OF THE STATIC MACHINE FOR X-RAY WORK.—A new type of Topler-Holtz machine is illustrated and described. "Elec. Eng'r." Sept. 9, '96.

APPLICATION OF ROENTGEN RAYS.—A few excellent pictures apparently reproduced from Dr. Morton's forthcoming book on the subject.—"Elec. Age," Aug. 29, '96.

A NEW TUBE.—By M. Kundson. A tube with a very heavy cathode which tends to dissipate the heat generated.—"Chemiker Zeit.," Aug. 22, '96.

Telephony, Telegraphy, etc:

CABLE LAYING ON THE AMAZON RIVER.—By Alexander Siemens. Abstract of paper read before the Royal Soc. of Great Britain. Conditions and incidents during the progress of the work. "Elec. Doings." Sept., '96.

Wiring:

MANUFACTURE OF WIRE.—By F. A. C. Perrine, D. Sc. Author treats galvanization, stranding of copper wires, gauging, wire gauges. "Elec. Eng'ing." Sept., '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED SEPT. 8, 1896.

Alarms and Signals:—

PROTECTIVE SYSTEM FOR BUILDINGS. C. Burgher, Newton, Mass., 567,577. Filed Nov. 23, 1895.
Details of construction.

RAILWAY CROSSING SIGNAL. C. Selden, Baltimore, Md., 567,753. Filed April 21, 1896.
Details of construction.

ELECTRIC SIGNAL. C. P. Wilkinson, Jackson, Mich., 567,759. Filed Dec. 7, 1895.
A lever having a head at the lower end set at an oblique angle edgewise to the wire and trolley wheel, so that the wheel will have a shearing contact with the head.

ELECTRIC TRACK SIGNAL. C. P. Wilkinson, Jackson, Mich., 567,760. Filed Dec. 12, 1895.
Similar to above.

BURGLAR ALARM. W. H. Ward, Mound City, Kan., 567,845. Filed June 23, 1896.
A contact is made by means of a movable floor arranged above the vault floor.

Batteries:—

MOLD FOR BATTERY PLATES. C. G. Fawkes, Denver, Colo., 567,705. Filed Aug. 7, 1895.
Leaves constructed with counter-sunk portions on the inner faces, and provided with separated lugs arranged in line to form openings in the sides of the battery plates, combined with a removable core, the parts of which are slotted so as to allow the separated lugs on the two leaves to meet through the slot.

METHOD OF PRODUCING ELECTRICITY. J. R. Payson, Jr., Chicago, Ill., 567,721. Filed Feb. 24, 1896.
The electrolyte surrounding the positive electrode contains sulphuretted hydrogen and ammonia; air is supplied to the negative electrode.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. G. E. Dorman, Chicago, Ill., 567,586. Filed Feb. 4, 1896.
Comprises a base provided with an upwardly projecting pole-piece, a second pole-piece opposite first pole-piece and consisting of two or more independent sections, independently connected with the lower portion.

AUTOMATIC REGULATOR FOR ELECTRIC MOTORS. H. P. Merriam, New York, 567,651. Filed April 28, 1896.
Comprises a variable resistance, a switch and means of cutting out the resistance operated by an increase of pressure in the operated mechanism.

DYNAMO ELECTRIC MACHINE. H. W. Libbey, Boston, Mass., 567,719. Filed Sept. 16, 1895.

Particularly adapted for generating electricity for headlights for bicycles.

COMMUTATOR. F. J. Haerer and C. L. Gikeleiter, Philadelphia, Pa., 567,745. Filed April 11, 1896.

Comprises a plurality of half discs, having recesses near their periphery, means for holding said discs in assembled position and filling piece for recesses.

ARMATURE FOR DYNAMO ELECTRIC MACHINES. F. J. Haerer and C. L. Gikeleiter, Philadelphia, Pa., 567,746. Filed April 11, 1896.

Comprises a plurality of coils or windings which are supported upon heads, clamps mounted upon heads and adapted to lock the coils in position and means for securing the clamps to the heads.

Electro-Metallurgy:—

PROCESS OF TINNING OR GALVANIZING METALS. A. S. Ramage, Cleveland, O., 567,612. Filed Nov. 4, 1895.

Consists in subjecting iron plates to a bath containing salts of iron and sodium or ammonium salts making the iron the anode in the process of electrolysis whereby the scale is removed and the pure iron contained therein deposited upon the cathode, then reversing the polarity of the electrodes and re-depositing the pure iron.

ELECTRIC SMELTING FURNACE. J. A. Vincent, Philadelphia, Pa., 567,699. Filed Oct. 30, 1895.

In combination a vertical hearth, lateral acting electrodes and a movable bottom which recedes as the melted product increases within the hearth.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. P. R. Salberg, Allegheny, Pa., 567,691. Filed Jan. 11, 1896.

Feed mechanism.

ELECTRIC ARC LAMP. J. McLaughlin, Chicago, Ill., 567,840. Filed March 4, 1895.

Details of construction.

Miscellaneous:—

ELECTROMAGNET PIN-EXTRACTOR ATTACHMENT FOR CLOTH FINISHING MACHINES. A. C. Shuttleworth, Philadelphia, Pa., 567,619. Filed Nov. 12, 1895.

The combination of a supporting framework, and an electromagnet having extending poles relatively associated and constructed to overlap each other.

PROCESS OF PRODUCING AND COATING PATTERNS. W. P. Smith, Albany, N. Y., 567,694. Filed April 28, 1896.

Consists in coating a non-conducting substance, such as hard rubber by depositing metallic nickel upon the surface.

DIAPHRAGM CLAMP FOR PHONOGRAPHS. V. H. Emerson, Newark, N. J., 567,738. Filed Dec. 20, 1895.

ELECTRICAL CONDENSER. N. Tesla, New York, 567,818. Filed June 17, 1896.

Provided with means for the exclusion of air and gas, and an armature composed of a conducting liquid.

CONTACT DEVICE. F. W. N. E. Hayn, Bahia, Brazil, 567,899. Filed May 14, 1896.

Embodies an aluminum contact bar.

INTERCHANGEABLE ELECTRIC SIGN. W. J. Scott and H. W. Shonnard, New York, 567,924. Filed May 22, 1896.

Consists in the construction of a reservoir for holding the letters and delivering them to and receiving them from the visual sign board.

IGNITING DEVICE. H. Van Hoevenbergh, New York, 567,928. Filed July 1, 1896.

Comprises a plurality of fine conductors supported in contact with one another at a number of points.

Railways and Appliances:—

STREET ANNUNCIATOR. H. P. Frear, San Francisco, Cal., 567,643. Filed Nov. 13, 1895.

Consists of a revolvable drum provided with a series of hinged tablets, a chamber within the drum's contour containing an electromagnet, armature and pawl, by means of which the drum is revolved.

ELECTRIC LOCOMOTIVE. S. H. Short, Cleveland, O., 567,662. Filed Sept. 3, 1895.

Embodies a vertically swinging frame in which the motor is mounted.

TROLLEY CATCHER. O. R. Sackett, Niagara Falls, N. Y., 567,690. Filed May 16, 1896.

A supporting frame pivoted at its upper end to the trolley pole so as to be capable of reversal thereon, a spring drum journaled in frame, and a rope or cord wound upon the drum.

TROLLEY CONTACT DEVICE. R. Skeen, Madison, Ill., 567,754. Filed Sept. 19, 1895.

Comprises a supporting bar adapted to be insulatingly mounted above the trolley wire and having depending plate fingers adapted to contact with the trolley groove as the trolley passes along the adjacent wire.

INSULATED CROSSOVER FOR TROLLEY WIRES. A. Hanson, Chicago, Ill., 567,784. Filed April 3, 1896.

Details of construction.

ELECTRIC CONTACT DEVICE. R. Skeen, Madison, Ill., 567,816. Filed Feb. 17, 1896.

Comprises a laterally movable piece insulatingly mounted above the trolley wire, its lower edge lying in the path of the trolley, a guard strip along one side of the lower edge of said piece, and insulating material between the guard strip and the piece.

BOND FOR ELECTRIC RAILWAYS. J. McLaughlin, Chicago, Ill., 567,841. Filed April 13, 1896.

Consists of a conductor, a bushing and a self-locking key.

TROLLEY GUARD. F. S. Birth, Philadelphia, Pa., 567,879. Filed Nov. 19, 1895.

Comprises a primary trolley wheel, a rock arm pivoted to the trolley arm, two secondary trolley wheels journaled in the rock arm and springs for retaining the rock arm in a normal position.

Regulation:

REGULATING ADMISSION OF CURRENT TO MOTORS. F. E. Herdman, Winnetka, Ill., 567,714. Filed Dec. 21, 1895.

The field is controlled by a centrifugal governor.

Switches, Cut-Outs, Etc:

ELECTRIC CUT-OUT AND ANNUNCIATOR. J. Kips, New York, 567,599. Filed Feb. 11, 1896.

Embodies the use of a thermostat.

AUTOMATIC CUT-OUT. H. F. Parshall, London, England, 567,608. Filed July 18, 1896.

Adapted for dynamo electric machines.

Telephones:—

TELEPHONE. R. F. Rankin, Philadelphia, Pa., 567,688. Filed Oct. 22, 1895.

Employs a rolling electrode adapted to close the circuit.

TELEPHONE SWITCH. E. E. Ries, Baltimore, Md., 567,794. Filed June 26, 1896.

Details of construction.

LEGAL NOTES.

ANOTHER TROLLEY BASE ORDER MODIFIED.—THE SIMONDS MFG. CO. ALLOWED TO MANUFACTURE.

Last March the U. S. Circuit Court for the Western District of Pennsylvania granted an injunction against the Simonds Manufacturing Company, of Pittsburg, preventing them from manufacturing and selling trolley bases and parts. This order was modified by the same court on Sept. 8, as follows:

"It is not intended by the above order (meaning the injunction order granted March 18, 1896), to enjoin the defendants against the sale of trolley stands, or trolley wheels, or trolley harps, by way of replacing such individual parts in car equipments, embodying the patented combinations, which may have been previously sold by the complainant to purchasers, in cases where such parts have been broken, worn out by use, or are otherwise inefficient, but this permission does not give authority to reconstruct or rebuild a combination which has been sold by the complainant."

We understand that the Simonds Company is now prepared to supply trolley bases, harps, wheels and all parts of the combination to authorized companies.

RIGHT TO LAY ELECTRIC CONDUCTORS.

The right to lay electric light wires in the streets of a city by virtue of a franchise to lay pipes, fixtures or other things for the purpose of lighting the city, is held, in State ex. rel. Laclede Gas Light Company vs. Murphy (Mo.), 31 L. R. A., 798, to be subject to the municipal control of the streets and general police power regulating and restricting the manner in which such wires, tubes and cables may be secured and supported and insulated, especially when the franchise was given before the use of electricity for such purpose was known. The annotation to this case reviews the authorities on police regulations of electric companies.

MAINE RAILROAD COMMISSIONERS REFUSE AN ELECTRIC RAILROAD APPLICATION.

The Railroad Commissioners of Maine, Joseph B. Peaks, Benjamin F. Chadbourne and Frederic Danforth, after a hearing, have refused to grant a certificate that public convenience requires an electric railroad on the highway between Westbrook and Gorham. The application was made by the Portland Extension Railroad Company, and it was argued that, the language of the statute being general, the interpretation of it by the Commissioners should be liberal. The petition was opposed by the Portland & Rochester Railroad, whose track would be paralleled by the proposed new line. The commissioners found no compulsion to exist in the law, and no conditions proved as to need and convenience.

FINANCIAL.

CHICAGO EDISON CO.

In view of the great cheapness of money, President Insull, of the Chicago Edison Company, has for some time past been engaged in work looking to the refunding of its obligations on a better basis, the securities of the company having been issued at a time when the market for such electric lighting bonds exacted a much higher rate. A special dispatch of Sept. 16 from Chicago says: The largest trust deed ever recorded in this county was filed to-day. The deed was by the Chicago Edison Company to the Merchants' Loan and Trust Company, and was for $3,500,000. It is to secure an issue of bonds of that amount. The mortgage is on all the property, real and personal, of the company. The document is dated July 1, 1896.

At the annual meeting of the stockholders in June last the company was authorized to issue bonds to the amount of $3,500,000, with a further issue in the future of $2,500,000, if necessary. The object of the present issue is to refund the present indebtedness of the company.

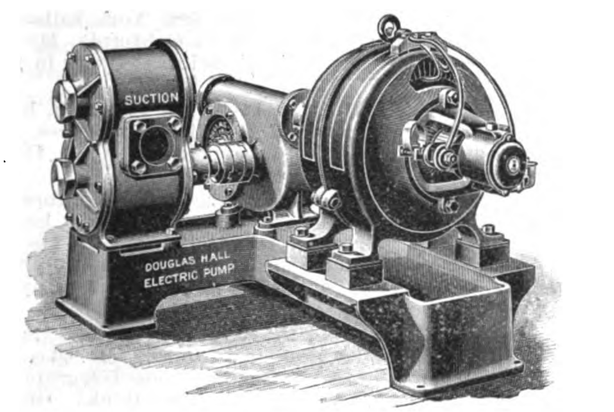
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

DOUGLASS-HALL ELECTRIC PUMP.

THE electric pumping combination we illustrate has been designed particularly for maintaining a supply of water for house purposes, operating hydraulic elevators or for any service where it is desired to elevate or distribute water. Its manufacturers were among the first to adapt the pump to the electric motor, and the present combination represents the result of an extended experience in this line of work.

Any form of electric motor can be used with the pump, that shown in the illustration being of the Lundell type. To the shaft of the motor armature is direct-coupled a two-part worm, one helix being right, and the other left handed. These mesh with two gears, to one of which the pump shaft makes fast. By means of this double worm gearing, end thrust of the worm is entirely obviated. The pump is of the rotary gear type, the action being similar in principle to that of the well-known Root blower. There are two wide gears each having 12



DOUGLASS-HALL ELECTRIC PUMP

deep teeth, the driving gear being of brass and the other one of hard rubber. This, it may be remarked, is one of the oldest types of water pumps, its invention dating from the sixteenth century. In its original form a serious objection was encountered from friction and constant wear, due to the reaction of the discharge pressure. In the present type this pressure is balanced by means of ports or radial openings between each tooth and extending through the gears, the discharge pressure being thus made to act on both sides of the gears, thereby perfectly balancing them. Owing to this ingenious method, the gears are subject to no grinding wear against the suction side of the gear case, and the bearings will run true indefinitely.

The pumping outfit includes an automatic starting rheostat operated by an electrical device at the receiving water tank. The pump described is the invention of Mr. M. W. Hall, and is manufactured by the W. & B. Douglass Co., 87 John street, New York.

THE ARMINGTON & SIMS ENGINE CO.

It will be a matter of great pleasure and satisfaction to a great many people in the electrical field to learn that the Armington & Sims Co., whose suspension was recently threatened by the sudden death of Mr. Henry C. Cranston, the Providence banker, is in excellent shape again to prosecute its business. The financial entanglement of the affairs of the company with those of Mr. Cranston, was most embarrassing, but the officers of the corporation met the situation bravely and promptly by placing the concern at once in the hands of the creditors. An influential committee was chosen, which called in three experts. After a most rigorous examination of the books, and a scaling down ruthlessly of all accounts receivable, the condition of the company was found so favorable, that it was at once voted to continue the operation of the works. The chairman of the Banking Committee, which took this step, was Mr. Marsden J. Perry, president of the Narragansett Electric Light Company, and ex-president of the National Electric Light Association, and it is understood that he will hereafter give a share of his time to the company, a fact that must be regarded as very fortunate, his knowledge of the engine industry and of the lighting business being unusually close and exact. It is a sign of the confidence of the committee that by judicious handling, the company can be carried on with wonted success and prosperity.

It is needless to say that all old orders are to be filled and that new orders are being received in the regular way. The high standard of excellence that has made the Armington & Sims engines famous all over the world will be rigidly maintained, and even raised as opportunity offers and requires. We are glad to learn that the working force has already been increased, and that the demand for Armington & Sims engines is manifesting a briskness which a favorable result to the November elections can but intensify and confirm. It is but fitting to extend to Mr. G. C. Sims, upon whom has fallen the brunt of the recent sudden and severe ordeal, at a time of trade depression when it was hardest to resist, the congratulations of the electrical fraternity among whom he has so many good friends and sincere admirers of long standing.

LOCKE INSULATORS ON HIGH TENSION CIRCUITS.

In our issue of last week we published an interesting article on the Nevada County Electric Power Company, in which mention was made of the pole line, carrying triple petticoat porcelain insulators. We have since learned that this excellent material is furnished by Mr. Fred M. Locke, whose porcelain and glass insulators and steel insulating pins have met with considerable favor in different parts of the country in construction work, and especially for high tension circuits for light and power.

INTERIOR CONDUIT FOR CHICAGO CAVE DWELLERS.

One of the most unique buildings in Chicago will be the banking house now being constructed for the Illinois Trust and Savings Bank. In that city of wonderful sky-scrapers, this building will nestle down with only two stories to its foundation, as the owners have determined to restrict the edifice to the sole use of the bank. Mr. D. H. Burnham is the architect, and it is safe to say that no financial institution in the world will have a building more perfectly appointed for their special needs or more beautiful in artistic design and proportion. This will be one of the notable buildings in the great Western City. The Central Electric Company advise us that it will have one of the most complete electric lighting plants in the city. All the wire will be inducted through iron armored conduit. This will insure absolute protection to the wire so long as the building stands and who can say that it may not endure for a thousand years?

LONG-BURNING ARC LAMPS.

The General Electric Company have recently issued an illustrated brochure on their 100-hour and 150-hour long-burning arc lamps for use on direct current incandescent circuits. The figures given show a remarkable saving in the cost of carbon renewals.

Taking four hours as the average daily run throughout the year on commercial circuits, a lamp which gives 150 hours continuous service will need trimming but eight times per year. As this lamp requires only one new carbon at each trimming, the cost of renewing the carbons will be only twenty cents per year, using the high grade carbons at $25 per thousand.

Ordinary constant potential arc lamps burning the same number of hours will require 150 renewals of carbons, using two carbons at each trimming. At $18 per thousand these would cost $5.40 per lamp per year. The following statement shows the difference in the expense of carbons alone in a plant operating 100 lamps:

Operating 100 ordinary arc lamps, carbons cost per year	$540.00
Operating 100 long burning lamps, carbons cost per year	20.00
A difference in expense per year of carbons alone of	$520.00

Both the 100 hour and the 150 hour lamps are used on 110 volt circuits. A self contained resistance in each lamp lowers the potential at the arc to between 76 and 80 volts. The current used is 5 amperes.

SOUTHERN NOTES.

JOHN WEDDERBURN & COMPANY, the enterprising patent attorneys, Washington, D. C., offered in their series of monthly competitions a prize for the best campaign button. The prize of $150 has been awarded to Mr. S. R. Ireland, of Ashland, Ky., for a "Daisy" free silver button, the center being gold and the white petals around it numbering 16, to signify the obsolete ratio that the Popocrats tie themselves to.

MR. PAUL WINSOR, the treasurer and general manager of the Southern Electric Company, Hoen Building, Baltimore, writes us that his company has just taken over the Morrison Southern Electric Company. The new concern will be in much better condition financially than the old one, and it is expected that things will move very smoothly and prosperously.

LAKE CITY, FLA., is now lighted by electricity, using arcs of 2,000 candle-power and incandescents of 32 candle-power. The plant has been put in by Mr. W. R. Bush, of the Lake City Water and Light Company, assisted by Messrs. Lucius Fielder, E. O. Powers and N. H. Cox. Mr. Powers, who is the electrician of the plant, filled a like capacity at the Ponce de Leon Hotel, at St. Augustine, last winter.

MR. SIMON LAKE, a machinist, and connected with the Lake Submarine Company, is having built at the Malster Shipyards, Baltimore, an electric boat which is intended to assist in wreckage operations. It is to be propelled by steam on the surface, and by storage batteries below.

PHILADELPHIA NOTES.

THE PNEUMATIC TELEPHONE ATTACHMENT COMPANY have filed articles of incorporation at Camden, N. J. The incorporators are E. C. and S. G. Hess, of Camden; C. F. Hess, of Philadelphia, and G. Wells, of Wilmington, Del. The capital stock is $50,000; amount paid in $100.

WESTERN NOTES.

THE WISCONSIN TELEPHONE COMPANY is building a west side exchange at Milwaukee.

THE BELL TELEPHONE COMPANY, of Cincinnati, is building a warehouse and stables to cost $20,000.

THE FORT WAYNE ELECTRIC CORPORATION have been awarded the contract for the electrocution apparatus at the Columbus (Ohio), Penitentiary, at the price of $1,515.

THE BRUSH FACTORY.—A rumor is current in Cleveland and Lynn that the factory of the Brush Electric Company is to be removed to the latter place. No confirmation of the report is obtainable so far.

THE FRASER ELECTRIC ELEVATOR COMPANY has been formed in San Francisco, with a capital stock of $100,000, by E. M. Fraser, G. Crocker, C. E. Green, J. J. Mahon, and A. J. McNicoll.

SONORA, CAL.—The owners of the electric power and lighting plant at Sonora, Tuolumne County, Messrs. Crooks & Jarboe, propose to expend $50,000 in improving the plant and have decided to furnish the power needed direct from the river.

ARMORITE is forging ahead, and rapidly becoming known as a standard for interior conduit work. The Electric Appliance Company are more than pleased with the success of their new specialty, and have increased their stock to supply all demands.

STAUNTON, ILL.—The city council of Staunton will receive bids on Sept. 29 for a municipal lighting plant. Further information on the subject can be obtained from the city clerk or from Bryan & Humphrey, the consulting engineers, Turner building, St. Louis, Mo.

MEXICO.—Orders have been placed with the Westinghouse Electric Company, Pittsburg, and Ball Engine Company, Erie, Pa., by an electric light company at Jalapa, Mexico, for a 350 horse-power tandem compound engine, direct connected to a Westinghouse alternating machine.

MR. ALBERT SCHEIBLE, of Chicago, has been a welcome visitor in the East, where his thoughtful, useful articles on practical electrical topics of the hour have made him many friends. He is on vacation and taking a long rest before he plunges again into the activities of the West.

THE NATIONAL TUBE WORKS, McKeesport, Pa., recently ordered from the Ball Engine Company, Erie, Pa., through their Pittsburg representatives, F. R. Dravo & Co., a 250-horse-power engine to be direct connected to Crocker-Wheeler generator. The combination will be used for power transmission.

BUNKER HILL, ILL.—The Bunker Hill Foundry and Machine Works have put in an electric light plant, with a capital of $25,000, to do local lighting. They have bought a 375-light dynamo from the Colburn Electric Manufacturing Company and have a 45-horse-power engine and boiler. There is about half a mile of circuit.

MR. CHAS. S. BARKELEW, of Middletown, O., has been compelled to purchase some improved machinery for his plant, which has considerably increased his facilities for manufacture. Sales of his dynamo brush have more than doubled during the past two months, which is the best evidence of the entire satisfaction they are giving; and a number of his sales have been to some of the largest central stations in the country. The successful central station managers to-day are those who wish to practice economy in the conduct of their stations, and to such Mr. Barkelew's brushes particularly appeal.

THE CENTRAL ELECTRIC COMPANY, 173-175 Adams street, Chicago, are making active arrangements for a heavy fall business. They do not seem to be devoting very much time to worrying over the financial question, but are "after orders." The country needs light and if it doesn't "see daylight" in November, why, it will take that much more incandescent light to get along. In the "Central's" estimation, the best way to get that is to use Pharos lamps and Wagner transformers, two of their well known specialties. They report a good trade in house goods material. Their Extra B. B. iron box bell has been a revelation to electric bell fitters, as showing how much excellence and good workmanship can be bought for such a small fraction of a dollar.

NEW YORK NOTES.

MR. H. C. TOWNSEND, the patent expert, has just returned home after a prolonged stay in Europe, where he has engaged all summer on some important patent work.

MR. JOHN VAN VLECK, of the New York Edison Company, has been taking his vacation in California. Mr. Frank Van Vleck, his brother, is also an electrical engineer in practice at Los Angeles.

THE AJAX ELECTRIC COMPANY, of Brooklyn, has been formed for the manufacture of electrical appliances, with a capital stock of $50,000. The directors are T. C. P. Horsfield, A. S. Willdig and W. D. Spelman.

MR. J. E. BRIGGS, secretary of the Syracuse Storage Battery Company, was a welcome visitor to New York last week, in connection with important prospective work. He reports closing a contract with the police alarm service of Buffalo for 850 cells of Syracuse battery. This is but one of many recent large orders.

THE FOLLOWING from the New York "Times" may be a "flyer" or it may be something else: Suppose Mr. Geo. J. Gould should sell out his interest in Western Union Telegraph to Mr. W. K. Vanderbilt—what would Wall street think? Once upon a time the Vanderbilts owned Western Union, and it may not be overstrange that one of the family should be willing to take up the property again."

THE SMITH INVESTIGATION has been dragging itself along and several witnesses have been put on the stand, some on the one side to prove that the fire alarm service was excellent and unsurpassed under Supt. Smith's management, and others, on the other side, to prove that the specifications for cable, etc., were so framed that nobody could bid on them with a chance of getting the order, except the Standard Underground Cable Company.

THE GENERAL ELECTRIC COMPANY intends to take an active part in the coming convention of the Street Railway Association at St. Louis. It has engaged a large exhibit space in the Convention Hall, to the left of the main entrance, and will make its headquarters at the Southern Hotel. The major part of its exhibit will be given over to the latest devices for street railway practice. The literature will be of the plain useful kind. The company will be represented by a staff of its best known railway men. Its headquarters at the Southern will occupy the large parlors facing the dining room, and here a hearty welcome will be extended to visitors.

ADVERTISERS' HINTS.

THE C & C ELECTRIC COMPANY address a letter to the trade which is worthy of careful perusal.

DE VEAU & CO. are pleased to send their price lists to possible purchasers of telephones for all service.

THE BERLIN IRON BRIDGE COMPANY make a specialty of fireproof shutters and doors, which have stood some very flattering tests.

THE SILVER AGITATION and its bearing on the use of Electra carbons makes the "ad." of the Electric Appliance Company interesting.

THE SIEMENS & HALSKE ELECTRIC COMPANY invite the attention of purchasers to their generators, lamps, mining locomotives, trolleys, etc.

PLATES OF MICANITE for commutator segments, or stamped to any desired shape may be obtained of the Mica Insulator Company, New York, Chicago and London.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. SEPTEMBER 30, 1896. No. 439.

MISCELLANEOUS.

PROTECTION AGAINST LIGHTNING FOR HIGH POTENTIAL POWER TRANSMISSION CIRCUITS.

BY A. J. WURTS.

POWER transmission circuits do not require line arresters. The points of protection being at the extremities of the system, namely, the power house and motor stations, a group of non-arcing metal lightning arresters, in combination with choke coils, is installed at each of these points. Such a group

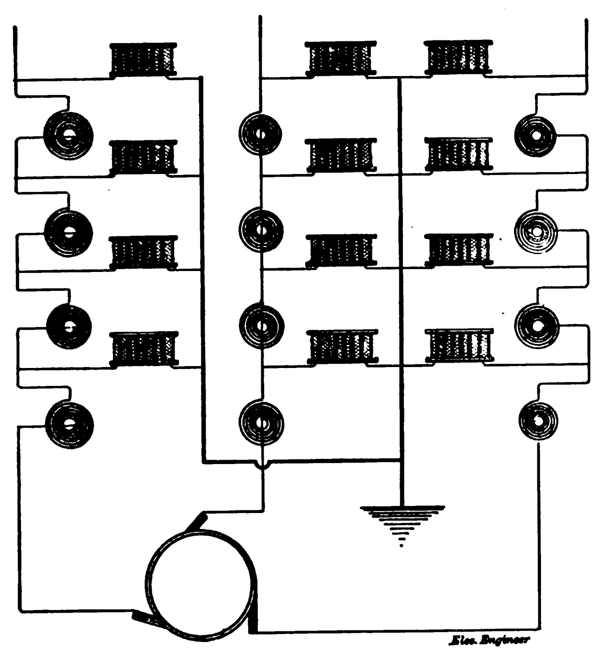


FIG. 1.—CONNECTION FOR 2,000 VOLTS 3-WIRE SYSTEM.

is diagrammatically illustrated in Fig. 1, which represents one end of a 2,000 volt 3-wire system.

To effectively protect circuits carrying potentials of 10,000 or 15,000 volts, it is necessary to use a considerable number of choke coils and lightning arresters. The fact that where these high potentials are used the circuits are usually of great length and especially exposed to the effects of lightning, emphasizes the importance of ample protection. The proper installation of the necessary apparatus has heretofore required a considerable space, and this has led to a more simple combination of choke coils and arresters, called, for reasons that

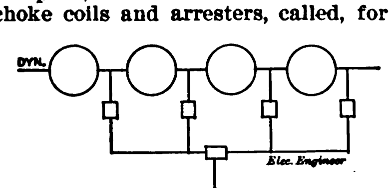

FIG. 2.—CONNECTION FOR 3,000 VOLTS.

will be evident upon inspection of the diagrams Figs. 2 to 6 inclusive, the pyramidal form. This reduces the number of arresters required for the very high potential circuits, without making the protection secured in any degree less effective.

To economize space and facilitate the proper mounting and connections of the apparatus, a rack has been designeu which is illustrated in Figs. 7 and 8.

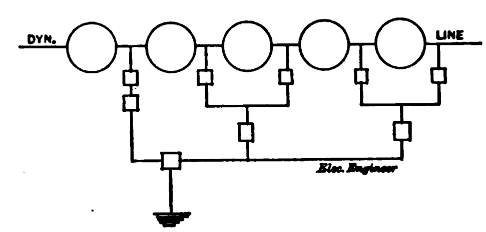

FIG. 3. CONNECTION FOR 5,000 VOLTS.

Figs. 2 to 6 illustrate the pyramidal form of connecting the non-arcing metal arresters for 3,000, 5,000, 8,000, 10,000 and

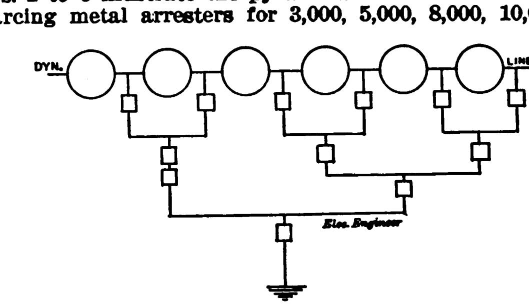

FIG. 4.—CONNECTION FOR 8,000 VOLTS.

15,000 volt circuits, the circles representing choke coils and the rectangles non-arcing metal lightning arresters.

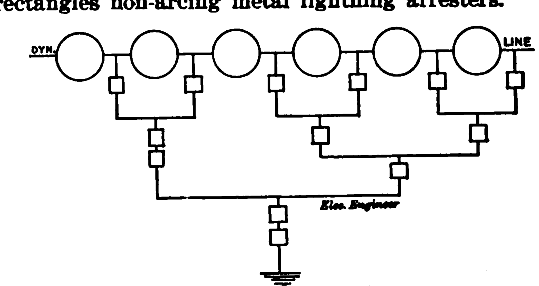

FIG. 5.—CONNECTION FOR 10,000 VOLTS.

To illustrate the great saving in space and number of lightning arresters required by the pyramidal form of connection,

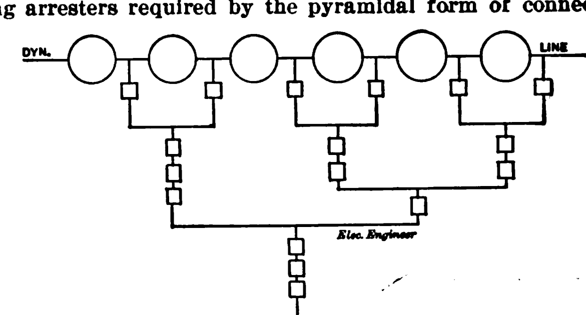

FIG. 6.—CONNECTION FOR 15,000 VOLTS.

it will be noted that in Fig. 6 there are at each lightning arrester connection to the line seven unit lightning arresters between line and ground, making a total of 17 lightning arresters; whereas, with the old method, where seven inde-

pendent lightning arresters were connected between line and ground at each point of connection to the line, forty-two lightning arresters would have been required.

The engravings, Figs. 7 and 8, illustrate the lightning arrester rack, with coils and arresters in position, for one end

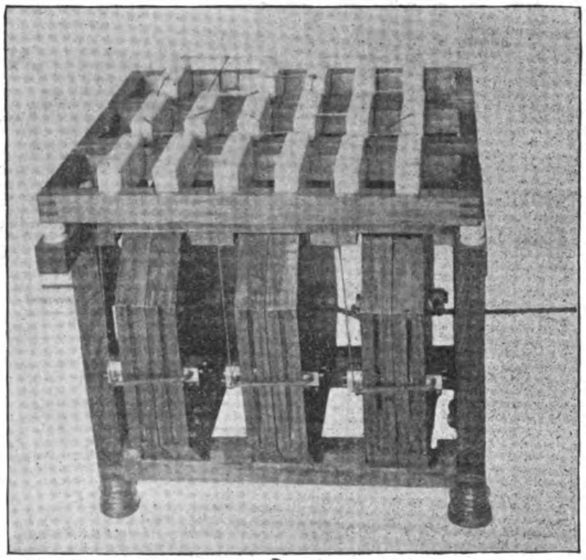

FIG. 7.—THE WURTS PYRAMID LIGHTNING ARRESTER.

of one wire of a 15,000 volt alternating current circuit. The arrangement and electrical connections correspond exactly to those shown in Fig. 6. The connections between the unit lightning arresters on top of the rack are made with No. 10 wire, bent ┌──┐ shape, as shown. Diagrammatical plan view of the lightning arresters and their connections for each voltage are shown in Figs. 9, 10, 11, 12 and 13. These connections correspond respectively to the connections shown in Figs. 2, 3, 4, 5 and 6. For the protection of power transmission circuits, one lightning arrester rack should be connected at each end of each wire, regardless of the number of phases. The

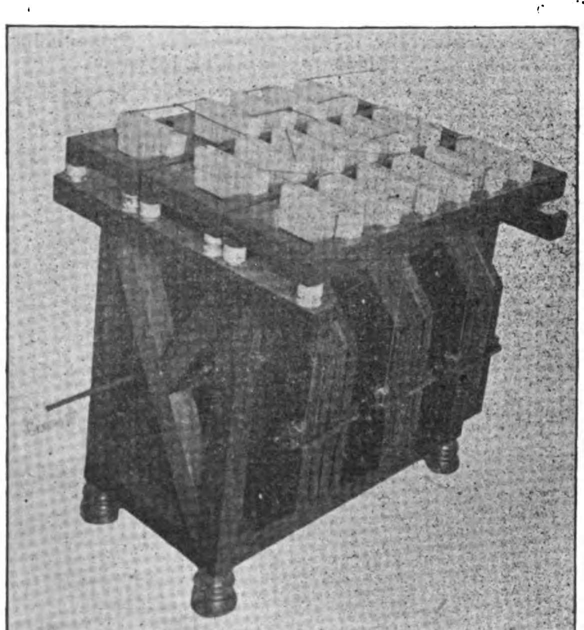

FIG. 8.—THE WURTS PYRAMID LIGHTNING ARRESTER.

apparatus should be located in a dry place and with proper reference to insulation, safety and a good ground connection.

Especial attention is called to the importance of making a thoroughly good ground connection. It is obvious that a poor ground connection will render inefficient every effort made with choke coils and lightning arresters to drive the static electricity into the earth. It is therefore important that we should not only understand how to construct a good ground connection, but also thoroughly appreciate the necessity of avoiding unfavorable natural conditions.

A good ground connection may be made in the following

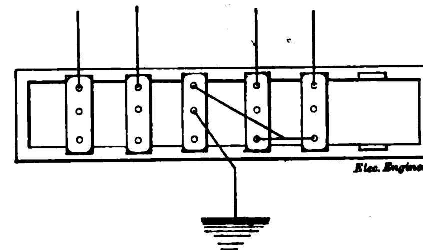

FIG. 9.—CONNECTION FOR 3,000 VOLTS.

manner: First, dig a hole six feet square directly under the arresters until permanently damp earth has been reached; second, cover the bottom of this hole with two feet of crushed coke or charcoal (about pea size); third, over this lay 25 square feet of No. 16 tinned copper plate; fourth, solder the ground wire, preferably No. 0 copper, securely across the entire sur-

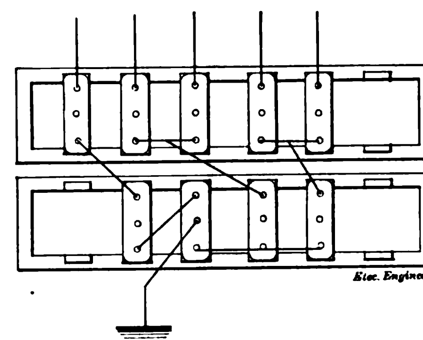

FIG. 10.—CONNECTION FOR 5,000 VOLTS.

face of the ground plate; fifth, cover the ground plate with two feet of crushed coke or charcoal; and sixth, fill in the hole with earth, using running water to settle. The above method of making a ground connection is simple and has been found to give excellent results, and yet, if not made in proper soil, it would prove of little value as a connection to

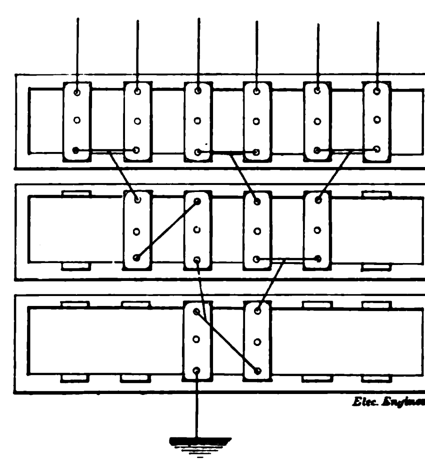

FIG. 11.—CONNECTION FOR 8,000 VOLTS.

earth. Where a mountain stream is conveniently near it is not uncommon to throw the ground plate into the bed of the stream. This, however, makes a poor ground connection, owing to the high resistance of the pure water and the rocky bottom of the stream. Clay, even when wet, rock, sand, gravel, dry earth and pure water are not suitable materials in which to bury the ground plate of a bank of lightning arresters. Rich soil is the best. It is therefore advisable before installing a bank of choke coils and lightning arresters to select the best possible site for the lightning arrester instal-

lation, with reference to a good ground connection. This may often be at some little distance from the station, in which

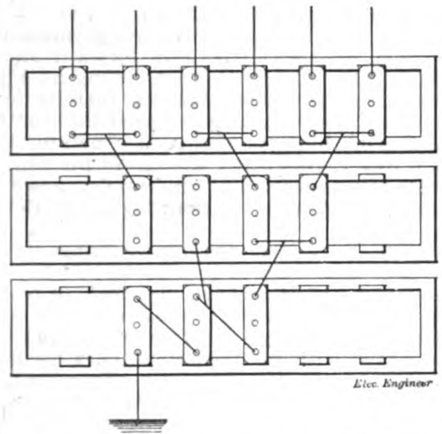

FIG. 12.—CONNECTION FOR 10,000 VOLTS.

case it is of course necessary to construct a lightning arrester house. Where permanent dampness cannot be reached it is

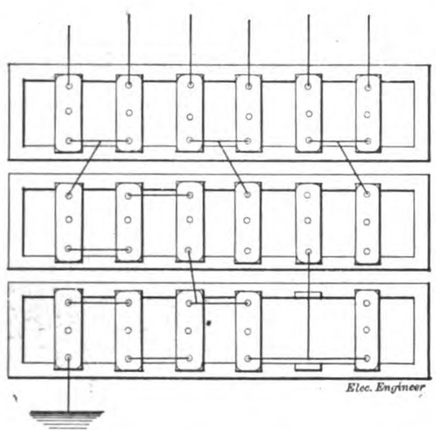

FIG. 13.—CONNECTION FOR 15,000 VOLTS.

recommended that water be supplied to the ground plate through a pipe from some convenient source.

ELECTRIC COAL MINING IN OHIO.

According to the annual report of Mr. R. M. Haseltine, chief inspector of mines of Ohio, 3,120,456 tons were mined by machinery. There are 31 mines in the State equipped with machines. In these 82 of the machines are operated by electricity and a like number by compressed air; 447 hands are employed in operating the machines, and 3,374 hands in blasting down and loading the coal after it has been undercut by the machines.

THE TESTING DEPARTMENT OF THE GENERAL ELECTRIC COMPANY'S WORKS.—IV.

BY THEO. STRAUS.

(Concluded.)

Like the entire works the testing department itself is divided into sections, as referred to above, which form together one great unit.

In each section is apparatus especially adapted for its assigned purposes, and this, together with the facilities for wiring

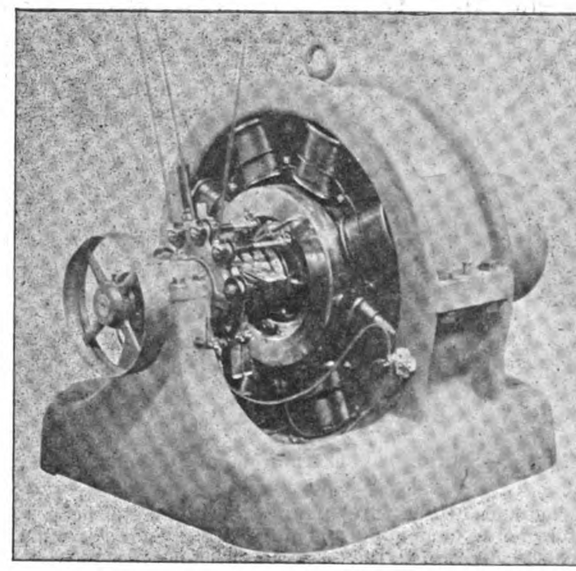

FIG. 8.—THREE PHASE COMPOUND WOUND GENERATOR.

and connecting the machines, enables a test to be run off without unnecessary work.

The diagram, Fig. 7, shows the manner in which the testing building is divided for the various tests, as follows:

(1) Tests of small motors and generators under 25 kilowatts.—Slow and moderate speed direct and belt driven; generators and motors (multipolar and I. B. types); direct connected (blower) motors; direct connected (air pump) motors.

(2) Tests of large motors and generators above 25 kilowatts.—This is the most varied of all the sections, containing all the large machines, both direct and alternating current. Some of these are: Direct and belt driven multipolar, railway and power generators. Multipolar motors.—Slow and moderate speed belt driven generators and motors (multipolar); alternating current generators single-phase, 125 cycles; three-phase generators and synchronous motors, 60 cycles; monocyclic generators, 60 cycles; the 3-phase compound machine is shown in Fig. 8.

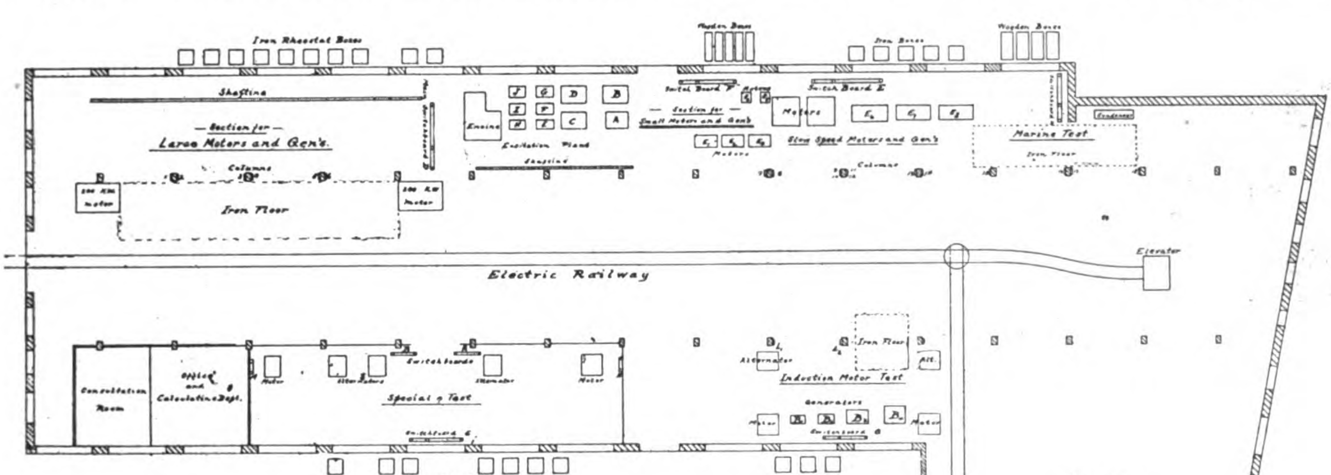

FIG. 7.—PLAN SHOWING ARRANGEMENT OF TESTING BUILDING, GENERAL ELECTRIC COMPANY, SCHENECTADY.

(3) Marine test.—This, as its name indicates, comprises all machines designed for marine work, both for commercial and U. S. Government work. The machines (generators, ironclad motors, etc.) are divided according to the above classification, those for the first class being wound for 110 volts and for the latter, the U. S. standard of 80 volts. The generators are directly connected with vertical double cylinder engines, designed and built by the General Electric Company; a row of these marine units undergoing test is shown in Fig. 9. Tests in this section are therefore both mechanical and electrical

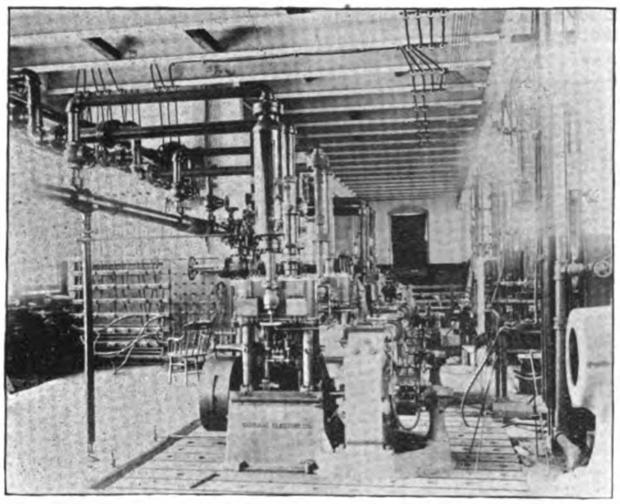

FIG. 9.—SECTION FOR TESTING MARINE GENERATORS.

and permanent fittings are arranged for this purpose. The generators being compound machines, are given the regulation tests, except those for the U. S. Government, which before acceptance conducts through its engineering corps a special series of tests. The engines are first run free (no load) allowing the bearings and cylinders to acquire a good wearing surface. After the governor is regulated so that the change of speed from no load to full load is not more than 2 per cent., the machine is tested. Besides the readings on the generator, the steam pressure and indicator cards (from which the watts per horse-power are calculated) are taken.

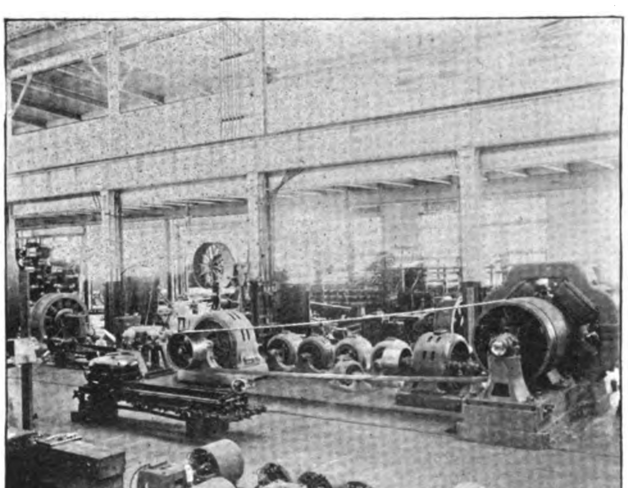

FIG. 10.—SECTION FOR TESTING INDUCTION MOTORS.

Induction motor and potential regulator test.—All induction motors are given a commercial test consisting of the following: Heat run (full load); speed test (no load); speed test (full load); maximum output; magnetizing current; static impedance. This testing department is illustrated in Fig. 10.

The test given to the potential regulators are: Heat run, maximum boost (full load); maximum boost (no load).

(5) Railway motor test.—All railway motors are tested here; these are: G. E. 800, with 2, 3, and 4 turn armatures; G. E. 1,000, with 3 and 4 turn armatures; G. E. 1,200 with 1, 2, 3, and 4 turn armatures; G. E. 51, recently designed especially for the Brooklyn Bridge; N. W. P. 2½, mining locomotives; N. W. P. 12, mining locomotives; N. W. P. 20, mining locomotives; L. W. P. 5, for crane work; L. W. P. 20, for crane work.

In testing these machines two motors of similar type are connected to one axle by gears, as shown in Fig. 11, the same method being used as when the motors are permanently set up in the cars. Then one is run both in forward and reversed directions as a motor, while the other, acting as a generator, sends its current into a water rheostat, thereby loading the motor. After a sufficient time has elapsed the combination is reversed, and the machine running as a generator is now the motor, and the test is conducted similar to the first combination. The tests given are: Heat run (under a severe load); heavy overload; resistance; insulation; high potential (alternating current).

(6) Special test.—Each machine representing its type and class is given a complete set of special tests. They are made most accurately and are correct within a half of one per cent.

The results obtained from these tests are computed by the calculating department, worked up into curves and convenient forms and compared with the theoretical data used in designing the machine. These, together with the general remarks, are embodied in a report and placed on file easily accessible to the engineering corps.

Although the main testing is accomplished in building No. 11, nevertheless, scattered in the various buildings, are individual testing departments.

According to the character of the work produced in the buildings, so are these fitted and arranged as a machine advances towards its final state, piece by piece is sent to these departments and tested. As a result of this very little trouble is developed during the final test after completion.

No apparatus leaves the works, without having some kind of

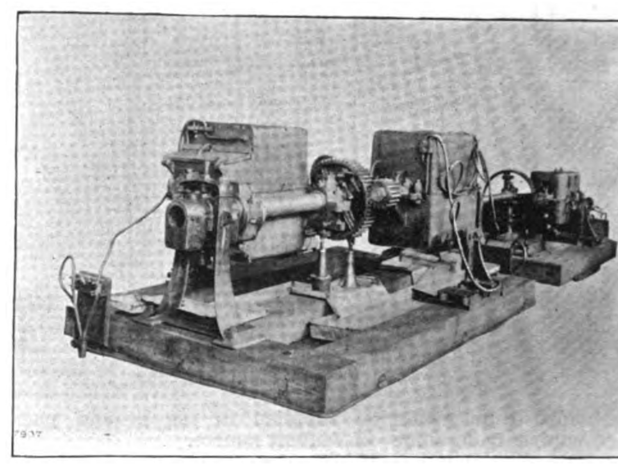

FIG. 11.—METHOD OF TESTING RAILROAD MOTORS.

a test, and if not sent to building No. 11, it is tested in the building where constructed. A partial list under this classification is as follows: Automatic circuit breakers, rheostats, Edison chemical meters, porcelain insulators, controllers, lightning arresters, searchlights, etc.

Like the other parts of the works the testing department is so conducted that nothing is allowed to "slip through" under any pretext, no matter what the cost may be. This is a broad policy, and in the end, as the good results indicate, reaps its reward.

NEWS ABOUT THE AUSTIN, TEX., MUNICIPAL PLANT.

A special dispatch from Austin, Tex., says: At the City Council meeting to-night, Superintendent John Maddox tendered his resignation, and in doing so, in a lengthy communication, he called attention to the inefficiency of the pumps and of the line shafting, which, he said, endangered the safety of the plant. He also called attention to the absolute necessity of removing the plant from the political arena. He characterized some of the dynamos as mere rattle traps and urged the abandonment of the scheme to build a reservoir, and suggested many changes in the shafting and in doing away with belts. The resignation was to take place when his successor was appointed and qualified, but the council upon motion accepted it to take effect immediately.

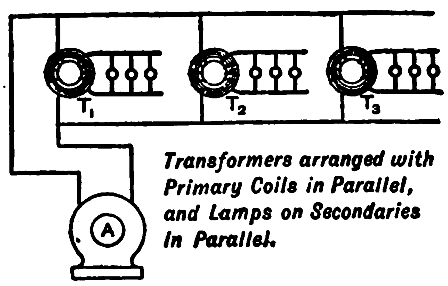
PAWTUCKET, R. I.—The project to establish a municipal electric lighting plant, which has been under consideration in the City Council for the past few months, has been defeated by the action of the Board of Aldermen.

ALTERNATE CURRENT TRANSFORMERS.—VII.

BY DR. J. A. FLEMING, F. R. S.

THE EMPLOYMENT OF TRANSFORMERS.

IN this last lecture I wish to direct your attention to certain problems in connection with the employment of transformers. I shall assume that the majority present are quite familiar with the ordinary methods of distributing electric current by means of transformers, whether by what is called the system of distribution by house transformers, as shown by Fig. 47, or the more modern and economical method by transformer sub-stations. Generally speaking, the method of transformer distribution which is now found to be most practically useful in provincial towns and over large areas is somewhat as follows: In the generating station, the alternators either send their current into one common set of omnibus bars, the alternators working in parallel, from which bars a distribution is made by high tension feeders to various transformer sub-stations. Often a more complicated switchboard is employed in which the high tension feeders coming from the various transformer sub-stations can be connected at pleasure to any alternator, or grouped together in any way on one or more of the alternators. It would be foreign to our subject here, at the present moment, to enter at all into the question of the parallel working alternators. It has been fully discussed in the technical journals and other publications. The high tension feeders are generally arranged to convey a high tension current at a pressure of 2,000 volts to certain transformer sub-stations in which are placed a bank of transformers. These transformers take their primary current through primary switches and fuses from primary omnibus bars connected to the feeders, and the secondary circuits of the transformers are generally arranged to feed a three-wire system of low-tension distribution. For



Transformers arranged with Primary Coils in Parallel, and Lamps on Secondaries in Parallel.

FIG. 47.

this purpose each transformer is provided with three secondary terminals, and from the sub-station proceeds a three-wire low-tension system which is fed by one or more of the transformers, and to which the consumers are connected. In joining up a bank of transformers in this manner it is important that each of the transformers should have an equal percentage secondary drop for the same fraction of a full load. Otherwise, if one transformer has a smaller secondary drop than another, that transformer with the least secondary drop will take the greatest share of the load as the sub-station is loaded up, and it may, therefore, get overloaded and get very hot, and such an inequality of load tends to increase, the more the bank of transformers is loaded up. It is always advisable to examine transformers in this manner, and if any transformer is found to have too large a secondary drop then to remedy it by adding one or more turns to the secondary circuit. In addition to a low tension distribution from transformer sub-stations it is sometimes found convenient to run one or more high-tension feeders to supply the outlying regions of the district which is then served with a system of house transformers. The plan which I have found convenient to adopt in developing an alternating current station in a provincial town in which there is a central shop district, in which the lighting is rather dense, and an outlying residential district in which it is rather scattered, is to arrange one or more low pressure secondary networks on the three-wire system in the central portion of the town. Each of these networks is fed from a single transformer sub-station, and the secondary circuit forms a complete ring main, which is fed into by secondary feeders at three or four places. The transformer sub-stations are inter-connected by a high pressure connecting main, which serves, in case of breakdown at one station, to allow the duty of that station to be taken up by another sub-station. It is not advisable, in my opinion, to connect together the different, separate, secondary networks. One great advantage of the alternating current system is that it enables us by having small secondary distribution systems perfectly insulated from one another, to limit the effect of a dead earth on one of these secondary networks, and that is an advantage which cannot be obtained on the ordinary low pressure system where the distribution network is connected throughout.

As regards the description of cable to be employed, it is now well understood that concentric cable forms in all cases the most satisfactory of cable both for the high pressure and the low pressure conductors. By the employment of concentric cable, we eliminate at once any difficulties which would arise due to induction taking place on neighboring telegraph and telephone wires; and we also largely reduce the inductive drop in pressure which would otherwise exist if the three members of the secondary circuit were separate cables separated by any distance from one another. My own experience is that the secondary network is best laid down by means of triple concentric cable, and there are certain advantages in making the outer member of this cable the middle wire of the three conductor system. In any case, the house connections are quite easily made. It is also desirable to get rid altogether of distribution boxes and service boxes, which become localities in which coal gas can collect and occasionally explode. In laying down the secondary distribution system by means of lead covered and armored triple concentric cable, by far the best plan is to make the proper connection with a service main to each house at the time that the cable is laid, and to have this joint entirely sealed up in lead, making use of no junction box at all, or at most of right angle iron sleeve to mechanically protect the joint. The service main can then be taken into each shop or house, and connected up to the consumer's terminals, whether the building takes light or not. In the central portions of a town it is only a question of time for every shop or house to take the current, and it saves expense ultimately to make this joint in the first instance. The secondary cable having been laid in this manner should be tested, and my own practice is to insist upon a test of 1,000 volts between the different members of the secondary circuit when it is laid in the earth, but before the house connections are made. If the cable stands this test it has a large factor of safety.

ELECTRICITY IN NAVAL LIFE.—II.

BY LIEUT. B. A. FISKE, U. S. N.

THE principal advantage of hydraulic engines over steam and pneumatic engines, arising from the incompressible nature of water, is the absolute rigidity with which they hold the turret. If the valves are closed the turret cannot move; and the turret can never make the water motor go at a greater speed than that for which it is set. In the sighting hood, the continuous turning of a wheel by the operator at any desired speed controls, on the floating lever principle, the speed at which the turret shall go. The muscular effort required is so considerable that he is compelled at frequent intervals to remove his eye from the axis of collimation of the telescope, which is almost fatal to fine shooting. Now electrical men show that they can attain fully as much nicety and precision by electric means, using a controlling switch so easy to move that the eye can be kept continuously at the telescope until the instant of fire; and, furthermore, they proceed to point out how pipes burst and valves leak just when called upon to work. In most, if not all of the plans hitherto tried for electrically training turrets, however, control of the motor's speed has been sought through the putting of more or less resistance in the circuit of the armature. The difficulty of handling large turrets by this means is, of course, great, and the means thus far employed can hardly be called satisfactory. They do not need describing here, because in fact they are bad and should not be used. In determining why they are bad, let us consider what is needed in order to control the training of a turret in a sea-way. The turret weighs a hundred tons or more, and it is rare that its center of gravity is in the axis of rotation. As the vessel rolls from side to side, the turret tends to move by its weight in one direction or the other, the effect being at a maximum when the guns are pointing ahead or astern. Let it be supposed that the turret is pointing ahead and is stationary, and that the turret captain wishes to train it to point at a target on the starboard beam. He moves his lever to the front and the turret starts to turn slowly, the great mass of the turret preventing its suddenly taking up a rapid motion. Just now the ship begins to roll to port and the turret has to climb up hill, besides being accelerated. As the roll continues the hill becomes steeper, until it reaches a maximum, and then it becomes less and less steep, until an even keel is reached. This has taken—say, eight seconds, and the turret has just about reached the speed at which it is intended to run, when the ship starts to roll to starboard; the turret now tends to run down hill, and the motor is doing its best to help it. Evidently the arrangement of the motor must be such that without any conscious effort from the operator, the turret will

not be permitted to run down hill, for the mass is so great that the consequence of mental confusion or inattention on the part of the operator might be serious. In other words, the motor must be arranged so that it cannot run above a certain speed. This is usually expressed by saying that we must use a "constant-speed motor."

It has been objected frequently, however, that constant speed is not needed, or even desired; that what is wanted is simply ability to get the turret quickly around to the target, and to move it quickly to the right or the left in order to keep the guns pointing at the target.

Without wishing to detract in any way from the importance of these points, it must be insisted that everything should be done to make the gun captain's work easy, that his mind should be as free as possible from mental calculating, his lever as easy to move as practicable, and that the movement of the turret should bear a definite relation to the movement of his lever. Let us suppose that this is not done and that the turret's speed depends on other causes than the movement of his lever. Is it not plain that the captain will have to jerk his lever around more frequently and spasmodically than he would if each position of his lever meant a certain speed? If each position of his lever can be made to mean a certain speed, regardless of everything external, is it not plain that with a little practice, and even if the gun captain does not know anything in figures about either the position of his lever or the revolutions of the motor, he will yet insensibly come to feel that he with his own arm is moving the turret, and that his own will controls its speed? Can he not then follow a moving target with far greater precision than would be possible if the turret would spasmodically speed up or down from moment to moment as the ship rolled?

It is not an answer to this to say that it is impossible to get constant speed under the circumstances, that the speed and direction of the turret must frequently be changed, that it will always take a certain interval of time for the heavy mass to make the change, and that during the interval the speed of the turret will be either increasing or decreasing. This objection, while it includes a true statement, is really misleading, because it amounts to saying that, if perfect control of any machine cannot be obtained, we should therefore refrain from attempting to make the control of the machine as perfect as we can. To attempt the control of a turret in a sea-way is like trying to solve a problem containing many variables; and it is axiomatic that the solution of any such problem is easy in proportion to the reductions we can make in the number of variables. Applying this principle, we are forced to the conclusion that the motor for the turret should be so arranged that its speed shall vary as little as possible from the speed set by the gun captain. Now, it is not hard to get a constant-speed motor; but unfortunately for any given electric potential applied to an electric motor, there is only one speed that can be constant; so that, in order to make a motor run at different constant speeds, different potentials must be applied, and each potential must itself remain constant during the interval of time for which the corresponding speed is desired. In other words, in order that the gun captain in the sighting hood may be able really to command the speed of rotation of the turret, he must be provided with a system by means of which the potential which he applies to the motor shall not change, unless he himself intentionally changes it. Reverting now to the statement made before, that all methods of controlling turret motors are bad in which resistances are varied in the armature circuit, we see at once that it must be bad if the potential applied to the armature terminal is liable to change. That it is liable to change is easily proved, as follows:

If an electric motor is running at any speed, and if its load be suddenly increased by any cause, such as in this case, by an increase in the heel of the ship when the turret is running up hill, the motor tends to slow down; this reduces the counter electromotive force that the motor is generating and therefore increases the current in the armature. Now if a certain resistance (say $^1/_{10}$ ohm) has been put in the armature circuit when the armature current was 100 amperes, then, since $E = CR$, the voltage expended in heating this resistance $= 100 \times {}^1/_{10} =$ 10 volts, and the voltage of the armature terminals falls from 80 volts to $(80 - 10 =)$ 70, so that the motor is running really on a 70 volt circuit. Let now the load be increased so that the current increases to say 200 amperes; the voltage now lost in the resistance $= 200 \times {}^1/_{10} = 20$ volts, so that the motor will run at 60 volts instead of 70 volts. The action, then, of an increased load on the motor has been to decrease the power supplied to it, which is just the reverse of what was wanted.

In endeavoring to meet this trouble, Mr. Ward Leonard devised a system which is in use considerably for working large cranes and elevators. By this system the speed of a motor is regulated by increasing the potential applied when it is desired to increase the speed, and decreasing the potential when it is desired to decrease the speed. To accomplish this, Mr. Leonard runs an auxiliary motor direct from the electric mains, and this motor has a dynamo of about the same size on its shaft, so that the motor turns the dynamo and makes it generate a current, which current goes to the armature of the motor that does the work. The magnetic field of this working motor is excited direct from the main circuit, and so is the field of the dynamo which the auxiliary motor turns. But there is a variable resistance placed in the field of the dynamo circuit. Now by putting in more or less of this resistance in the field, the electromotive force, generated and sent to the working motor, is decreased or increased, and the working motor is governed with astonishing precision. As the current, moreover, in the fields is always small, the great difficulty is avoided which always exists in putting resistance into or out of circuits having heavy currents.

One great objection to this method is the obvious one that two motors and a separate dynamo are required to do one motor's work and the additional motor and dynamo must each be at least as large as the working motor. In the U. S. S. Brooklyn, two of the turrets are to be turned by electricity and two by steam, the idea being to have an absolutely fair competitive test under service conditions at sea. A novel plan suggested by the writer is to be tried which need not be described here, as it will not be interesting unless it prove successful.

Besides constancy in speed there are two other principal desiderata in the turning of a turret: first, sufficient speed of turning to bring the guns on to a target, and to follow it when its direction is changing, and second, extreme nicety of movement, which means ability to quickly move the guns in one direction or the reverse through small angles, and to stop it quickly when desired.

In deciding upon the speed required, the question resolves itself merely into deciding how much money and space can be provided for the power, because the highest speed attainable is desired. The speed, however, ought to be at least that necessary when two ships 1000 yards distant are passing each other at fifteen knots each, because this situation may nearly occur. Two ships passing each other at this distance and speed change their relative directions per second through an angle the sine of which is

$$\frac{(15 \times .57)\ 2}{(1000)} = \frac{17.1}{1000} = \sin 1^\circ \text{ (approx.).}$$

This speed is clearly much less than would be required for handling the gun in a sea-way, having regard merely to the uncertain motion of the ship itself. So in our new ships, the speed specified is many times this, even under a considerable heel, when the turret will have to run up hill.

The problem of quickly turning the turret becomes afterwards one for the electrical engineer. He is told that the weight of the turret is so many tons, that the friction is so much, that the center of gravity is so many inches from the center of rotation, and that he must make the turret run at a certain speed. The question is so far one of horse-power. But he must also be told that the motor must be so designed that it will not become stalled (i. e. unable to move) under any probable roll, because, when a motor's armature is stationary the current through it is enormous, being $(C = E \div R)$ that due to the potential between the mains (in the United States Navy 80 volts) and the ohmic resistance of the armature itself. To guard against an excessive current, in case an extraordinary roll should stall the motor, it is well to put an electro-magnetic cut-out in the armature circuit, which will automatically break the current if it exceeds an amount for which the cut-out is adjusted.

As it would be impracticable to provide sufficient power to maintain constant speed under heavy rolls, it becomes necessary to prescribe that the speed shall be constant up to a roll of say 10°, and permit that it may slow down when the angle of heel is greater, being careful that the speed shall never fall to zero under any probable circumstances.

The question of nicety of train, in the case that abundant power has been provided for the efficient rotation of the turret under ordinary rolls, is largely one of the construction of the switch which the gun captain moves. As the gun captain views the target through his telescope, the vertical and horizontal cross wires appear to be describing irregular curves against the background of the sky. His effort must be to bring these curves into the vicinity of the target. Though the motions of the cross hairs are seemingly erratic, they can, of course, be resolved into two motions, one horizontal and the other vertical. If the advance of the ship was in an absolutely straight line, and if the ship rolled the same amount from side to side and at regular intervals, the curve of the point of intersection of the cross hairs would be regular, and it would be comparatively easy to bring this intersection on to the tar-

get. But it is rare that a ship moves exactly in a straight line, in a sea-way, even when steaming on a certain course, for she yaws gently from side to side. Neither does a ship roll regularly. Even under the best circumstances she rolls a little more to one side than to the other, and the rolls vary in amount from time to time. Then a ship frequently comes to rest for a while on an approximately even keel, and then starts to rolling again. Besides the rolling there is also the pitching, and this complicates the motion of the cross hairs, especially when the guns are pointing on the bow or quarter. The up and down motion is the quickest and the most irregular, so that the real problem is to so move the turret as to get the vertical cross hair on the target at the instant when the rolling throws the horizontal hair across the target, and to press the firing button at that instant, changing the elevation of the gun itself as little and as seldom as possible. With a large field in the telescope the vertical wire shows the direction in which to move the turret, even when the horizontal hair is several degrees above or below the target, so that the success of the gun captain, or rather of the man who is charged with the training of the turret in azimuth, in keeping the vertical hair across the target is dependent on the ease with which his switch can be moved, as well as on the response of the motor to the switch; and it is absolutely essential that the moving of his switch must not in the least disturb the position of his eye at the telescope. For this reason the motion of the switch must be to the front and rear, and not to the right or left.

STEERING BY ELECTRIC MOTORS.

This has been accomplished in several vessels, the most recent apparatus being in some "whale-backs" on our great lakes. The writer secured three patents some eight years ago on electric steering, but has not as yet had an opportunity to get his system tried. One of the patents covered broadly "the method of controlling electric motors whereby the motor follows the motions of the operator's hand in speed and direction," just as is done by the ordinary steam steering engine and the ordinary ash hoist. In the "Brooklyn" the experiment will be made of steering by electricity by means of what is called a tele-motor. The apparatus will be installed by Williamson Brothers of Philadelphia, who have made so many of the steam-steering apparatus for our new warships and merchant-ships that they may be presumed to understand the requirements of good steering. There is more doubt, perhaps, about the advisability of using electricity for steering than for any other of the uses to which auxiliary engines are put in ships, because nobody wishes the steering machinery to be otherwise than absolutely reliable, and because steam-steering machinery is now so good that little is left to be desired. Electric steering, therefore, must at present be considered as doubtful, and the burden is on it to prove its value. Meanwhile foreign nations are also experimenting on it; and Messrs. Williamson Brothers do not wish to publish their own plans until they have achieved success.

ELECTRIC FIRING OF GUNS.

When one reflects that a vessel rolls from side to side in about eight seconds on an average, that even under very good circumstances she rolls more than one degree per second, and that with the modern guns an error of ten minutes of arc in the elevation of a gun above the horizontal at the instant it is fired means an error of about 200 yards in the distance the projectile will go, and that in the case of a ship 2,500 yards distant this error of ten minutes of arc will throw the projectile about twenty-two feet above or below the point aimed at, we see that it is necessary to fire the gun in such a way that a less time than ten-sixtieths = one-sixth of a second of time will elapse between the time that the gun captain makes up his mind to fire the gun and the time that it is actually fired; unless the gun captain resorts to the method of firing his gun before his cross hairs rest on the target, by an interval of time which he estimates will be such that when the gun is actually fired the cross hairs will actually rest on the target. Of course, this method is often used with great success, and a "born shot" can, with sufficient practice, so use it; in fact, "born shots" do successfully use it, but only "born shots" can, and even they need more practice than is given or can be given in any navy in the world. To place accurate gun firing within the reach of ordinary men, electrical firing is used, in which the captain can fire without taking his eye from his telescope (or sights), and by such a slight pressure of his fingers that he can fire very quickly after making up his mind to fire, and (which is fully as important) without moving his eye from the telescope. Practical results show more accurate firing with electricity than with either percussion or friction. Complaints are sometimes heard of the untrustworthiness of electrical firing; but if electrical firing apparatus is properly installed, it is more simple and trustworthy than any other means. The real trouble is that as yet there are not enough people on shipboard who understand electrical apparatus. As to the concentration of fire by electricity, it has few friends and they are thinning out rapidly, as the system serves no useful purpose.

The advantages of electrical firing over percussion and friction firing are therefore two-fold. First, the time elapsing between the instant when the gun captain makes up his mind to fire and the instant when the gun is actually fired is very much shortened; second, the gun captain is able to keep his eye on the line of sight until the gun is actually fired, because, since his fingers alone have to act, his head is not jerked to one side, as it is by the physical effort of pulling a lock-string. These advantages are not very evident in the case of firing by the use of the ordinary bar-sight, because the gun captain stands several feet away from it (the bar-sight), and his line of sight is so uncertain that a little more uncertainty does not seem to make much difference. But the whole matter is changed as soon as one comes to look through a telescope sight, because then the line of sight is so absolutely defined that one knows exactly what he is pointing at, and he sees just as soon as he tries to pull a lock-string that by the time he gets the lock-string pulled his telescope sight has been moved by the motion of the ship, so that it no longer points at the same thing at which he pointed when he made up his mind to fire, but points at some other place. A long essay might be written to prove the reasonableness of electric firing, but it would not be half so convincing as a single look through a telescope sight when the ship is rolling, even as slowly as one degree per second. A change of one degree in elevation, let it be remembered, means a change of about 1,000 yards in range on the average.

The details of electrical firing have given a good deal of trouble, but they seem pretty well worked out now. It is to be hoped that every "bug" will soon be overcome, because otherwise (since foreign navies are so successful with electrical firing) the U. S. Navy will have to give up its pre-eminent reputation for fine gunnery. The single wire sytem is the one adopted in our Navy, in which one end of the fine platinum-iridium fuse wire, which is heated by the firing current, is electrically connected to the metallic body of the primer. As one pole of the firing battery is connected to the metallic carriage holding the gun, and as the metal of the primer is in contact with the gun, the circuit is completed when the gun captain presses his firing button; then the current heats the fuse wire, and the heat communicated to the primer ignites it and fires the charge.

The idea so long mooted and so much tried, of firing an entire broadside by the electric current controlled by the captain, seems rapidly falling into disfavor. There are so very many chances of failure, there are so many connections required, and the result hoped for seems so small an improvement over broadside firing by order, that "le jeu ne vaut pas la chandelle."

ON THE NOTATION OF TERRESTRIAL MAGNETIC QUANTITIES.

BY L. A. BAUER.

AT the International Meteorological Congress to be held in Paris, a number of questions of special interest to magneticians have been proposed for discussion, among which is the following: "The same notation should be generally employed, H for horizontal force, X for the northern component, Y for the western component, Z for the vertical force, and V for the potential." As the need of some uniform notation has been made apparent to me in connection with the journal "Terrestrial Magnetism," I have been paying this matter some attention with the view of obtaining a concise and logical system for adoption in that journal.

The principle upon which I proceed is to take the first letter of a word designating a particular quantity, if at the same time it conforms with typographic requirements, such, for example, as declination, which is common to several languages. In this way I have thus far obtained the following: D for declination, I for inclination, H for horizontal component of force, V for vertical component, F for total force. Upon examination it will be found that these letters stand for words derived, in almost all cases, originally from the Latin and Greek languages, and with but insignificant variations in spelling, common to several of the main modern languages.

The Germans will be asked to yield a point with regard to F,[1] but this, as will be seen below, will be made up to them in the adoption of G for magnetic potential. V taken from the Latin vis, or I from intensitas, or D from the Greek word

δύναμις, would not do for force, as they are already taken. Nor would T from totus or P from πας answer, since the former is frequently used for time of vibration, and so in fact is the letter P, which stands besides for the first deflection coefficient. As I hope to be able to find a satisfactory notation for all the principal magnetic quantities, I am keeping this matter constantly in mind in adopting any particular letter. The English and French have force, and I have, therefore adopted F for total force. As it is frequently the custom to designate angular quantities by Greek letters, I should have preferred, had it been possible, to adopt δ and ι instead of D and I, but the Greek ι is a very unsatisfactory letter from a typographical standpoint. Moreover, if found desirable later on, the small letters d and i or δ and ι can be reserved for the variations on the mean of day and on the mean of year respectively.

I think it very much to be deplored if Z, as above proposed, be universally adopted to designate the vertical force. It should not be forgotten that the Gaussian mode of resolving the magnetic force into northerly component (X), westerly component (Y), and vertical component (Z), applies to a local system of co-ordinates, not to a fixed system, as the layman might naturally suppose—a fact which is even apparently forgotten at times by magneticians. The mean values of these components for a complete circuit of the earth along a parallel of latitude can, in consequence, no more be physically interpreted than the mean H, for example. I am, therefore, opposed to adopting for the vertical force a letter which in no way gives evidence of the exact quantity for which it stands. V, on the other hand, is logically connected with H, and at the same time implies that the direction of the quantity that it symbolizes is local, the direction of the vertical or plumbline varying from point to point.

For the same reasons I am not in favor of adopting X for northerly component, and Y for westerly component. Let authors choose this method of notation, if they prefer it; but in a system suggested for universal adoption, it would seem to me that N and W would more satisfactorily meet the requirements, clearly indicating to the eye as they do the local character of the system of co-ordinates employed.

As a letter to designate the earth's magnetic potential, I believe none more fitting could be adopted than G, after Gauss, the author of this function. Gauss himself used V, but this letter is not sufficiently characteristic; it is used to designate many other functions in mathematical physics; and there would, moreover, be a conflict in our system, since V seems the most logical letter to designate the vertical force.

ROENTGEN RAYS.

NEW FORM OF APPARATUS FOR THE PRODUCTION OF ROENTGEN RAYS.[1]

BY BENJAMIN DAVIES.

SOME time in the month of March, this year, after working with various forms of tubes, it occurred to the writer to abolish the glass vessel by converting the ordinary concave cathode into a nearly complete sphere, with the platinum anode at its center. A simple experiment with a Jackson bulb proved that the rays from the anode could pass through the material of the cathode as they would through a similar piece

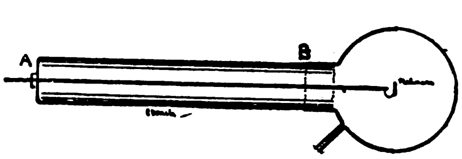


FIG. 1.

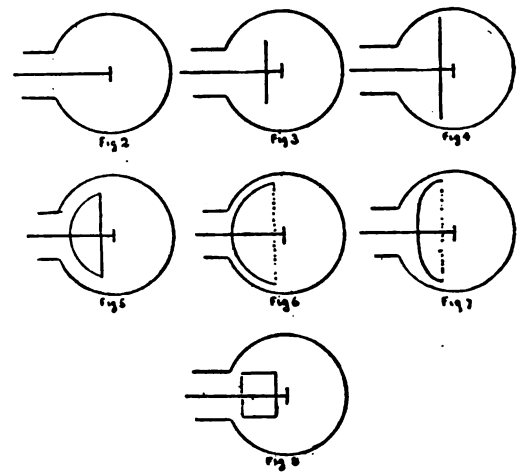
of unelectrified aluminum placed outside the bulb. Hence it became fairly evident at the outset that the proposed plan would work to some extent.

Under the guidance of Professor Lodge, and in his research laboratory, experiments were commenced. The first arrangement was a simple one. The sphere was made in two halves, one half of copper and the other of aluminum. The two halves were joined together with marine glue only. The anode was held in position by ebonite fixed in the copper hemisphere. A section of this simple arrangement is shown in Fig. 1. The section is drawn to scale, the diameter of the sphere being two inches. This early apparatus showed signs of success, and it was decided to invest in a larger sphere—one of 3½ inches in diameter. The joints were now made much more carefully, and the apparatus so designed that it could be fitted together or taken to pieces in half an hour's time. The hemispheres of copper and aluminum were soldered together, but the joints (A and B, Fig. 1) were made by compressing India rubber washers by means of suitably made screws. With this convenient apparatus the behavior of various sizes and shapes of anodes was observed. In all the experiments a small thick plate of platinum, having a plane surface of about ¼ square inch, was reserved for that portion of the anode which re-



FIGS. 2 TO 8.

ceived cathode rays; the remainder of the anode was sometimes of aluminum and sometimes of copper. The various forms tried are shown in Figs. 2 to 8.

In Fig. 2 we have the simplest possible anode—the platinum plate alone. It is the same arrangement as that of Fig. 1, the only difference being that of dimensions. This form possessed an enormous resistance, so that only with low vacua could a current be made to pass through. For this reason the behavior of this form was unsteady and its periods of activity very short. With higher vacua and greater potentials, no doubt this form would be more successful. Another form tried was that shown in Fig. 3. The anode here was very considerably enlarged by placing a circular plate of metal just behind the platinum at a place where no cathode rays could fall on it. By this means the area of the anode surface was increased sixteen-fold approximately. The resistance was thereby much reduced, and it became possible to work at higher vacua. This form gave a more powerful and a considerably more uniform radiation than that of its predecessor.

The next step was to increase still further the area of the anode (see Fig. 4.) The anode now nearly filled the sphere. The result, however, was not so good, tending to show that the best size of anode is something less than Fig. 4, and greater than Fig. 2; but Professor Lodge thinks that this is a question of the particular vacuum employed. Another differently shaped anode was next tried. This was formed of a metallic hemisphere with a flat plate in front of it (see Fig. 5). The idea was to get all, or nearly all, of the electric discharge, and so possibly most of the cathode radiation also, to take place between the outer aluminum hemisphere and the anode. The idea probably is a crooked one; anyhow, this form proved less successful than others. The plate was next removed and the hemisphere was replaced by a larger one, as in Fig. 6. For some unknown reason this form gave no radiation whatever, although the vacuum was fairly high. The resistance, however, was low. The experiment was not really a successful one, for there arose some trouble from either small leakages or vapor pressures. The next form was Fig. 7. This gave really bright flashes on a sensitive screen, and the resistance was low. Still another form is that of Fig. 8. The anode now is a hollow cylinder with one end open. The total area of this anode is considerably greater than that of Fig. 3, but the latter gave much the more powerful radiaton. It appears, therefore, that both the size and the shape of the anode have an important influence on the radiating power of the apparatus.

The form which gave the most powerful radiation was that of Fig. 3. This sent a powerful radiation through three feet of solid timber. The rays on emerging were received on a fluorescent screen made of about fifteen shillings' worth of potassium platino-cyanide, and the area of which was 36 square inches. This screen was considerably affected by the rays after having traversed the three feet of timber, and gave sufficient light to see very small objects in. But the hand,

[1] Nature.

when placed between the screen and the timber, cast no shadow whatever.

The next observation on the power of the radiation was to take the screen to a distance of 30 feet from the source. At this distance the bones of the hand could be seen, but not the flesh. Even the bones cast no deep and sharp shadows at this distance, not owing to lack of fluorescence—for the screen was really bright—but owing probably to the turbidity of the intervening 30 feet of air.

The source was afterward placed in position at one end of the laboratory, and the screen taken to the opposite end, or rather to the end of the corridor leading to the laboratory, a distance of 62 feet from the source. Even here the screen fluoresced with some energy, but the hand was observed to cast no perceptible shadow. When this apparatus was working, there was no place within the large room where the screen did not fluoresce, the rays passing through masses of timber and tables with surprising penetration.

This experimental tube, however, with its rubber joints and ebonite insulation, is not a lasting concern. Although a good vacuum can be maintained for hours together when not in work, it will not last more than half an hour or so when in continuous use, after which more pumping is necessary. The current evidently produces some change in the rubber and ebonite, disengaging a gas which slowly destroys the vacuum.

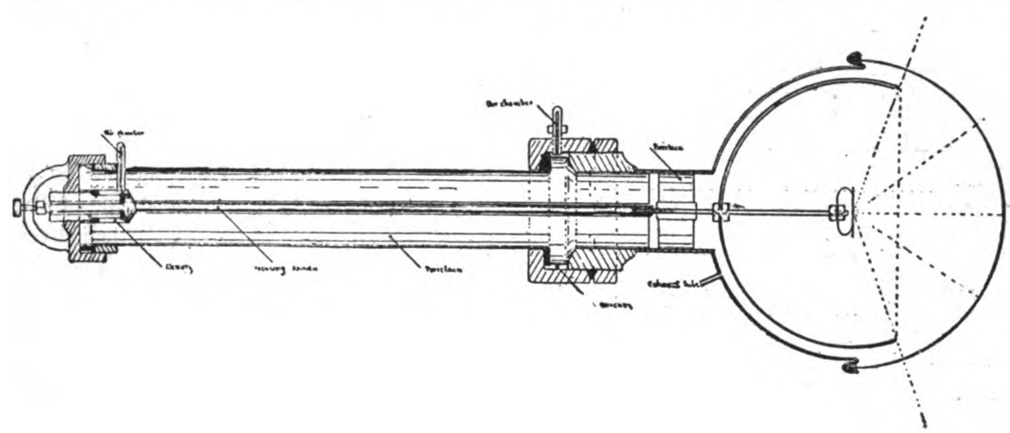


FIG. 9.

In the final instrument the joints are of mercury, and the insulation of porcelain. The joints are first ground and polished and then flooded with mercury. Except the porcelain, the entire apparatus can be made in the lathe, which is a great consideration. A longitudinal section of the instrument is given in Fig. 9. At the end of the porcelain is an arrangement for focusing, which can be manipulated while the instrument is working, so that a point source can be obtained definitely and easily by trial. This figure, which is reproduced from an early picture, has a spherical anode. This should be replaced by a circular plate resembling the anode of Fig. 3.

This last form of instrument, though designed in the middle of May, has not yet been built, owing to the delay in manufacturing the various parts. The parts are easily enough made but manufacturers seldom care to attend to single articles except at their own convenience.

In conclusion it may be stated, though it is unnecessary to do so, that the instrument just described owes its existence to the teaching of Prof. Lodge.

LITERATURE.

LES NOUVEAUTES ELECTRIQUES.—By Julien Lefèvre. Paris, 1896. J. B. Baillière & Co. 412 pp. 5½ x 3¼ in. 157 illustrations. Price, $1.25.

As its title implies, this work treats more particularly of the progress and inventions in the field of electricity which have been accomplished since the Paris Exposition of 1889. In this period, while there have been no new discoveries which have added a new branch to the science such as electric lighting or telephony, there have been a large number of interesting applications of electricity and a wonderful development in several directions. It is with these later developments that the book deals.

The subjects covered include the discoveries by Hertz of electric undulations, the work of Tesla in high-tension alternating currents, the experiments of Ferraris in polyphase currents, and in considerable detail the work of Moissan with the electric furnace.

In addition to these subjects there is devoted quite an extensive description to the progress of electric railway development, central lighting station practice, the Hermite disinfecting process, Röntgen's discovery of the X-rays and a number of the more recent inventions in the electrical field.

The subjects handled are too numerous to admit of more than description and no mathematical treatment is attempted. The book is therefore adapted to the use of the general reader rather than to that of the technical student of electricity.

WESTINGHOUSE ELECTRIC STREET CAR EQUIPMENTS. By F. L. Hutchinson and L. A. Phillips. East Pittsburg, Pa., 1896. Published by the authors. 91 pp. 7 x 4½ inches. 42 illustrations. Price, $1.00.

All electric railway employés should be thoroughly familiar with the apparatus which they handle, and they are generally anxious to learn about the operation of the various electrical devices upon a car; but there has been so far but little literature published which is sufficiently non-technical and simple in its explanations to be of service to the average motorman, to whom this little book is particularly addressed. The authors have endeavored to put all directions, diagrams and illustrations into such form as to be readily understood by any man of ordinary intelligence without previous electrical training. The book treats of the street car equipments manufactured by the Westinghouse Electric & Manufacturing Company and gives directions for the proper inspection and repair of the same, and also explicit instructions for locating and remedying any electrical trouble that may be encountered. The chapters on repairs and on how to locate and remedy faults are of special importance to electric railway men, and the book as a whole will prove a great help to the class of employés to whom it is addressed.

LETTERS TO THE EDITOR.

LIGHTNING ARRESTERS IN THE RAGATZ PLANT.

In The Electrical Engineer, No. 434, I find a description and sketch of a lightning arrester which is attributed to Messrs. Oelschlager-Schrottke. I beg to point out that this form of arrester was used by me several years ago, as may be seen by reference to the London "Engineering" of November 29, 1895, where a description and sketch of it as used in connection with the Ragatz plant will be found on pages 655-6.

Baden, Switzerland, Sept. 7, 1896. C. E. L. BROWN.

CAN AN ELECTRIC CIRCUIT BE OPENED WITHOUT AN ARC?

THE Electrical Engineer of March 18, 1896, has a contribution by Mr. A. J. Wurts, under the above heading. So far I have noticed no response. My answer is, "Yes." It can be done in various ways.

The most convenient method I know of to demonstrate it is to withdraw an electrode through and from a strong solution of the salts of ammonia. In this case the contact is broken among the gas bubbles on the surface; in other words, in an atmosphere that will not support combustion.

For some time past I have expected to bring this theory into practice by using it in connection with my series multiple controller for regulating railway motors.

CONTENTS.

SILVER TO GIVE AWAY.

WE print on another page a most interesting description of the electrolytic copper refining plant, at the Anaconda mines in Montana, this plant being probably the largest of its kind in the world. The processes employed there and elsewhere have added enormously to the quantity of high grade copper made available for the market at low prices, and have had their consequent effect on the electrical trades. But there is another remarkable aspect to the subject, in this year of turbulent national politics. We refer to the nature of the byproducts resulting from the copper refining process. Taking the authoritative figures given for the Anaconda mines, we find them to have a capacity of 200 tons of refined copper per day, but in addition there are given up by the process, which costs only $16 per ton to apply, no less than 350,000 ounces of silver and 1,500 ounces of gold, per month; these precious metals coming in as by-products. Converting these items into dollars and cents, we get, as will be seen, the following figures: Copper, at 10½ cents per pound, $1,260,000 per month output; silver, at 65 cents per ounce, $227,500; gold, at $20 per ounce, $30,000. The Anaconda Mining Company paid a dividend to its stockholders last May of $750,000, and, though we know nothing of its internal affairs, we see no reason on this basis why it should not keep up a good rate of dividend. It is hardly stretching language to say that it has silver to give away.

In view of the enormous bodies of copper ore in sight, and the facility with which it can now obviously be worked to the utmost advantage, can there be any doubt as to the course which the owners of these and similar mines would naturally pursue in the event of the adoption of the silver standard in this country? It is safe to say that such a result at the coming national election as to invite their activity would result in an increase of this indirect silver production of startling magnitude, which, added to the direct production, would in a short time give us a flood of the white metal such as the world has never seen. Regardless of politics, is such a thing to be invited, and if it is to be, what is the use of talking about maintaining national credit, old ratios or raising the price of silver?

The effect on the copper market of such an enormous increase of production can also be well imagined, for, of course, conversely, the copper miner would be able, if he chose, to give away his copper as a by-product, and be handsomely recouped by the silver contained in his ore. We are heartily in favor of anything tending to bring about rational reduction in the price of the materials of construction employed in the electrical arts; but we confess that we would rather see copper back at its old "good times" price, around 20 cents, than note a further reduction on the present low price brought about by a fictitious remonetization whose result would be sheer repudiation in national finance, and would literally tear up every private contract not calling for gold. As an object lesson in the influence of electricity on the value of mineral properties, and the consequent result in bringing about new financial conditions, the Anaconda mines constitute a brilliant example. It is to be borne in mind that electricity elsewhere in mining, by its use of water-powers and by dispensing with the use of costly fuel at lofty altitudes, has brought many low grade mines up to

a basis of profit; and the end is not yet of the use of electric power in such work.

An important detail of the processes employed at Anaconda is the method resorted to for producing the proper toughness in copper required to make good plates, tube and wire in the subsequent working up of the metal in the arts and trades. The Elmore process of subjecting the cathode to a continuous surface-rolling during deposition has not entirely avoided some of the drawbacks to the direct working of the metal as it leaves the electrolytic baths. Among these hindrances, perhaps flaking or foliation of the copper is the most serious. By the application of high pressure jets of electrolyte against the cathode, this defect is now said to be entirely overcome, so that electrolytic copper may be regarded as possessing all the good working properties of the smelted metal and the greater purity in addition. This is one of the improvements to be looked for in the growth of any new process or industry, and in the present case is a decided advance.

CABLES AS POLITICAL LIGHTING CONDUCTORS.

BEFORE leaving Paris Lord Dufferin, the British Minister to France, was given a farewell dinner by the British Chamber of Commerce, at which time he took occasion to refer to the good work done by submarine cables and telegraph wires, in preventing war and in upholding the peace of the world. His attitude was magnanimous, for it is certainly susceptible of proof that electricity has diminished the importance of the diplomatist, by rendering him less important as a go-between and in enabling his principals to get right together quickly. From one point of view, he inclined to regard the telegraph as an element of danger, and said: "Thanks to the telegraph, the globe itself has become a mere bundle of nerves, and the slightest disturbance at any one point of the system sends a portentous tremor through its morbidly sensitive surface. We are told by the poets of old that when Zeus nodded the golden halls of his Olympus shook to their foundations. To-day it would suffice for any one of half a dozen august personages to speak above his breath or unwittingly to raise his little finger, and, like in a heaven overcharged with electricity, the existing conditions of unstable equilibrium which sustains the European political system would be upset, and war, waged in circumstances of greater horror than has been hitherto known to the experience of mankind, might eventually envelop not Europe alone, but two—nay, all the four—continents at once, since in every one of them representatives and offshoots of the contending nations would of necessity be brought into collision."

Perhaps the knowledge that great forces can be set going so instantaneously, by the agency of the telegraph, is itself a check on the ready tongue or hasty temper, if not of the warriors of the daily press, at least of the men who sway the destinies of the nations as rulers and ministers. This, Lord Dufferin admitted, for he went on to say that: "After all, a very thin wire proves a perfectly effective lightning conductor, and for over eighty years, thanks to this unpretending agency, an unbroken peace has been maintained between your native land and the country with whose prosperity and welfare your own interests are so closely associated." In other words, while, as Prince Bismarck once complained, electricity has made diplomacy less "unctuous," it has made it more direct, and has placed the dread responsibilities of peace and war where they belong, not with the diplomat but with his principal, so that they who stir up international strife and try to cultivate prejudices and animosities rather than the comity and amity of nations are known and can be treated accordingly.

LAMP AND SOCKET STANDARDIZATION.

FOR some time past our columns have witnessed the discussion of the subject of standardizing lamp bases and sockets. It is well to have an important subject of this kind agitated, but the discussion is of little use unless it leads to improvement and reform. We are glad to note that President Nicholls, of the National Electric Light Association, has taken the practical step toward settling the question by his letter which appears in this issue. There can be little doubt as to the readiness of the manufacturers to deal effectively with the matter and to reduce confusion to uniformity by the adoption of proper standards. And when the subject of sockets and bases is disposed of—there are others.

ELECTRIC LOCOMOTIVES IN TUNNELS.

IT is said that an official of the Fitchburg Railroad has intimated that at an early day the long Hoosac Tunnel will be worked by means of electric locomotives, just as the Baltimore Tunnel is. Some years ago the electric lighting of the tunnel was accomplished and was considered quite a feat, but the nuisance of the smoke and gas from the steam locomotives remained. The ventilation of the five miles of tunnel would, however, under the new conditions, be vastly improved. As there is abundant water power in the vicinity, the expense of operation should not be large, and the whole train, steam locomotive included, can be picked up at one end of the tunnel and steam shut off until the other end is reached.

People in the Hoosac region are pleased with the news, as well they might be; and we hope the time is not far distant when we shall hear something of similar import in regard to the New York Central Tunnel in this city. That deep cut and hole is a terrible place to go through in summer, and a disagreeable place in any season, and the railroad company would be a gainer, we believe, by enough travel to recoup it for the outlay, if it made the change to electricity.

FIRE PROTECTION OF HIGH BUILDINGS.

AT a recent meeting of the International Association of Fire Engineers, when the question came up of protecting or saving the modern tall office building, the saying was quoted of one fire chief, that they ought to let such buildings burn down to the water reach. This exceedingly cheeky and nonchalant proposition did not meet with general acceptance, nor could it at the hands of any body of progressive men. On the contrary, the opinion was that firemen existed to fight fire and that there were means of getting at a fire even if it was on the top floors of a 150-foot building. For example, attention was called to electric pumps, which could be used at any altitude, and the motors of which could be kept running a long time if necessary. The desirability of keeping the electric light service going was also pointed out, and electric elevators were also noted, the use of an elevator in carrying up a line of hose, instead of dragging it up the stairs being obvious. We have heard recently of one improvement suggested by a fire chief, which consists in having lines of water pipe hidden under the cornices of these tall buildings, the valves to be released electrically at the moment of need, so that flames from outside encounter a complete water sheet which keeps them off.

ELECTRIC LIGHTING.

ELECTRIC LIGHTING IN NEMOTOWN.

BY HARRY N. GARDNER.

FROM week to week The Electrical Engineer presents to its readers descriptions of commercial or isolated lighting plants situated in various parts of the country. As an example of a commercial lighting and power company, the plant and methods of management of the Nemotown Electric Light and Power Company are worthy of brief description, not because of any advanced methods of engineering, or because this plant is particularly different from many others throughout the country, but because a description of no similar plant has before appeared in these pages.[1]

The first noticeable thing which has characterized the management of this company is a careful regard to economy. The Nemotown Electric Light and Power Company is a concern formed by the consolidation of two former rival companies. As it was found more economical to continue using the machinery of the combined companies, not much system in equipment can be expected.

The central station, with some of the interior equipment, was originally the power house of the now defunct first electric railway of Nemotown, bought cheaply by the present owners at sheriff's sale. There have been several additions made to the original structure, built only as the necessity of the time demanded.

The boilers are one 125 horse-power and one 75 horse-power, the original boilers of the railroad company. In their earlier years, these boilers were subjected to very hard treatment, but, with continual repair, it is thought they can be made to do service for several years yet. Besides these, there are one 80 horse-power, two 125 horse-power and a 160 horse-power boilers, which were used by the companies before their consolidation. These, together with one almost new 200 horse-power boiler, complete the boiler equipment.

Originally the coal was stored at one end of the present boiler room; but the installation of additional boilers made it necessary to build a coal room. As the company did not own the land in front, the coal room was built at the rear of the boiler house. The coal is easily shovelled into this room from wagons, and, when needed, the firemen as easily wheel it around to the furnace in wheelbarrows. The same wheelbarrows are also used to convey the ashes to the dump, some distance away.

In the engine and dynamo room is one 300 horse-power Corliss type engine, belted to a jack shaft, to which several dynamos are connected by means of clutch pulleys. Two 80 horse-power and two 100 horse-power slow speed simple engines are connected to another jack shaft, to which the dynamos are connected as before by clutch pulleys. Fixed pulleys connect the engines to the shaft. One of the engines is held in reserve and in case of emergency it can readily be thrown into use by shutting down the others for ten or fifteen minutes, to take off and put on belts. Besides these, there is a 250 horse-power tandem compound high speed engine.

The steam pressure varies from 80 to 110 pounds. As indicators are a needless expense, and take so much of an engineer's time to attend to the readings, the company has never bothered with them. Besides, they have never had an engineer who understood taking indicator readings. It will, therefore, be impossible to give any data concerning economy of engine working.

The 250 horse-power engine is belted directly to a 100 kilowatt, 500 volt power generator and a 120 kilowatt, two-phase Stanley alternator. The other dynamos consist of three old Van Depoele machines, the power generators of the former railroad company, upon which an enterprising "electrician" spent several hundred dollars in trying to rewind them for arc machines (these dynamos are not now in use); two 40-light and one 50-light Brush; one 30-light and two 50-light Thomson-Houston and one 80-light Fort Wayne arc dynamos; and four alternators from 650 to 1,200 lighters, two of which are Thomson-Houston, one Westinghouse and one Slattery.

The switches and instruments are mounted either upon the two panel marble board, or the wooden board beside it, placed at one side of the room.

From the central station the wires are carried to the various parts of town upon poles. It has been found that the strain upon the poles is less (making it unnecessary to set the poles so deeply in the ground) if the wires are not drawn very tight; and upon street corners, where several wires cross each other, it is often impossible to separate them very far. Of course, winds often cause the swaying wires to become crossed; and upon damp nights it may happen that the crossing of two wires produces an arc light for which the city has not contracted, but the company generously refrain from charging for it.

With the combination of the two systems, several years ago, naturally several of the circuits became useless; but as it is unknown when these lines may again be of service, the dead wires have never been taken down.

The transformers, like the station machines, are of several makes, and are for both 52 and 104 volt secondaries. In most cases they are of rather small size. In fact, this company has proved the fallacy of the idea that larger transformers should be used wherever possible; for if a transformer accidentally burns out, with a small one fewer customers are left in darkness, and it is so much easier to replace the small one in such a case. As to the economical advantage of the larger, what difference can there be? If no lights are burning, how is there any current loss?

In most cases it has been found convenient to place the transformer upon the buildings. For residences, a transformer is a decided ornament. If the wiremen can be induced to bring the wires out at the front, so that the transformer can be placed in a front gable, the ornamental effect is greatly increased. Of course,, the tenant may object; but it is easy to "bluff him out" by telling him it has to be put there in order that he may have lights.

In the business portion of town, not only are the transformers placed upon the blocks, but in most cases it has been more convenient to run the secondaries along the front of blocks upon knobs or rubber-hook service blocks. In some cases labor may be saved by running the primary wires from one transformer to another in this way.

Many of the customers have taken out their lights during the last four or five years. But as no one knows how soon the dead wires may come handy, they are never removed. Even where the transformers are taken down, the wooden transformer blocks are left, with the untaped ends of the primaries still attached. If any one should be careless enough to come in contact with these wires, it would probably teach others to be more careful of the "juice." The effect of this system is very pleasing to the critical eye. Thousands of dollars spent in architectural ornamentation could not produce the effect which this company furnishes free of charge.

The underwriters are beginning to object to many things in connection with this system; but insurance inspectors are "a lot of cranks, appointed only to make trouble," and they have to be "stood off" as long as possible. Besides, if the insurance people can be forced to "make a big noise" about the danger, in striving to effect a change, it is so much free advertising, and will greatly increase the condfience of the public in the use of electricity.

The calculation for the service lines is left entirely with the lineman. A conversation recently overheard will serve to illustrate the studious care bestowed upon such calculations. Two linemen were connecting up a residence. In this case the house-owner had objected so strongly to placing the transformer upon the house, it had been necessary to put it upon a pole. The lineman up the pole had asked his companion to send up some wire for the secondaries.

"What size d'ye want, Bill?" was the inquiry.

"Oh, there's a lot of lights in there; better have some number six."

A moment later the other called from the wagon where he was searching: "Ha'int got 'nough six, Bill, here's some number four."

"That's too hard to splice with. Ha'int there some number eight?"

"Nope! Here's 'nough number ten."

"Well, let's have that. Guess that's good enough."

After he had attached the wire to the handline, the man upon the ground called, "Splice them on and come on down. I'm goin' round to Murphy's place for awhile, before we tap in them primaries."

In some cities it is thought necessary to test out a transformer before it is put up. But this company saves the valuable time which others might waste in this manner. A few weeks ago the service in a residence was discontinued on account of trouble caused by grounded wires. A short time after the transformer taken from there was used upon a business street. The next morning the lineman who went to find out the trouble reported from that place, learned that in attempting to turn on lights the night before, one man had been knocked down and another thrown across the room. Had there been worse grounds upon the outside lines, so that the

[1]The details here given are all based on actual observation. With a few changes in name and style of apparatus, the features of central station equipment, as well as the pole and line construction, and business methods, could be shown in different towns.—Author.

men had been killed, the lineman would have learned just as easily that the primary and secondary of the transformer were crossed.

Another way in which some companies waste much time and material is in soldering all joints. This needless expense is all saved by the Nemotown Electric Light and Power Company, for it has been decided that this talk about the resistance loss of unsoldered joints is all "fol-de-rol."

It has also been found much pleasanter for the telephone linemen, or others who may have to climb the poles, if the joints of primaries are occasionally left untaped.

Some companies have considerable time and material wasted in attempting to avoid open circuits upon arc light lines, by taking extra precaution in tying leg wires, reinforcing the wire at certain points, and in other like precautions. The foolishness of such methods is proved by this company, who find that two men can have considerable time to hang around saloons, besides the time they spend in search of open circuits. Besides, it is better to have the lights upon an entire circuit out for a night occasionally, in order that the people may more fully appreciate the advantages of electric street lighting.

Both the contract and meter systems are used for the incandescent and power service; but it has been found impossible to charge a uniform rate in either case. It has been known to afford the deepest satisfaction to a customer to learn that he is paying a dollar a month for the same service for which his neighbor pays fifty cents. It also pleases a house-owner, who was compelled to have a meter put in, to learn that the alderman living next door is able to dispense with this luxury.

It has been found unnecessary to test meters more than to be sure that they register enough. If the meter runs fast enough, the customer is sure to be satisfied. His satisfaction may take the form of objection, when he thinks his bills are too high. But people must have something to "kick" about; if it is not their bills, it is about the unsteadiness of the light. It is known that it greatly shortens the life of lamps to occasionally change the voltage upon the lines. As the company charges for all lamp renewals, this method adds considerably to the revenue in the profit from lamp sales.

Several novel methods of advertising have been inaugurated. One of these consists in using a very small service wire for one part of town, so that during the "heavy load" part of the evening, old lamps give as much as eight or ten candle-power, while the customer only expects sixteen candles. The comparison between a store lighted with these lamps and the one next door, where "Welsbachs" are used, cannot help advertising electricity.

Another fallacy still believed in by some companies, which the experience of this company has disproved, is that it is necessary to have a man who has had some previous electrical or engineering training or experience to manage such a plant. The very efficient superintendent and general manager of this company is a man who had previously demonstrated his ability for such a position by his successful manipulation of ward caucuses, and was chosen for the place because of his "pull" with the political "boss of the party," one of the chief directors of the company. The value of his services at times, when a new street lighting contract is to be secured, because of his "influence" with the aldermen, cannot be estimated.

In the successful operation of the business, he is aided by a carefully selected corps of assistants, each of whom has demonstrated his ability for the position he holds by always voting the right ticket upon election day.

The success of the company has been so great, it is thought the official board can soon support another official, and it is rumored that as soon as the creditors can agree upon a man the company is to have a receiver.

THE SPECTRUM OF REFLECTION AND THE EFFICIENT ILLUMINATION OF CONFINED SPACE.—I.

BY DR. W. H. BIRCHMORE.

THAT colors within a confined space, for example, a room whose walls are covered with a paper of a given hue, are better illuminated and defined by the light of the sun than by any amount of artificial light, no matter what the source, is a fact within the experience of every person; but the laws which may be said to govern the modifications of the various colors by the light of heated carbon have been but little studied and are hardly so well understood the they can be made of any practical value in daily life.

When luminosity is discussed attention is directed almost exclusively to the emission of light, regardless of the part of the spectrum into which such emission falls, while the reaction of the surfaces upon which the light falls, and modification which the light undergoes by such reaction is quite too much neglected.

Doubtless the data are difficult to obtain, but so are really valuable data in other subjects, yet the game is well worth the candle. To determine satisfactorily the reason why with so great an increase in the emission of light our lamps seem to make darkness visible rather than the objects in it seems to be worth all the enormous expenditure of time and trouble it seems destined to cost. The proper execution of the task implies the careful study of many hundred spectra and most careful comparison of the results, not only of one series of studies but of many, for in this way only can the personal equations of men and instruments be eliminated.

In the issue of The Electrical Engineer for January 1, 1896, was published a contribution on this problem, the further elucidation of which this contribution is intended to advance. In this mentioned contribution stress was laid on the great difference in the lights of the sun and those lamps which use heated carbon as a source of light, and the uselessness of trying to increase the luminosity for the red end of the spectrum by increasing the number of rays in the blue was specially commented on. Since then it has been my good fortune to obtain a large amount of new data, much of it quite unique, and from this data to advance the study, I believe, a number of steps.

In the contribution mentioned, reference to and quotations from the extensive study by Meyer into the number (proportionate) of the rays in different parts of the spectrum were freely made, and the composition of certain lights investigated by him was made the basis of the argument. This composition table is as follows, except that the emission of light nearer the "D" lines is made 100 instead of unity in order to be rid of decimal fractions.

COMPOSITION OF SUNDRY LIGHTS PER UNIT OF "D"-LINE LIGHT (Meyer).

Region of Spectrum.	"B."	"D."	"E."	"G."
Sun	407	100	43	15
Day	125	100	50	41
Arc	110	100	40	10
Oil Lamp	66	100	140	100
Carbon Filament	30	100	140	110

These reduced to percentages of the total emission are:

	"B." orange.	"D." yellow.	"E." green.	"G." violet.
Sun	72.0	17.7	7.6	2.7
Day	39.5	31.6	15.9	13.0
Arc	42.3	38.5	15.3	3.9
Oil Lamp	16.2	24.6	34.5	24.6
Electric Incandescent	8.0	26.3	36.8	28.9

From these numerical values the great excess of violet and green rays over those of the other end of the spectrum in carbon lights is very manifest. There exists, moreover, a relation which may very truly be called selective, by which a surface makes choice of the rays it will reflect quite apart from those which the illuminating source emits.

If the power of reflecting light of any given wave length possessed by any surface is made the subject of investigation a numerical value in terms of an arbitrary unit may be obtained, which from analogy to its fellow function may be called the index of reflection. After much study a method was devised which is very simple and eliminates entirely the question of the absolute value of the standard lamps. This index expresses the comparative amount of light of any given wave length reflected from a surface in terms of the amount reflected from another surface used as a standard.

In my studies I have made use of a plate glass mirror as the unit surface. This is the most satisfactory surface available for the purposes of the work contempleted, as it is one readily reached and makes possible the verification of the work I have already done and its construction in other hands.

During the last six months studies have been made to establish the reflecting indices of a number of surfaces of a variety of smoothness and color, and the reflection indices of these surfaces for light in the vicinity of the principal lines of the spectrum have been carefully investigated. About one hundred surfaces have been studied, including cards, wallpapers, drawing papers and the like. These were variously colored, the wallpapers were usually body colored, not printed; the cards were principally approximations to the real colors of the spectrum, while the drawing papers were washed sometimes with anilins in "water megilp" and sometimes with the colors from my color box. The conditions present very soon divided the whole mass into two series, one of smooth and the other of rough surfaces, the smooth surfaces reflecting a continuous spectrum quite apart from the color which they presented to the eye. Thus, a very highly finished card colored red reflected more violet light than a piece of rough paper covered with a wash of manganese violet. In nearly all cases the surface

spectrum, however faint, was continuous, so that no little care was required to be sure that confusion was not given the place intended for order. Incidentally, it was also made clear how little of an excess in the reflection of any ray group produced a distinct hue.

To illustrate this matter by an experience in practical life the following series of indices are chosen for discussion: They are those of the wallpapers in the rooms about me, and are such as an architect would be likely to choose for decorative purposes on the walls of any well finished house. They are all solid colored papers, and are none of them of very smooth surface, and are commercially known as ingrain cartridge papers. The indices are given for those wave lengths only for which the Meyer's equivalents were at hand. These indices were obtained as follows: Two lamps of widely different candle-power were arranged, so that the light of the larger would fall upon a mirror and be reflected into the slit of the spectroscope, and that of the smaller one upon the comparison prisms and be thrown into the slit. An equality of reflection was previously ascertained by rigorous experiment, or rather it was shown by rigorous experiment, that the difference in the two reflections was too small to be observed. Observations were made in various parts of the spectrum and the distances from the slit at which the illumination was equal were accurately measured. The intensity of the lights would then be reciprocally as the square of these distances, and could be represented by the ordinary equations. If now a surface were substituted for the mirror a new relation would be established and by combining these two equations one was obtained from which the reflection index of the light under observation for that surface could be readily calculated. As this method required only linear measures, it was the most simple, and as the instruments used were of the very best, it followed that the results were prima-facie to be relied upon, but when time and again checks were obtained which made the possibility of an error quite of the smallest, absolute confidence and finally almost scientific certainty in the accuracy seemed possible.

REFLECTION INDICES OF FOUR SAMPLES OF WALL-PAPER.

Sample.	A.	B.	C.	D.
"B." rays, orange	0.00095	0.00036	0.00210	0.00214
"D." rays, yellow	0.00067	0.00036	0.00140	0.00272
"E." rays, green	0.00039	0.00048	0.00120	0.00089
"G." rays, violet	0.00028	0.00028	0.00028	0.00028

If these indices be multiplied into the numerical values given in the table for the percentage composition of light, and this product by 1,000,000 to get rid of the decimals, the following numerical values are reached:

NUMBER OF LIGHT RAYS PER MILLION INCIDENT REFLECTED.

Sample.	A.	B.	C.	D.
	(Sunlight.)			
"B." rays, orange	684.0	259.2	1,512.0	1,540.8
"D." rays, yellow	189.6	63.7	247.8	481.4
"E." rays, green	29.6	36.5	91.2	67.6
"G." rays, violet	7.6	7.6	7.6	7.6
	(Electric Light.)			
"B." rays, orange	76.0	28.8	168.0	171.2
"D." rays, yellow	176.2	94.7	368.2	715.3
"E." rays, green	143.5	176.6	441.6	327.5
"G." rays, violet	81.0	81.0	81.0	81.0

These numerical values represent the number of rays of the given wave length reflected from the paper for each million of the given wave length incident thereon.

If it is assumed that the number of wave lengths represents a linear scale, and it lawfully may, then the comparative total reflections from the papers will be expressed numerically as follows, quite regardless of the actual number of rays which may be supposed to represent the ether-impulse:

Sample.	A.	B.	C.	D.
Sunlight	51,143	20,839	237,900	268,800
Incandescent Electric	34,110	27,599	135,424	165,888

These values have been applied in a number of rays to the solution of problems, the results afterward tested by experiments with instruments of precision and the qualities given are unquestionably near enough to be used for practical every-day work. The method is quite arbitrary in conception and in application, yet the results obtained seem to form a rational basis on which to predicate a choice of wall papers and other finishings for rooms in which definite color schemes are to be preserved when artificial light is used.

Of these papers, A, C, and D, are "yellow-red" papers, while B is a "blue-green." The colors used in them all appear to be the same pigments. The basis is a yellow ochre, to which is added raw sienna in case D and red ochre in case A. Prussian blue is added in B. Making imitations on white drawing paper I have been able to reproduce the color schemes of the papers and to check my resulting reflection indices within a very narrow margin. The regularity with which these results can be obtained is an interesting proof that the surface reflection can be eliminated by study and the surface illumination and the color illumination treated separately.

How enormous is the excess of sunlight reflected no words are needed to show, but much more worthy is the part of the spectrum into which the reflection falls. While the sunlight reflection is distinctly orange in its preponderating tone that from the carbon illumination is distinctly a blue-green. Since our notions of color are all formed by the day (sun) light experience, it is manifest that the changed light relations must produce very different color impressions, and daily experience shows that they do.

Curiously enough the changes are toward that common maximum which we call white; yellow is "whitened" by the excessive blue-green, while blue-green is "whitened" by the excessive yellow. In other words, "hypo-chromatic white" is the result. That blue-green rays shining upon a body which has a yellow tinge by sunlight tends to whiten it, is a matter daily observed, but rarely commented on in school experiments and hardly mentioned in school books. Reference is made in Ganot's Physics to the fact that when blue and yellow pigments are mixed green is produced. For example, the water color green pigment called "Hooker's Green" is a mixture of prussian blue and gamboge, and it is also carefully illustrated that when spectral yellow and spectral blue are mixed "white is formed," but there are no deductions made at all commensurate with the importance of the facts in the case. The truth of the matter is that if the entire rays-group from "D" to "G" be added in certain proportions they produce a mean sensation for all colors (pigments) by reflection from which the color sensation disappears, only form sensation remaining, and this also will fail if the contrast of sensation is reduced far enough. Yet this light is ortho-chromatic for certain peculiar tints which reflect no red.

It is important and should be remembered that the common notion that the color we call white reflects all the rays which fall on it in same proportion as they fall, is simply a mistake. The purest white that I have been able to obtain, pure barium sulphate, reflects red much less readily than yellow, and the paper on which this magazine is printed owes its peculiar hue entirely to a small difference in its power of reflecting blue-green, a deficiency as compared with barium sulphate, and n t to any excess in a yellow or orange reflection as compared with the same standard. It will be noticed immediately that in Sample B (a blue-green paper), the number of rays reflected per million incident is decidedly greater by the light of heated carbon than by that of the sun. It is also seen that the amount of violet reflection is greatly increased in all four cases. It is very evident that no augmentation in quantity, that is, candle-power of incandescent illumination, will ever bring out the natural color, the sunlit hue, of objects. In Sample A the carbon light gives no hint of an orange hue, while the yellow is so increased and then neutralized by the blue-green that a solid ivory color results. B really belongs among the "Peacock tints," and so much is the color changed by the carbon light that it is almost sea green in hue.

While the papers thus change, an exactly equivalent tone change, either by contrast or complement, takes place in every color in the room; the warm tones are made gray, while grays are changed to blues and to greens.

At first sight it might be inferred that this evil case could be avoided by using only those colors in which yellow-green and violet are in excess, or by using some form of light other than that of heated carbon, but such solutions do not meet the case at all; the trouble is in the spectral value of all our present artifical lights; improvement can come only by improving the amount of light emitted at the red end.

The idea that a piece of green silk would be more green and less gray by added orange when illuminated by the heated carbon light, seems bizarre, but it is simply the fact.

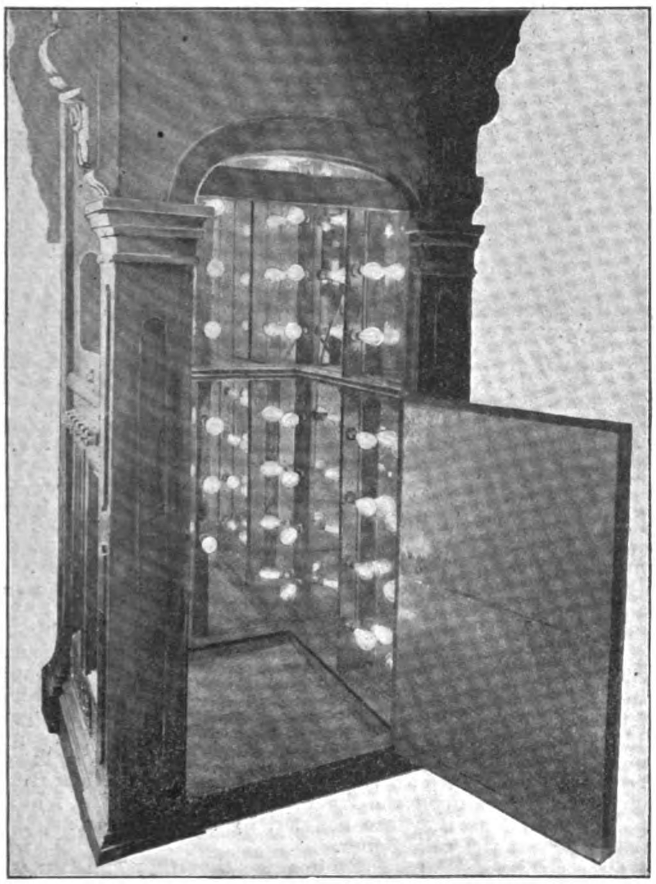
The needed improvement in our lamps is not increased emission, but an emission of different wave length from the present one. Surely it is not in vain that an appeal for a heatable material whose radiation will be of the wave length desired is made to such a race of inventors as this American race has always proved itself to be.

THE WALLKILL VALLEY ELECTRIC LIGHT AND POWER COMPANY have recently purchased a 16 x 36 Corliss engine and have closed a contract with the Fort Wayne Electric Company for a 75 kilowatt alternator. The company is in the market for electrical equipment of any sort. Address A. J. Fowler, secretary.

THERAPEUTICS.

THE INCANDESCENT ELECTRIC LIGHT OR RADIANT HEAT BATH.

THE influence of the electric light on the growth of vegetation and living organisms is now a matter of common knowledge, Sir William Siemens having as far back as 1880 first called general attention to the stimulating effect of the rays from arc lamps. Later experimenters have confirmed these results, but it has only been comparatively recently that the subject has been taken up seriously with a view to its application in medicine as a therapeutic agent. This work has



THE KELLOGG ELECTRIC BATH CABINET.

been carried forward to a remarkable extent by Dr. J. H. Kellogg, superintendent of the Battle Creek, Mich., Sanitarium, a famous Western health resort, at which place the electric light, or, more properly speaking, the radiant heat bath, is now in extensive and highly successful use for a variety of ailments, as a substitute for the Turkish, Russian, vapor and hot air baths, previously employed. The results of extended and accurate tests have shown that the radiant heat bath acts to increase the elimination of carbonic acid gas expired, while it decreases the amount of urea, total chlorides and total solids in the urine.

The accompanying engraving shows one form, the upright cabinet type, of bath employed by Dr. Kellogg. This consists of a cabinet about eight feet in height containing about sixty incandescent lamps arranged in rows, the spaces between the lamps being filled with silvered glass. The cabinet is freely ventilated, and by means of switches the number of lamps can be varied at will. Other forms of bath for special application to spine, legs and feet, trunk, etc., are also in use.

The peculiar value of the electric light bath Dr. Kellogg considers due to its efficiency as a source of radiant energy. In this respect it differs radically from the Turkish or Russian baths, in which heat is brought to the body by convection of air only. Air, being a poor conductor, communicates heat to the body very slowly. Absorption of heat is further hindered by the skin, an excellent non-conductor, and by the rapid evaporation of moisture on the skin, which latter action cools the body rapidly. The heat from the incandescent lamps, on the contrary, is of the radiant form and penetrates the skin and tissues much in the same way as the light rays from the same source pass through the tissues and cause them to appear translucent.

As confirming the correctness of the above assumptions, it may be stated that with the incandescent lamp bath, the time required to induce perspiration was 3 minutes 32 seconds, while the average temperature within the cabinet was only 81 degrees Fahrenheit. With the Turkish and Russian baths the time required was respectively 5½ and 6 minutes, while the temperatures were 128 and 101 respectively.

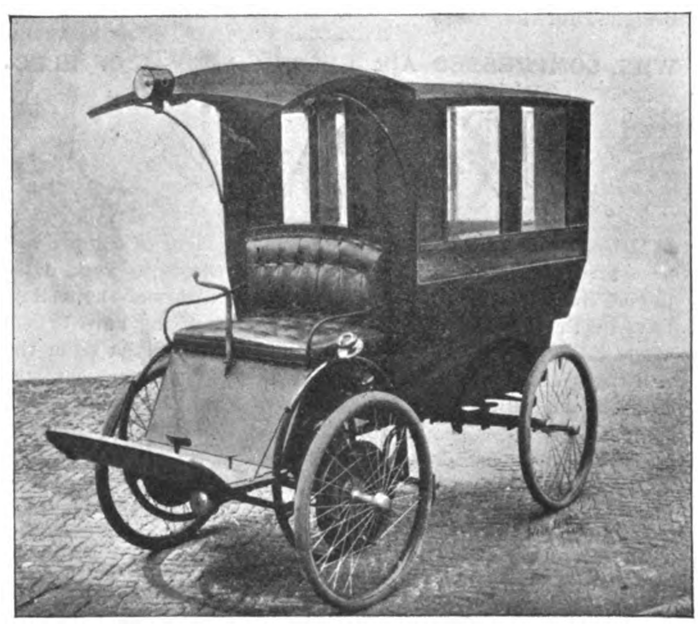
Dr Kellogg has found the electric light bath, upon which he has taken out a patent, of far greater value in the treatment of a great variety of maladies than any other means of applying heat, except water, and believes that it may be much more generally employed than the Turkish, Russian, vapor or hot air baths. The degree of heat can also be regulated with the greatest nicety, a matter of considerable difficulty with the other forms of bath.

ELECTRIC TRANSPORTATION.

THE MORRIS & SALOM ELECTRIC CARRIAGES AND WAGONS.

AMONG the vehicles which took part in the recent motorcycle contest at Providence was one built by Messrs. Morris & Salom, of Philadelphia, which won the distinction of making the best speed thus far recorded for this class of conveyances. This was during the last of the three heats, when the Morris & Salom motorcycle made the extraordinary time of 11 min. 27 sec. for five miles, or at the rate of twenty-six miles per hour, the average time for the five miles being 2 min. 17.4 sec. per mile.

It is of considerable interest to observe that this record was made with two 1½ horse-power Lundell motors as against the



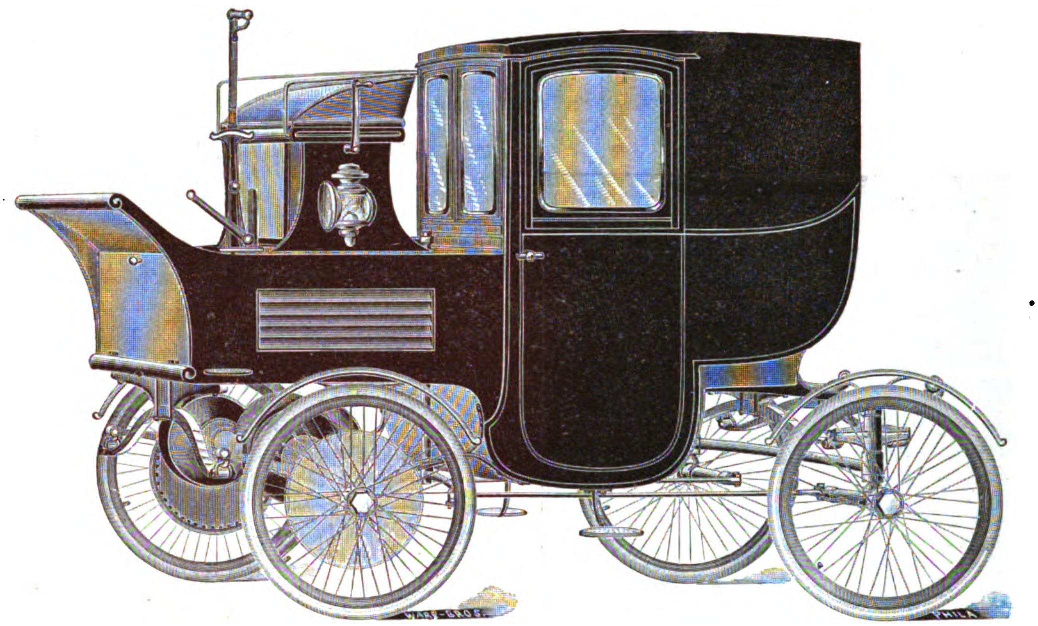
THE MORRIS & SALOM ELECTRIC DELIVERY WAGON.

5 brake horse-power engines on the gasoline-driven vehicles entered in the same contest, which, it is understood, can be worked up to 10 horse-power. Messrs. Morris & Salom, whose work in this field dates back several years, are more than ever convinced of the commercial possibilities of the electric motorcycle. They are not attempting at present to fill individual orders for carriages in various parts of the country, as they consider such a scheme impracticable, but are confining their attention to building a number of electric hansoms and coupés for public service either in New York City or Philadelphia, types of which are illustrated in the accompanying engravings. When they have demonstrated the commercial success of a system of this kind, it will, they assert, be an easy matter to establish stations in every large city in the

Union where a private individual who desires a carriage can have it properly charged and cared for.

These various vehicles will have a capacity of twenty-five or thirty miles on one charge, over ordinary city streets and roads, and the cost of operating, when power is supplied by the owner and not from a central station, will not be more than fifty cents per day, including renewals of batteries and necessary repairs on the vehicle.

The carriages are each supplied with two 1½ horse-power Lundell motors and forty-four chloride cells of a special type designed for this work.



THE MORRIS & SALOM ELECTRIC COUPE.

WILL COMPRESSED AIR BECOME A RIVAL OF ELECTRICITY IN THE RAILWAY FIELD?

Wm. Baxter, Jr.

THOSE who are interested in the development of compressed air motor cars, as well as some of the New York daily papers that have been the strongest antagonizers of the trolley, have for the past two or three months been working hard to convince the world that electricity will soon be driven from the railway field. From the hour when the experimental car was first started, on the 125th street line, in New York, it has been claimed by these people to be a complete success; but the mere fact that the car will run is no proof that it is even partially successful, much less that it is superior to the trolley cars. If compressed air cars can meet with success anywhere, they certainly will in this city; and especially on the road where the experiment is now being tried. The traffic on this line is only moderately heavy, and the grades and curves are almost insignificant; therefore, the maximum effort, as well as the average power required to propel the car must be very low, and this is a great advantage for a car that is run by stored energy.

The promoters of the compressed air system have endeavored to prove its value by making numerous claims that a proper investigation will show are not well founded; and those who have undertaken to show that the electric system is in no danger of being driven from the field, have, in most cases, failed to detect the weakest points of their opponents.

The claims put forth by the compressed air advocates are that the system is still young but that when it has had as much money and brains spent upon it as the electric, it will be in undisputed possession of the field; that with it the strain on the track is very much reduced, and that on that account the ordinary horse car tracks can be used; and, lastly, that no trolley line is required, and that each car is independent of all the others.

The claim that the compressed air system is still young, is not correct, except in so far as it refers to the present experiment; it has been in use for many years, and whether it has had as much money spent upon it as the electric, or not, it is certain that it has occupied the attention of many of the most able engineers of the world, from a time that antedates the advent of the electric motor by a large portion of a century. It may be claimed that its use has been confined to other fields than that of railways, and that on this account it has not advanced much in the latter, but perfection is as essential in other fields as in the railway, and any improvements made in these would be of corresponding value in the latter. It is not true, however, that it is new in the railway field. It was tried before the days of electricity and at numerous times since then, but it has always failed.

The claim that the strain on the track will be less with compressed air cars has no foundation to stand upon, and is based wholly upon the fact that the first trolley cars were equipped with very heavy motors, so mounted that more than one-half of the weight rested upon the axle. The cars of to-day are provided with motors that weigh about 1,500 pounds each, and so suspended that all, or nearly all, the weight is taken off the axle. Compressed air cars cannot do more than this; therefore, their effect upon the track, weight for weight, will be the same, and as they are heavier, by about two tons, they will wear out the rail sooner.

If the compressed air people imagine that they can run cars on the ordinary horse car tracks, they are doomed to disappointment, as they will find out in time. The rails used on those roads are not any heavier than is necessary for the light weight cars used on them, when run at a low velocity, and even if the weight were not increased, the roads would soon give out if the speed were increased to that of trolley roads. If the weight were made three times as great, and the speed were at the same time increased, how could the tracks be expected to last, when they are hardly substantial enough for the present work, as is demonstrated by the fact that very few of them are in fit condition for cars to run on at the speed adopted on electric roads.

The assumption that doing away with the trolley line is a great advantage is in part justifiable, but the gain would not be anything like as much as would appear at a first glance. The cost of the line, and the maintenance thereof, would in all probability be offset nearly, if not wholly, by the increased cost of the compressed air station equipment, and the greater expenditure for repairs.

The compressed air advocates say, that the fact that the cars have to be recharged is no objection, because the operation only requires a few minutes, and that locomotives have to stop to take on water and coal; but they should remember that they are not competing with locomotives, but with electric cars, and these do not have to stop for such purposes. It is claimed that it only requires six or seven minutes to recharge a car; but if the time lost in switching, from the main line at the charging point and back, is included, the six or seven minutes may become ten or fifteen, and in the course of a day these losses would run up to a formidable amount of time.

The defenders of electricity have, generally, taken the view that the efficiency in the conversion of energy is the all-important factor, and that all that is necessary is to show that electricity is superior in this respect. This view, however, is not wholly correct; efficiency is one of the factors that determine the relative merits of the two systems, but it is not the only one, and perhaps not the most important one. The reliability of operation, the cost of repairs, the frequency of breakdowns and the ability to meet the requirements under all conditions of load, are points of fully as much importance as the cost of power delivered at the axle.

As to reliability of operation, it cannot be expected that the compressed air cars will do any better than locomotives would, in the same class of service, and, certainly, they will not do as well, unless equal in design and construction. Locomotives are reliable on steam roads where the rails are high above the ground, and the mechanism can be kept clean, but in all the attempts that have been made to use steam for street car work, one of the greatest difficulties encountered has been the rapid destruction of the moving parts on account of their being constantly covered with mud and grit. The reliability of a locomotive is due not altogether to the fact that it runs on a track where it can be kept clean, but also because the distance covered in a single run is short, and it is then thoroughly cleaned and examined before being used again. The motors of a trolley car are never cleaned, in the sense in which a locomotive is, and instead of making short runs, are kept in service from eighteen to twenty hours per day. If compressed air cars are run under these conditions, they will surely break down very frequently, unless they are far more perfect than locomotives in their construction, and this is not at all probable. It is reasonable, therefore, to assume that unless more time, which means more money, is spent on the compressed air cars they will give out oftener, and, therefore, will not be as reliable. The cost of repairs must necessarily be greater, inasmuch as the parts that wear out are more costly.

One of the peculiarities of electric cars that has had much to do with making them a complete success is the fact that they cannot be stalled by any amount of load, they may be called upon to carry. This much may also be said of the compressed air motors, providing they are called upon to make a great effort of short duration, but if the time is prolonged, the supply of compressed air will be rapidly reduced, and the reserve capacity may be exhausted before the charging station is reached.

It is very probable that compressed air motors can be made sufficiently perfect to gain a foothold in places where the trolley is not allowed, but to compete successfully with it, they must be as capable of withstanding hard usage, and as reliable in their operation under all conditions. In addition to this, the total cost of plant must at least not be any greater, neither must the cost of repairs, and to this we may add that the cost of energy per passenger mile must not be any greater. As the cars are heavier, the energy consumption, and, therefore, cost, per unit of revenue-earning load carried; can only be reduced to the standard of the electric system through a higher efficiency, and it is difficult to show that the efficiency is equal, much less higher. Unless the efficiency is as high, the capacity of the station will have to be greater, and hence, the cost of equipment more, assuming the compressors to cost the same as the generators for equal capacity, but they will very likely cost more. The car equipments will also probably cost more, and the excess of cost in station and car equipment will probably equal the cost of trolley line.

In the cost of plant, therefore, there appears to be but little room for gain. The cost of maintenance would certainly be greater, and as there is very little doubt as to the efficiency being lower, the operating expenses would be greater.

If all the foregoing is true, compressed air has very little upon which to hang its hopes of becoming a successful competitor of the trolley.

THE BRAKE HANDLE BAROMETER.

"This rain is about over," said a motorman on one of the open cars yesterday afternoon.

"Are you a weather prophet?" was asked.

"I think I am, as far as dry or wet weather is concerned," he replied. "I can tell whether we'll have rain within twenty-four hours or not.

"How am I able to do it? Well, it's like this: When it's going to rain the brake-handle becomes sticky almost a day before. The motorman will first notice it fully twenty hours before the storm arrives. You can just barely notice it then, but the stickiness will increase until it will be almost impossible to get a decent grip without tearing the flesh on your hands. Now, on Friday night, I began to feel that sticky business, and I told a fellow who was on the seat behind me that it was going to rain. The sky was clear and after he glanced around he said that I was away off. I said, 'I don't say it's going to rain right away, but it will before this time to-morrow,' and it did. Oh, there's no going back on the brake as a barometer."

At this point in the motorman's remarks a passenger boarded the car. The front seat was about filled, but that did not matter. He wanted to talk with the motorman.

"Is the rain all over?" was his query.

"Pretty near," answered the electricity pusher.

"Well, I'm glad of that. Do you know," continued the latest arrival, "I place more confidence in a motorman's prediction than I do in those made by the weather signal man?"

The motorman blushed becomingly.—Albany (N. Y.) "Argus."

A LINEMAN'S LAP was the post selected at Hoboken last week by a woman who wanted to stop him from digging a trolley pole hole in front of her house. She stayed in his lap very comfortably for an hour, to the intense delight of the crowds. What the man said is not recorded.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The first meeting of the season was held at 12 West Thirty-first street, New York, Sept. 23, at which President Louis Duncan delivered a very able and interesting inaugural address, the subject being the "Present Status of the Transmission and Distribution of Electrical Energy." Messrs. Steinmetz, Wolcott, Lamb, Perry, White, Ries and others took part in the discussion.

At the meeting of the Executive Committee in the afternoon the following Associate Members were elected: H. G. Brinckerhoff, Electrical Engineer, Metropolitan West Side Elevated R. R., 258 Franklin street, Chicago, Ill.; H. G. Meadows, Associate Engineer (Elec.) with Newcomb Carlton, 109 White Building, residence, 114 West Chippewa street, Buffalo, N. Y.; F. J. Newbury, Manager Insulated Wire Dept. John A. Roebling's Sons' Company, Trenton, N. J.; Julio Pinkas, Director General, State Telegraphs and Telephones, Sucre, Bolivia; C. W. Richards, Partner, Cumner-Richards Company, 69 Broad street, Boston, residence, Needham, Mass.; C. G. White, Public Schools Supt., and Instructor in Physics and Chemistry, Lake Linden, Mich.

SOCIETY OF ARTS PRIZE ESSAYS.

Notice is given in the current number of the "Journal of the Society of Arts," London, of two prizes offered by the society. One is the "Fothergill" of £25 and a silver medal, for a paper on "the best means of effectually preventing the leakage of current to earth in electrical installations from generating heat and setting buildings on fire." The paper should consist of about eight thousand words, and be written with a view to being read and discussed at an ordinary meeting of the society. Papers submitted for the prize must reach the secretary by October 1 of this year. Each paper must be typewritten, and bear a motto, the name of the writer being inclosed in a sealed envelope, with a similar motto. The other prize announced is a gold medal and the sum of £20, and is to be bestowed, under the terms of the Benjamin Shaw Trust, "for any discovery, invention, or newly devised method for obviating or materially diminishing any risk to life, limb or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means." Descriptions of the inventions of intending competitors must reach the secretary of the Society of Arts not later than December 31, 1896.

STANDARDIZING LAMP BASES AND SOCKETS.

Mr. G. F. Porter, secretary of the National Electric Light Association, has forwarded us a copy of the subjoined letter, which has been sent out calling a meeting of lamp and socket manufacturers:

New York, Sept. 24, 1896.

Gentlemen:—I beg to advise you that a meeting of manufacturers and central station men to discuss the possibility of standardizing the incandescent lamp base and socket, has been called for Thursday, the eighth of October, commencing at 10:30 a. m. The meeting will be held in the rooms of the American Institute of Electrical Engineers, which are situated on the tenth floor of the Havemeyer Building, 26 Cortlandt street, corner Church, this city.

I may say that every manufacturer previously advised of the intention to hold a meeting has notified us of their desire to be represented. Yours very truly,

FREDERIC NICHOLLS, President.

Electro-Deposition.

THE ANACONDA ELECTROLYTIC COPPER REFINERY.

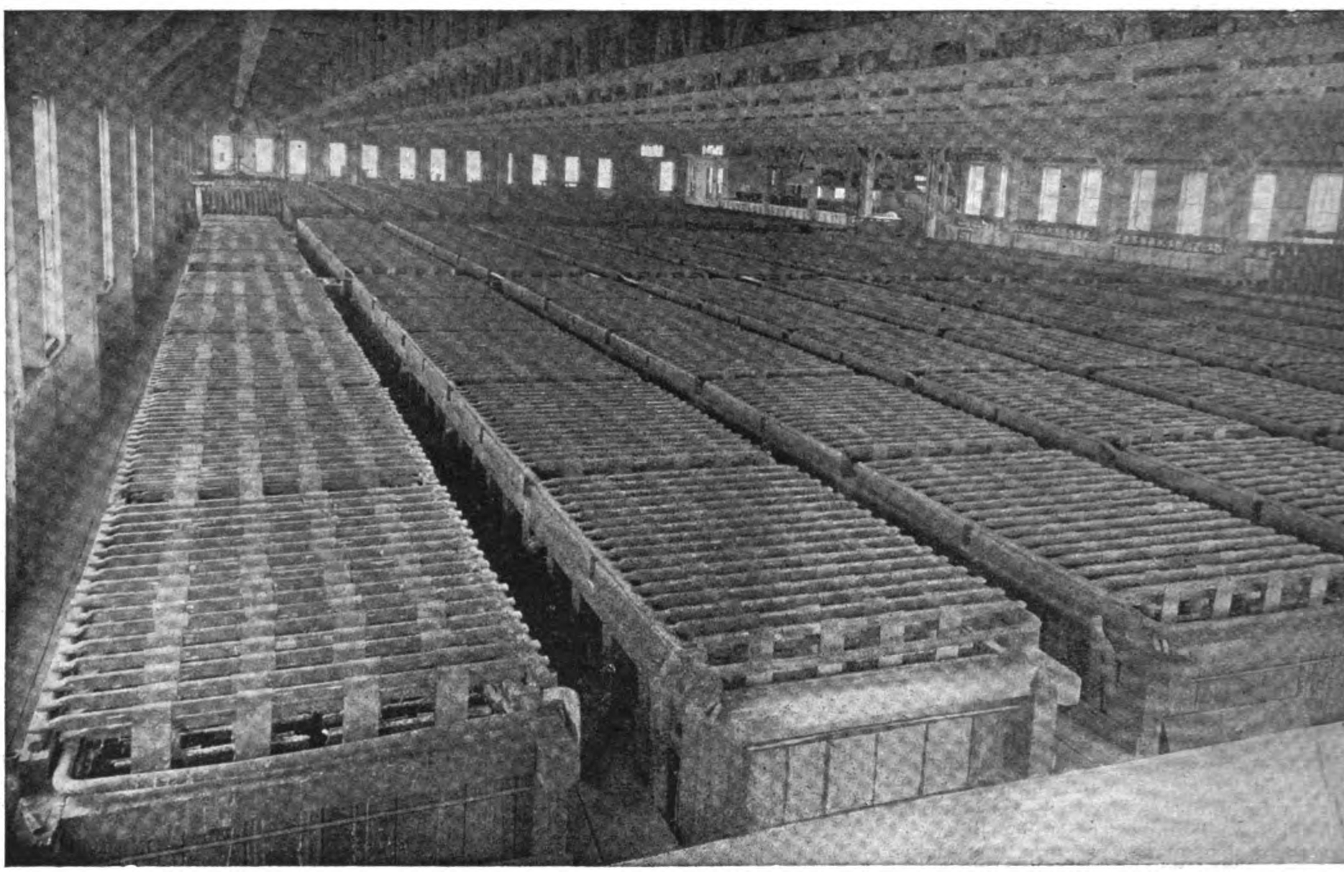
THE considerable quantities of precious metals contained in the copper ores of the Anaconda Mines, Montana, some time ago induced the company owning these famous deposits to install an electrolytic refining plant, the twofold object of which was to secure a pure quality of copper and at the same time to recover the precious metals contained in the ores.

The power house contains Westinghouse engines and dynamos having a capacity of over 2,900 horse-power.

The Refinery Tank House.—The two parts of the refinery are built of wood covered with corrugated iron. Each building covers a space of about 6,500 square yards, and contains 600 electrolytic tanks. Each tank is 2.50 m. long, 1.50 m. wide and 1.00 m. deep. These tanks are built on the self-insulating plan, the air having access to all parts. A wooden framework in the shape of a regular girder is covered on the inside with common planks, and is cut up into compartments by partitions of the same material, 10 of which form a row. Each row of 10 tanks is set on its own foundation, entirely separated from the others and from the working floor. A large air space is between each compartment forming a tank between the working floor and the rows, and all parts of the tanks, at the side as well as below, are of easy access for the air and for the men. Each joint in the woodwork from top of the tanks to the bottom of the foundation is insulated by soaking with insulating material before being put together. The inside of the tanks is lined with lead, and proper protection is provided to preserve it against waste from the copper plates (anodes). On the sides of the tanks the conductors are placed for the electric current, serving at the same time as a support for the electrodes. The bars are of solid copper and are bent in the middle, each reaching over two tanks, being positive on one and negative on the other tank. By means of this bend in the bars all screw connections are avoided between the tanks, leaving only the connections between the different rows to be fixed in the usual way. To support the electrodes flat iron bars are laid across the tanks, resting on the conductors. Copper hooks sustain the plates in the liquid and are hooked on these bars. Ten tanks built together make a row. Ten rows make a set of 100 tanks, and two sets make a system of 200.

As the composition of the crude copper changes in regard to its impurities and as the electrolyte has to be modified according to the amount of such impurities, it is absolutely necessary to be able to separate each system from the others. There are six systems of like capacity of 200 tanks, each being able to turn out about 35 tons of electrolytic copper per 24 hours as a maximum. All the tanks of each system are connected in series for the passage of the electric current produced by one generator. Each row of 10 tanks has its individual supply tank for the circulation of the liquid. The circulation is established by having rows built on an inclined plane. The liquid runs by gravity from one tank to the next until it reaches the last one, from which it falls to the collector. The collector conveys the liquid to the acid pumps, working by air pressure, which deliver it anew to the distributor and from there to the small supply tanks to begin the same course over again.

The three first systems are provided with overhead trolleys, one above each double row, and by means of these the tanks are loaded with copper and also unloaded after it is refined.



Electrolytic Tank Room, Anaconda Copper Refinery.

The full charge of a tank, weighing about four tons of copper, is loaded up and unloaded in one operation.

On the working floor of all the halls runs an electric road of 20-inch gauge, by means of which all material is conveyed from the railroad in the buildings to the tanks, the scales, etc., and back. The locomotives are of Mr. Thofehrn's design, and were built by the General Electric Company. Underneath the tanks runs another 20-inch road, which communicates with the silver mill, and is used to convey nothing but the refinery slimes, which contain, besides the impurities of the crude copper, the gold and silver in large amount.

Operation of the Refinery.—The work which is going on in the refinery, so far as the mechanical part is concerned, is extremely simple. The men take the anodes from the railroad cars, transport them by the tank-load over the scales and place them on a rack. Here the supporting bars and hooks are laid over the anodes, the crane is brought along, picks up the charge, conveys it to the tank it belongs to and lets it down therein, placing at the same time all the plates in the proper position. In the mean time another crew has prepared on a second rack one load of cathodes, hooked on the support-

ing bars and ready for use. These the crane takes up and brings them like the anodes right on the place where they belong. After this the liquid is turned on and as soon as the tank is filled the electric current is started again and the refining work begins.

The crude material upon which the refinery works is blister copper, containing 98 per cent. copper on the average, and the balance in arsenic, antimony, iron, lead, tellurium, selenium, besides about 110 ounces of silver and 1/3 ounce of gold to the ton.

The large number of tanks and the high cost price of labor at Anaconda necessitated a special means of control in this direction. This has been obtained by an automatic device, looking very much like a regular double commutator of a dynamo, to which all tanks are connected by series of five tanks each. A yoke carrying two brushes slides over the different sections of these commutators, making one complete turn in an hour, and these brushes bring into contact the terminals of each series of five tanks to register the voltmeters. In this way all the tanks are controlled once an hour and the readings registered on paper automatically. This enables the man in charge to see at a glance the condition of all the tanks in the refinery.

Copper.—The Anaconda Copper Mining Company's refinery has been running in full since January 1 of this year, and is turning out between 100 and 120 tons of copper daily according to the output of the mines. The balance of the company's product, from 80 to 100 tons, is refined in Baltimore. The total daily production of the Anaconda Company is about 200 tons of copper. The refinery is built in such a way that in case of an emergency it can easily handle the total product of 200 tons daily with the use of additional dynamos only.

In referring to the cost price of refined copper in Anaconda we have to consider the high price of labor, which amounts to nearly $3 on an average per day per man. The cost of fuel so far has been $5.50 per ton, but this expense will be reduced to $2 per ton when Belt coal is used by means of underfed stokers.

Sulphuric acid costs 2.4 cents per pound in Anaconda, while the other supplies cost accordingly. We can say generally that all expenses in Anaconda are more than twice those at Eastern industrial centers. The refining work at Anaconda costs no less than $14 per ton of copper produced, including the saving of gold and silver contained in the anodes.

The average quality of copper produced in these plants is: Conductivity, 98 per cent., Matthiessen standard; tensile strength, 64,000 to 65,000 pounds per square inch; number of twists in 6 inches of No. 12 wire, 80; elongation, 1¼ per cent. All these measurements were taken on hard drawn wire.

Epuration of the Electrolyte.—The anodes are delivered to the refinery containing about 2 per cent. impurities, which, during the process of refining, go partly into the liquid and partly into the slimes. The impurities which go into the electrolyte are partially taken out on each turn of the electrolyte through the tanks. A certain amount of impurities is allowed to stay in the liquid, however, while the epuration process is regulated so as to limit the accumulation of these impurities only. The epuration process used at Anaconda is extremely simple, requires little attention and necessitates the use of air and cheap chemicals only. This method is preferable to the voluminous and bulky old process of crystallizing which is used almost in all Eastern refineries for the epuration of the electrolyte.

Silver and Gold.—The Anaconda Copper Mining Company's refinery produces about 350,000 ounces of silver and about 1,500 ounces of gold per month. This product is delivered to the market in fine bullion. The silver is .999 fine, and the gold .950 fine. The bullion is reduced at a very low expense, the cost being almost nominal. The process for the refining of slimes is as follows: The silver mud (this name is given the slimes) is sent from the refinery in lead-lined tank-cars to the silver mill. Arriving there, it is hoisted up to the screens, where it is washed with water and all chips of copper, etc., are taken out. The clean silver mud is then run out into boiling tanks, where it is freed from its copper contents by boiling with acid and steam. From this first set of boiling tanks the silver mud is passed over a filter on which it is thoroughly washed with water. It is then put into the second set of boiling tanks from which the other impurities, notably arsenic and antimony, are taken out. From here the silver mud is again placed on filters, thoroughly washed with water and dried on large cast iron pans. A consequent melting in the reverberatory furnace reduces the silver mud to ingots ready for the parting kettles. The ingots are then placed in the parting kettles, where they are boiled with sulphuric acid and the silver dissolved, making sulphate of silver, which later on is diluted with water and precipitated by copper plates, thus obtaining pure cement silver. This is thoroughly washed and dried and then melted again into ingots by furnace charges of two tons each. The ingots are now ready for the market and weigh about 1,200 ounces a-piece. They are assayed, stamped, numbered, weighed and shipped as fine bullion of .999 fine.

Thofehrn's New Refining Process.—The density of current generally employed in Thofehrn's refineries for the production of cathodes is about 10 to 20 amperes to the square foot. The product is melted in order to produce ingots or wirebars, according to the demand of the customers. Mr. Thofehrn has devised a process which joins the utmost simplicity with rapid work and good quality of product, being at the same time economical. The process operates as follows: A hollow cylinder about 8 feet long and 3 feet in diameter is immersed in the electrolyte and forms the cathode on which is taken the precipitate of copper with a density of 50 amperes up to 100 amperes per square foot. The anodes in Mr. Thofehrn's tanks are common converter pigs; ingots, shot or scrap, or whatever is at the disposal of the refiner, and white metal containing 75 per cent. to 80 per cent. copper, have all been used satisfactorily. It is an advantage that this copper in its crude market shape can be used without transforming it previously by melting into plates for anodes, and it is a saving of about $3 per ton. The cylinder which is used as a cathode revolves in a tank at slow speed, and the copper that precipitates upon it is in the shape of extremely fine crystals, assuming the form of octagonal needles or hairs, which can only be seen through a powerful microscope. In order to produce a good and dense deposit of copper these microscopic needles or hairs must be interwoven, felted and compressed. This is attained by the action of numerous small jets of electrolyte directed under pressure against the revolving cylinder. While, apparently, to the naked eye no action whatever seems to follow from the jets, the final result is remarkable. The copper deposited is to the full extent of its thickness, thoroughly dense, even after continuous annealing and hammering no foliation whatever can be obtained. The method of directing a stream of fresh electrolyte on the surface of the cathode has another advantage. The whole cylinder is surrounded by the fresh liquid coming from the epuration tanks and no matter how impure the anodes are and how large the amount of impurities in the liquid the cathodes are fully surrounded by clean electrolyte only. After 1-inch thickness of copper is deposited upon the cathode, the precipitate is taken off by opening the cylinder by means of a small hydraulic jack, especially devised for this purpose. The plates of the deposit on the cylinder are not continuous. A small seam is left in the cylinder for the attachment of the hydraulic jack. After opening the plates sufficiently to slide out the cylinder, the latter is placed on a cast iron bed-plate held on one side. A heavy roller is inserted and pulled forward by a hydraulic ram, thus transforming the plate into a flat sheet, having dimensions according to the size of the cylinder used. The plates so produced are ready to go to the rolling mill without previous melting or annealing. In case wirebars are to be produced a full cylinder of copper is deposited on the cathode. This cylinder, after obtaining sufficient thickness, generally 1 inch, is taken off the mandril, placed on a lathe and cut by means of a circular saw into a strip having a width conforming to the demand. As the cylinders are about 8 feet in length and about 3 feet in diameter, the length and weight of these strips are considerable. Generally, the strips produced are 1 inch square in section, and after passing through a roughing die, which cuts away the sharp angles, the strips are directly brought to the regular draw-benches, and can then be drawn down to any desired size without annealing. The quality of the copper produced in this way is higher than that produced in the usual way by melting, etc. The conductivity is generally 100 per cent., Matthiessen standard. The tensile strength is about 75,000 pounds; elongation about 2 per cent.; number of twists in 6 inches of No. 12 wire, about 100. All tests were made on hard-drawn wire. The expense of refining copper by this process is estimated to be about $16 per ton, including all the processes of transforming the crude copper into the finished product, ready for the rolling mill and for the wire-drawing mill.—"The Engineering and Mining Journal."

PERSONAL.

F. G. REW, the Cornell University student who disappeared from Ithaca nearly two years ago and was found last month in Ceylon, where he had gone as an electrician on a French trading steamer, has returned to his home, in Buffalo. He claims that he has no knowledge how he got to this city from Ithaca, and that he "came to himself" on a cattle ship on which he had shipped. His journeyings have completely restored his health, and he will return to college. His disappearance caused a tremendous sensation and murder was long suspected.

NEWS AND NOTES.

A MAGNETIC PLANT.

An account of an interesting plant which has the apparent property of turning its leaves in a north and south direction, thus behaving like the needle of a compass, is given in "Garden and Forest." Mr. E. J. Hill, of Chicago, who seems to have been investigating it, gives the name of the plant as Silphium lacinatum, and says that the Silphium terebintnlnaceum is affected in the same way, 75 per cent. of the latter orienting themselves in the manner mentioned above. The tendency to orientation seems to be a function of the ages of the leaves in question, the younger ones being said to point more accurately north and south than those of greater age, the latter falling off and therefore supplying an insufficient amount of evidence. It is mentioned that Sir Joseph Hooker remarked the uses which might be made of the peculiarity of this plant; it is stated, also, that he was able when traveling to note perfectly the change in direction of the train by observing the general appearance of these plants which were scattered over the plain.

"ELECTRICITY IS LIFE."

Mr. Robert Hilliard has brought out a new farce called "The Mummy," and based on the idea that the mummy of Rameses II. is brought to life by a bright Chicago girl who playfully attaches a galvanic battery to his remains. It is well known that electricity has a vitalizing effect when thus used.

COPPER PRODUCTION AND WAGES.

As offsetting the delusion that gold has advanced in value and that wages are, therefore, lower, and would be raised by calling one silver dollar two, the "Iron Age" prints the records from the Quincy Mining Company, in the Lake Superior copper region. In the period of thirty years the price of copper has been cut in halves, but the wages of the men have risen 25 per cent., although the purchasing capacity of the money is far more than it was. Owing to the introduction of power drills, explosives, etc., the efficiency of the labor has been tripled. The "Iron Age" says that corresponding figures apply all along the line of hoisting, crushing, washing and refining the copper.

TORPEDOES FOR BODY SNATCHERS.

If one may judge from the patent records, live people do a good deal of thinking about death. The very latest device that has been applied to burial appliances is the "coffin torpedo," which is designed as an effective and very summary punishment for body snatchers. Nothing less than a bomb is introduced into the coffin, before the latter is closed, the arrangement being such—we spare the reader all technical details—that any attempt to force it open will release a spring, strike a percussion cap, and set off the bomb. The thing is done, and the robber is floating in pieces about the air long before he has had any time to prepare for his sudden journey.

But what happens to the corpse? The inventor leaves us in the dark on this point—probably because the question is hard to answer. We are afraid the coffin torpedo has no very brilliant future on this account, and for the further reason that local authorities (who are notoriously difficult to deal with) might object to have their burial grounds studded with infernal machines.

A device much more reasonable is the "grave annunciator," for use in the case of burial alive. Any disturbance in the coffin closes an electric circuit, and springs an alarm in the house of the superintendent, who takes note of the number of the grave, and proceeds without further delay to dig up the victim. For the benefit of those whose relatives have been cremated, another inventor has patented a process for converting the ashes of the defunct by the aid of silicate of soda, into paste, which is to be moulded into a bust or statuette.—"Tid-Bits."

WHAT CAMMACK THINKS.

It appears that Mr. Cammack has made a careful investigation of the financial prospects of the General Electric Company and has satisfied himself that the stock will soon be placed on a dividend-paying basis after the capital has been reduced to $15,000,000.—"Boston Advertiser."

THE CREWE HOSPITAL, in England, finds that by using the electric light, the number of beds in the wards can be increased from twenty-eight to forty-five, as the incandescents do not vitiate the air like gas jets, and hence each patient requires fewer cubic feet of space.

ELECTRIC POWER FOR CALAVERAS COUNTY, CAL.

The California Exploration Company has agreed to take 1,500 horse-power of the electric energy to be developed in the Blue Lakes enterprise, employing it in the development of its mining ventures in Calaveras County. The Blue Lakes people are busy at the present time perfecting plans, specifications and details for the work, and considering the matter of contracts for electrical and other supplies. They have more than $100,000 to put into the plant, and have determined to put in the most efficient that money can secure, and of sufficient capacity to generate 6,500 horse-power at the point of delivery. They estimate that that amount will be all that is necessary for some time, and, in fact, may not put in quite that capacity to begin with, but will construct their buildings, foundations, pipe lines and ditches for machinery to develop that amount of power. The electric generating plant will be located at the Keirsing mill site, a little above Big Bar, in Calaveras County, and the water to operate it will be taken from the Blue Lakes ditch, near Madden's tunnel, and carried part way through the old Butte ditch, which will have to be enlarged and repaired, and part of the way through pipe. This summary gives a maximum amount of power with a minimum amount of water. The company has only about eight months to complete its contract.

PUMPING OIL BY ELECTRICITY.

An experiment in pumping oil wells by electricity was made recently on the property of Mr. J. Menisinger, at Lima, O. The current was taken from the street railway circuit at 500 volts and a Triumph 5 horse-power motor was used. The outfit worked well and gave much ground for encouragement, but the uneven supply of current made the operation of the plant unreliable. What is needed is a special plant, or a regular power service.

NOTES.

ELECTRIC TROLLEY BOATS are proposed for the River Spree, near Berlin, for the purpose of towing barges.

SAVING THE FORESTS.—It is pointed out that the use of electric power in the mining regions and timber belts of the far West, where coal had been costly and difficult to obtain, is doing much to conserve the forests, whose denudation was becoming a serious evil.

STUDYING TERRESTRIAL MAGNETISM.—An observatory for terrestrial magnetism has been established in connection with the astronomical observatory in Munich, and Dr. Franz von Schwarz has been made director.

OBITUARY.

MRS. H. C. C. OVERBURY.

The sad news comes from Niagara Falls of the death in that city of Mrs. Helen Cary Condit Overbury, wife of Mr. Frederick Overbury, manager of the new plant of the Chemical Construction Company, recently described in these columns. Mrs. Overbury's death occurred shortly after noon on Wednesday, September 23, at the family home on Eleventh street. She was but twenty-two years old, and her death following so soon after they had taken up their residence at Niagara is especially sad. While living at the Falls Mrs. Overbury made many friends, who sorrow at her early death. The remains were taken to Boonton, N. J., for interment.

DAVID C. SPRAGUE.

We regret to record the death of David C. Sprague, the father of Frank J. Sprague. He was killed in Rahway, N. J., where he lived, about nine o'clock on Thursday morning, Sept. 24, by a fast freight train on the Pennsylvania Railroad, near the Poplar street crossing. He attempted to cross the track, evidently not hearing the rapidly approaching train, and was hurled against the flaghouse.

David Cummings Sprague was born in New England about sixty-three years ago and was a member of one of the oldest families of that part of the country. He lived for years at Milford, Conn., until his wife died, thirty years ago. Afterwards he went to Colorado and spent twenty years in mining regions of that and other Western States. Later he represented the Sprague Electric Railway and Motor Company in Buenos Ayres. At the time of his death he was the manager of the Eustis Manufacturing Company, at Rahway. He leaves two sons, Frank J., president of the Sprague Electric Elevator Company, and Charles M. Sprague, treasurer of that company.

MRS. F. R. COLVIN.

We regret to note the death, Sept. 28, in this city, of Mrs. F. R. Colvin.

Synopsis of Current Electrical Literature.

EDITED BY MAX OSTERBERG, E. E.

Alternating Currents:

LEAD OR LAG?—By W. G. Rhodes, M. Sc. Capacity causing a displacement of phase between the e. m. f. and current, the question arises does it cause a lead or lag. Author finds by mathematical reasoning that, if we call the displacement of phase of current over e. m. f. due to self-induction, a lag, we are driven to calling that due to capacity a lead.—Lond. "Elec. Rev.," Sept. 4, '96.

Central Stations:

CLEVELAND ELECTRIC ILLUMINATING COMPANY.—Illustrated description of the station which consists in the main of four vertical boilers, three of which are rated at 800 h. p. each, and one at 500 h. p. They work under 200 pounds of pressure. Three engines are installed, capable of developing 750 h. p. each, and these are connected by shafting to the various generators.—"Elec. World," Sept. 5, '96.

Dynamos and Motors:

ON THE SEAT OF ELECTRO DYNAMIC FORCE IN IRONCLAD ARMATURES.—By Townsend Wolcott. A discussion of the paper on the same subject by Houston and Kennelly, printed July 4, '96.—"Elec. World," Sept. 5, '96.

LOAD LOSSES PRODUCED BY ARMATURE CURRENTS.—By Harris J. Ryan. Referring to Mr. Blathy's load losses, Prof. Ryan mentions that in making the tests on the World's Fair dynamos, he, in conjunction with Dr. C. E. Emery, observed similar effects; he is also of the opinion that most dynamo manufacturers are aware of the armature lag.—"Elec: World," Sept. 5, '96.

COMBINED ALTERNATING AND CONTINUOUS CURRENT DYNAMOS.—A combined system in one machine has had a trial at Woolwich, where the distribution is accomplished by alternating current at ordinary pressures and the transmission at 2,000 volts alternating current. The alternator feeds into the transmission mains, while the dynamo feeds into the storage battery. By running the dynamo as a motor from the batteries and assisting the engines, the alternator's output can be nearly doubled.—Lond. "Elec. Rev.," Sept. 4, '96.

ABSOLUTE STANDARDS OF SELF INDUCTION.—By Max Wien. Description of coil, which author guarantees to be made close enough to warrant its correctness within one per cent.—"Wiedemann's Ann.," p. 553, vol. 58, Abstracted in ""Elektrotechn. Zeitschr.," Aug. 20, '96.

Electro-Chemistry:

DRAWING AND ROLLING ALUMINUM.—F. L. Rawson of the Industrial Inventions Development Company, England, announces that a new process for drawing and rolling aluminum is being introduced. Aluminum can, up to the present time, only be cast. (?) This notice appeared in "Industries and Iron," Aug. 28, '96.

NOTES ON THE ELECTROLYTIC DETERMINATION OF IRON, NICKEL AND ZINC.—By H. H. Nicholson and S. Avery. Several tables giving the current, time, weight, etc., of the solutions. From "Ztschr. anorg. Chem." in Lond., "Industries and Iron," Aug. 28, '96.

PROCESS FOR ELECTROLYTIC DESILVERING ARGENTIFEROUS LEAD.—By D. Tommasi. The principle on which this procedure is founded consists in electrolyzing a lead solution, which not merely possesses an extremely weak electric resistance, but does not give rise to lead peroxide (PbO_2), and, in taking the argentiferous alloy itself as anode and cathode, a metallic disc which cannot be attacked by the bath.—"Eng'ing and Min. Journ.," Aug. 29, '96.

THE DUMOULIN COPPER DEPOSITING PROCESS.—A process of some possible potential importance is being experimented with in England for the purpose of depositing copper electrolytically, in the form of sheets and tubes, direct from the matte or precipitate. The essence of the invention is the special method for rendering the arrangement of the deposited molecules perfectly homogeneous, and thus obtaining uniform strength in the tube as it is formed on the revolving mandrel.—"Eng'ing and Min. Journ.," Aug. 29, '96.

A CONTRIBUTION TO THE HISTORY OF THE ELECTROLYSIS OF ALKALINE CHLORIDES.—By Geo. Lurege, Ph. D. An attack on Mr. Andreoli's work "Electrolysis of Chlorides," in which the author shows that Andreoli has not sufficiently credited the German and French patentees with priority patents. "Eng'ing and Min. Journ.," Sept. 5, '96.

DILUTION LAW OF ELECTROLYTES.—By L. Storch. Author has discovered a new law of conductivity for infinite solutions. (An infinite dilution is that at which the electrolyte has the greatest conductivity.)—"Zeitschr. f. Physik. Chemie.," Vol. XIX., p. 13, '96. Abstr. in Lond. "Elec. Rev.," Sept. 4, '96.

APPLICATION OF ELECTROLYSIS IN THE MANUFACTURE OF BEET SUGAR.—By G. Ehrlich. A description of the Schollmeyer methods of purifying the sugar with several numerical examples taken from reports of actual experiments.—"Elektrochem. Zeitschr.," Sept., '96.

Electro-Physics:

STATIC CHARGE OF ELECTRICITY UPON THE SURFACE TENSION OF WATER.—By E. L. Nichols and J. S. Clark. Experiments are described upon the size of the drop delivered by a water dropper at different electric potentials. The object of the paper is to obtain direct evidence of the electric charge upon the surface tension.—Abstracted in "Electrical World," Sept. 5, '96.

Isolated Plants:

ELECTRICITY IN SHIPS.—By F. Eickenrodt. Paper read before the Institution of Naval Architects, June 13, '96. Author treats the subject from the shipbuilder's point of view and finds many inherent advantages in the use of electric motors for all possible purposes, principally on account of cleanliness, space saved, and simplicity of management.—"Elektrotechn. Anzeiger," Aug. 23, '96.

CONNECTING INCANDESCENCE LAMPS IN SERIES ON ALTERNATING CURRENTS.—A study of the connections in series on reaction coils and on little individual transformers.—Lond. "Elec. Rev.," Sept. 4, '96.

Lighting:

ELECTRIC LIGHTING IN BELFAST.—Some illustrations to accompany the paper, by V. A. H. McCowen, previously referred to, showing curves of gas consumption, plotted from the results of tests on a tandem and on a single gas engine. They show the total consumption per hour, per indicated horse-power hour, per electrical horse-power hour, and also the percentage of efficiency, or ratio of electricity to indicated horse-power.—Lond. "Elec. Eng'r," Aug. 28, '96.

CONSUMPTION OF ELECTRIC ENERGY IN INCANDESCENCE LAMPS IN REFERENCE TO THE NEW TARIFF.—By Francesco Personali. Exhaustive experiments made in a large factory determining the exact amount of energy consumed by the lamps in comparison with their candle power.—"Lond. Elec. Rev.," Aug. 28, '96.

Magnetism:

MAGNETIZATION AND HYSTERESIS OF SEVERAL QUALITIES OF IRON AND STEEL.—By H. du Bois and E. Taylor Jones. A thorough investigation of eight distinct qualities, materials of different hardness. No chemical analyses are given, but all materials are such as can be procured in the market.—"Elektrotechn. Zeitschr.," Aug. 27, '96.

MAGNETIC RESEARCHES OF THE PHYSIKALISCH TECHN. REICHSANSTALT.—By Dr. A. Ebeling. Review of the methods employed to do the most accurate work.—"Elektrotechn. Zeitschr.," Aug. 20, '96.

SECULAR VARIATION OF TERRESTRIAL MAGNETISM.—By L. A. Bauer. Paper read before the Am. Assoc. for the Advancem. of Science. That part of the earth's permanent magnetism which is symmetrical about the earth's rotation axis is separated from that which is unsymmetrical.—Abstract in "Elec. World," Sept. 5, '96.

MAGN. & HYST. of CERT. KINDS OF IRON & STEEL.—By Du Bois & James. Add.—Lond. "Elec. Rev.," Sept. 4, '96.

Mechanical:

THE OLIN GAS ENGINE.—This engine is designed to work principally in the oil regions and is claimed to run on 10-15 cubic feet of gas or gasoline vapor per h. p. hr.—"Am. Manuf.," Sept. 4, '96.

WESTINGHOUSE GAS ENGINE.—An illustrated description.—See "Iron Trade Rev.," Sept. 3, '96.

Miscellaneous:

A NEW POLE LIGHTNING ARRESTER.—By J. Berliner. This consists of a porcelain double petticoat on which a metallic ring is fastened. The discharge takes place through a great many small metallic teeth.—"Elektrotechn. Anz.," Aug. 27, '96.

METHODS OF CHARGING FOR ELECTRIC ENERGY.—By L. Andrews. Two different systems of charging for electric energy exist in Brighton and Hastings. Author presents curves showing the ratio of the quarterly expenditure to the quarterly receipts under the two systems.—Lond., "Lightning," Sept. 3, '96.

POSTMASTER GENERAL'S REPORT.—An abstract of an English report showing the results for the year ending March 31, '96. A total of 78,839,610 telegrams, an increase of 10.12 per cent. over the previous year, were sent.— "Lond. Elec. Eng'r.," Aug. 28, '96.

SOCIETE INTERNATIONALE DES ELECTRICIENS "SCHOOL OF APPLICATION."—A prospectus of the school. —"Lond. Elec. Rev.," Aug. 28, '96.

Railways:

HARTLEPOOL ELECTRIC TRAMWAYS.—Length of line, 2½ miles. Boilers working at 140 pounds pressure evaporate 3,400 pounds of water per hour. Two Willans engines of 100 indicated horse-power with 450 revolutions supply the power for two direct coupled 500 volts and 120 amperes dynamos Details of plant with illustrations in Lond. "Lightning," Aug. 27, '96.

Roentgen Rays:

PRESCRIPTION FOR A FLUOROSCOPE.—To two parts of tungstate of sodium is added one part of calcium chloride, and the mixture is fused to a red heat. A resulting compound of calcium tungstate and sodium chloride is formed, which latter salt exerts active hygroscopic properties, and, as a result renders the calcium tungstate quite negative to the X-rays. The fused mass, however, is immersed in water for forty-eight hours, when the salt is dissolved out, leaving the insoluble calcium tungstate as a precipitate. This is separated by filtration, and, when dry, assumes a crystallized form and is very sensitive to the X-rays. This is spread evenly over the screen, a matter at first of some difficulty, but one easily overcome with a little practice. Copied from The Electrical Engineer in Lond. "Industries and Iron," Aug. 28, '96.

REGULATION OF VACUUM IN CROOKES' TUBES.—By Ralph McNeill. In a letter the author remarks that by reversing the current in a tube for some time the vacuum may be sufficiently weakened to produce the proper X-ray effect, thus making the re-exhausting unnecessary.—"Scient. Amer.,"

SOME EXPERIMENTS WITH CHEMICALS.—By Sehrwald. Author finds that halogens are quite opaque to the rays. "Deutsche med. Wochenschr." and in abstract in "Elektrochem. Zeitschr.," Sept., '96.

X-RAY SCREENS.—By Charles Henry. Author uses a screen of phosphorescent sulphide of zinc, covered with a sheet of stiff paper and lays the object to be photographed upon the paper. The impression of light and darkness remains on the screen for fifteen minutes and even longer if slightly heated.—"Comptes Rendus." Aug. 24, '96, Abstract in Lond. "Elec." Sept. 4, '96.

PART PLAYED BY THE DIELECTRIC IN THE DISCHARGE BY ROENTGEN RAYS.—By Jean Perrin. A series of interesting discharge experiments.—"Comptes Rendus," Vol. 123, No. 6, p. 351. Lond. "Elec.," Sept. 4, '96.

ON THE ELECTRIC CONVECTION ALONG THE LINES OF FORCE CAUSED BY ROENTGEN RAYS.—By Prof. Righi. Experiments tending to show that the action of X-rays results in convection movements along the lines of force of an electric field.—"Comptes Rendus," Aug. 24, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED SEPT. 22, 1896.

Alarms and Signals:—

ELECTRIC SIGNALING DEVICE. G. F. Knollmann, Evansville, Ind., 567,984. Filed Aug. 7, 1896.
Means of signaling between locomotives traveling on the same tracks.

SIGNAL FOR CABLE RAILROADS. M. Norden, New York, 568,205. Filed June 29, 1896.
An electrically actuated device for detecting broken strands in the cable.

Batteries:—

PROCESS OF TRANSFORMING CHEMICAL ENERGY OF FUEL INTO ELECTRICAL ENERGY. W. Borchers, Duisburg, Germany, 567,959. Filed Nov. 21, 1894.
Consists in placing a bath of cuprous chlorid in a closed circuit and dissolving fuel gas in it at one point and oxygen of the air at another point.

ELECTRIC BATTERY. H. C. Thomson, Boston, Mass., 568,007. Filed June 25, 1896.
Contains a carbon element and a zinc element which are held separated without the use of rubber rings.

ELECTRODE. H. Blackman, New York, 568,229. Filed Feb. 9, 1895.
Consists of a dense impermeable mass of combined electroconductive iron oxid and a flux capable of acting to promote the fusion of the oxid.

ELECTRODE FOR ELECTROLYTIC DECOMPOSITION. H. Blackman, New York, 568,230. Filed May 9, 1895.
Similar to above.

ELECTROLYTIC ANODE AND APPARATUS. H. Blackman, New York, 568, 231. Filed May 31, 1895.
Similar to above.

Conductors, Conduits and Insulators;—

INSULATOR. W. Wood, Middlebury, Conn., 568,060. Filed March 11, 1896.
Consists of two tubular parts placed one within the other, both provided with an oblong slot which communicates with the central bore.

METHOD OF MAKING UNDERGROUND CONDUCTORS. J. H. Croskey and J. Locke, Pittsburg, Pa., 568,298. Filed May 21, 1896.
A section of conduit comprising a cover and a lining of glass molded into the casting and around a core sustained therein.

Electro-Metallurgy:—

ELECTROLYTIC APPARATUS FOR EXTRACTING GOLD AND SILVER FROM THEIR ORES. L. Pelatan, Paris, France, and F. Clerici, Milan, Italy, 568,099. Filed Oct. 1, 1895.
Comprises a vat, a mercury cathode upon the flat bottom thereof, an endless belt anode, a portion of which is in parallelism with the bottom of the tank and means for moving the anode continuously in one direction.

Lamps and Appurtenances:—

APPARATUS FOR MANUFACTURING INCANDESCENT ELECTRIC LAMPS. G. R. Lean and J. R. Massey, Cleveland, O., 568,142. Filed Dec. 21, 1895.
A machine comprising a bulb-holder, means for forming a hole in the enlarged end of the bulb, and devices for welding a tube to the bulb so as to communicate with the hole.

MATERIALS AND PROCESS FOR INCANDESCING MANTLES. William L. Voelker, Elizabeth, N. J., 568,184. Filed May 19, 1896.
Consists in mixing together the oxids of magnesium and calcium and then electrically heating them to a very high temperature.

ELECTRIC LAMP FOR VELOCIPEDES, ETC. A. M. Rodriguez, Brooklyn, N. Y., 568,209. Filed Dec. 20, 1894.
A small dynamo is driven from a wheel of the velocipede and feeds an incandescent lamp.

COMBINED GLOBE-HOLDER AND ASH-PAN. T. E. Adams, Cleveland, O., 568,223. Filed April 6, 1895.
The combination in an electric arc lamp with the carbons and a globe-holder, of a rod secured to the globe-holder independently of the holders of the carbons, the rod being so disposed as to receive heat from the arc and conduct it to the globe-holder.

INCANDESCENT LAMP. J. T. Lister, Cleveland, O., 568,262. Filed April 25, 1896.
Employs two pairs of filaments inserted at opposite ends of the bulb.

Miscellaneous:—

ELECTRIC HAND LIGHTING GAS BURNER. G. J. Galbraith, Boston, Mass., 567,971. Filed June 25, 1896.
The movement of the thumb piece serves to oscillate the three-gas valve and also to vibrate an electrode at the top of an elongated gas pillar.

ELECTRICALLY HEATED SMOOTHING SURFACE. W. S. Hadaway, Jr., 567,976. Filed March 24, 1896.
A coil of wire placed within the smoothing cylinder and clamped therein.

MULTIPLE CIRCUIT CLOSER FOR ELECTRIC TRAP PULLING Devices. T. R. Barney, San Francisco, Cal., 568,013. Filed April 21, 1896.
Details of construction.

THERAPEUTIC ELECTRODE. J. S. Muir, Stockton, Cal., 568,095. Filed April 17, 1896.
Consists of a flexible backing of non-conducting material, a flexible sheet of electro-conducting material, upon the face of the backing and a layer of pliable substance of conducting character upon the face of the conducting sheet.

APPARATUS FOR PRODUCING OZONE. N. Tesla, New York, 568,177. Filed June 17, 1896.
Means for charging a condenser, a circuit of low self-induction into which the condenser discharges, a coil for raising the potential of such discharge, and means for passing a current of air through the high potential discharge.

APPARATUS FOR PRODUCING ELECTRIC CURRENTS OF HIGH FREQUENCY AND POTENTIAL. N. Tesla, New York, 568,176. Filed April 22, 1896.
Comprises a circuit of high self-induction and means for making and breaking the same, a condenser around the point of interruption in the circuit, and a transformer the primary of which is in the condenser circuit.

METHOD OF AND APPARATUS FOR PRODUCING CURRENTS OF HIGH FREQUENCY. N. Tesla, New York, 568,179. Filed July 6, 1896.
Consists in generating an alternating current, charging a condenser thereby during determinate intervals of each wave thereof and discharging the condenser through a circuit of low self-induction.

APPARATUS FOR PRODUCING ELECTRICAL CURRENTS OF HIGH FREQUENCY. N. Tesla, New York, 568,180. Filed July 9, 1896.
Similar to above.

ELECTRIC SIGN. M. Norden, New York, 568,204. Filed Feb. 28, 1896.
Details of construction.

PROCESS OF AND APPARATUS FOR DISTILLING FATTY SUBSTANCES. V. J. Kuess, Bordeaux, France, 568,258. Filed April 6, 1895.
Consists in passing an electric current through the substances and simultaneously injecting into the same a current of steam which is decomposed by the electricity and acts as a conductor for it through the mass.

Railways and Appliances:—

TROLLEY AND TROLLEY SUPPORT FOR ELECTRIC CARS. W. Grunow, Jr., 567,975. Filed Sept. 23, 1895.
Adapted for conduit use.

ELECTRIC BRAKE. A. F. Macdonald, Schenectady, N. Y., 567,-989. Filed April 18, 1896.
Alternates the machines used as current generators in a four-motor equipment.

APPARATUS FOR CONTROLLING ELECTRIC MOTORS. H. W. Leonard, East Orange, N. J., 568,088. Filed April 30, 1896.
Comprises a rheostat, a line switch closed thereby, and means for automatically opening switch independently of the movement of the rheostat contact lever when the energy in the circuit exceeds a certain amount.

ELECTRIC CAR HEATER. J. G. Noyes, Milford, Conn., 568,168. Filed April 8, 1896.
The heating portion is removable.

APPARATUS FOR GENERATING ELECTRICITY FOR LIGHTING OR HEATING RAILROAD CARS. C. E. Dressler, New York, N. Y., 568,193. Filed May 2, 1894.
The dynamo is driven by a blower operated by a motor on the car axle.

Regulation:

AUTOMATIC DEVICE FOR ELECTRIC CURRENT REGULATION. E. W. G. C. Hoffman, Charlottenburg, Germany, 567,982. Filed April 17, 1896.
Comprises a relay provided with auxiliary coils, respectively, to assist and oppose the main relay coil, and a circuit controlling device adapted to connect one or the other of the coils in circuit.

METHOD OF REGULATING APPARATUS FOR PRODUCING CURRENTS OF HIGH FREQUENCY. N. Tesla, New York, 568,-178. Filed June 20, 1896.
Consists in varying the frequency of the impulses of current from the supply circuit.

Telephones:—

TELEGRAPH INSTRUMENT. O. M. Runkle, Columbus, O., 568,-103. Filed June 2, 1896.
A key having its working parts inclosed.

Telephones:

SUBSTANCE FOR TELEPHONE ELECTRODES. D. Drawbaugh, Eberly's Mill, Pa., 567,966. Filed Jan. 10, 1896.
Composed of granular platinum having its surface covered with a reduced silver salt.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE PERKINS HEAT REGULATING SWITCH.

NOW that the fall and winter seasons are upon us, street railway managers who have an eye to the comfort of their patrons are looking sharply after their car-heating appliances. Among the latter, of importance second only to that of the electric heater itself, is the heat-regulating switch—for it is evident that passengers may be as much oppressed by a superabundance of heat as they may be made to suffer from lack of it. A good heat-regulating switch is, therefore, an essential part of the heating outfit and to fully meet the demands of such a device the Perkins Electric Switch Manufacturing Company, of Hartford, Conn., have brought out the switch illustrated in the accompanying engraving.

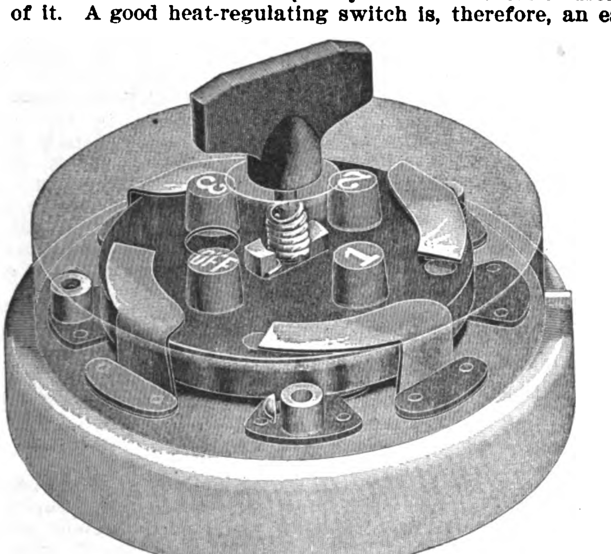


FIG. 1.—THE PERKINS HEAT REGULATING CAR SWITCH.

This switch is a modification of the well known Gibbs switch, manufactured by the same company. The handle, upon being turned from left to right, raises, by means of a screw thread cut thereon, a nut, loose in the insulating block, which is then carried forward, as soon as released from a lock in the base, with great rapidity, and, after a quarter revolution, drops again into a lock, where it is firmly held. The parts revolve in one direction only.

A feature of this switch consists in the loose contact pins, allowing automatic adjustment between the points, so that when "made," contact is assured with every point by the pressure of strong spring copper brushes upon one end of the pin, forcing the other against the adjoining contact plates. When in contact, the insulating block is free to move slightly in any direction, and cannot bind the contact pins.

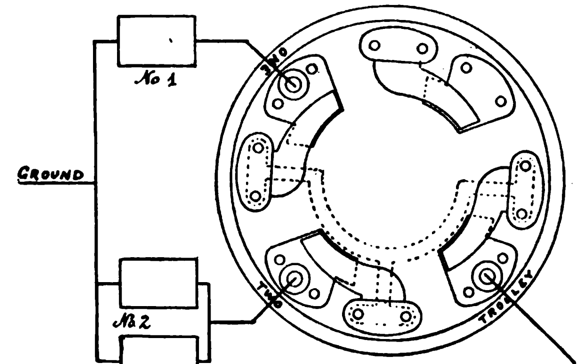

FIG. 2.—THE PERKINS HEAT REGULATING CAR SWITCH.

Another valuable feature of this switch consists in the four simultaneous breaks of the circuit, each time the switch is turned from one position to the next, thus reducing the sparking to a minimum.

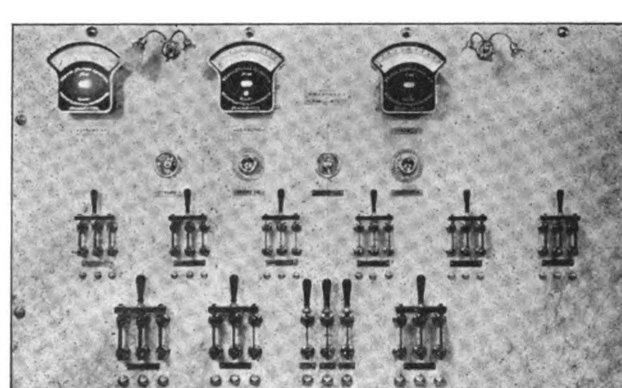
The heat-regulating switch is used for the regulation of heat by different combinations of the heaters. The diagram of connections is shown in Fig. 2. On the commutator are four raised bosses or dials, on which are printed "OFF," "1," "2," "3," respectively. These dials appear successively before a hole in the cover, and thus indicate the position of contacts in the commutator.

From the "off" position, as indicated by dial, the first quarter turn connects in circuit the heaters No. 1, and the figure 1 appears on the dial. The second turn throws out of circuit heaters No. 1 and connects in circuit heaters No. 2, and the figure 2 appears on dial. The third turn connects heaters No. 1 and No. 2 in parallel, which gives the maximum amount of heat and the figure 3 appears on the dial.

The switch is well made in all its parts, and is capable of taking 15 amperes at 500 volts, having a quadruple break.

BALL SWITCHBOARD WORK.

WE illustrate in the accompanying engraving the Italian marble switchboard lately installed at James McCreery & Co.'s dry goods house on West Twenty-third street, New York City, by the H. P. Ball Manufacturing Company, No. 101 Beekman street, New York, for Messrs. H. B. Coho & Co. This switchboard is 10 feet long and stands 7 feet high. Only the switches appear on the face of the board, as the lugs, bus-bars, connections, and fuses are placed behind the board.



MODEL SWITCHBOARD FOR SMALL PLANT.

A novelty in this board which at the same time lends an artistic appearance to the switches, is the type of switch which has been brought out exclusively for switchboard work by the H. P. Ball Manufacturing Company. These switches have

round bases holding the clips, instead of square, as they have heretofore been. This round base is handsomely turned, polished and lacquered and the clips are finished down to this form by hand, which gives the completed article a very handsome appearance.

The switchboard controls 2 50-kilowatt Eddy generators, direct connected to two Ideal engines. The instruments are the Weston illuminated dial pattern. A voltmeter switch is arranged to measure not only the voltage of the individual generators but also the potential between the various circuits and the ground. The H. P. Ball Manufacturing Company have been very much complimented on this installation.

NEW CONTRACTS OF THE ST. LOUIS IRON AND MACHINE WORKS.

The St. Louis Iron and Machine Works have just completed the steam plant for the Maryville, Mo., Electric Light and Power Company, and the new plant is now furnishing lights for the entire city. The equipment consists of a boiler plant of 250 horse-power capacity, a St. Louis Corliss engine of 250 horse-power capacity, a Thomson-Houston arc dynamo of 40 light capacity, a 50 kilowatt, General Electric alternating dynamo, and a 75 kilowatt Fort Wayne alternating dynamo.

The St. Louis Iron and Machine Works are also furnishing the new power plant for the Trenton, Mo., Thomson-Houston Electric Light and Power Company, and will install a St. Louis Corliss engine of 125 horse-power capacity, with line shafting, belting, etc. When the new machinery is installed and in operation, the old plant will be abandoned. New dynamos will be purchased.

The St. Louis Iron and Machine Works are furnishing the entire steam plant for the new lighting station of the Bement. Ill., Electric Light and Power Company. This will consist of two horizontal steel boilers, one St. Louis Corliss engine of 125 horse-power capacity, line shafting and belting.

NECKTIE ELECTRIC LIGHT.

The Ohio Electric Works, Cleveland, Ohio, have just placed on the market an electric light for neckties that is novel and useful. It consists of a candle-power lamp with two small pocket batteries connected, and by pressing a button a light sufficient to read by is given. It is being used on the stage by minstrels and actors, and also by the police and watchmen. It is not a toy, but a useful little electric light apparatus. The price is $3 for the complete outfit, and a liberal discount is allowed to the trade. A complete sample will be forwarded for $1.50, on application.

STEAM MOTOR MACHINE STOKERS.

The American Stoker Company, of Dayton, Ohio, has recently perfected a steam motor which is applied to each stoker, thus making each machine independent. This renders the work of installation very simple. It also renders the stoker practicable for use under marine boilers.

This company is desirous of a general representation through engineering firms handling pumps, heaters and boiler room supplies, and invites correspondence from interested parties.

THE WIRT DYNAMO BRUSH.

We have received an advance copy of an interesting circular describing the new Wirt dynamo brush, manufactured by Mr. Charles Wirt, of 1028 Filbert street, Philadelphia.

In this new brush Mr. Wirt employs his well known sandwich arrangement, but the materials employed have been changed. The conducting part of the brush consists of pure leaf copper, hard rolled, which is placed in the middle. On either side of this is placed a layer of high resistance metal, very thin and with a certain amount of spring temper. Then follows again on either side a layer of antifriction foil, the amount of which is varied with the nature of the service. This adds to the smoothness of running and reduces frictional wear. Outside of all come the stiffening strips of copper providing a low resistance circuit to the brush holder. These latter strips do not reach the commutator and have no part in the current collection.

The new type of Wirt dynamo brush is non-sparking and flexible, and all interested should write for the circular in which Mr. Wirt describes very clearly the rationale of its construction.

READY REFERENCE FOR ENGINEERS AND STEAM USERS.

There are a thousand and one questions constantly arising in the use of steam in engines and boilers, the answer to which cannot be carried around in one's head. Messrs. Houston, Stanwood & Gamble, engine builders, of Cincinnati, have just issued a new edition of their "Ready Reference for Engineers and Steam Users," by Mr. J. B. Stanwood, M. E., in which these questions are answered in a clear and understandable way. The many practicable hints on the design and construction of engines and boilers will be of special use to intending purchasers, embodying as they do the experience of many years.

Messrs. Houston, Stanwood & Gamble have also issued a new catalogue of their slide valve engines and tubular boilers, which is excellently illustrated and contains much useful information. Both the "Ready Reference" and Catalogue can be had free on application.

THE WILLARD STORAGE BATTERY.

We have received from the Willard Electric & Battery Company, of Cleveland, Ohio, their new catalogue, containing a list of the sizes and capacities of all the types of cells made by them for various purposes. These cells are built in sizes varying from the small pocket cell to the heavy central station accumulator. The Willard automatic switch is also described and illustrated. A valuable addition is the "Directions for Charging Storage Batteries," from continuous current, as well as in connection with alternating circuits, which will prove very useful in the hands of battery users.

ADVERTISERS' HINTS.

THE WHEELER REFLECTOR COMPANY illustrate one style of their reflectors. They claim to be the largest manufacturers of these goods in the world, for every conceivable use.

THE E. G. BERNARD COMPANY are advertising their dynamos and motors in which the magnetic field is made of one piece of forged iron. This type of machine has been shown to possess many advantages over other makes and they say their cost is moderate.

THE CUTTER ELECTRICAL & MANUFACTURING COMPANY carry a stock of "I-T-E" circuit breakers and "C S" switches, sufficiently large to meet all ordinary demands without delay.

THE MIDLAND ELECTRIC COMPANY are introducing a dry battery which they state is about as near perfection as it is possible to attain. They sell for fifty cents per cell, with liberal discounts to the trade.

MR. F. M. LOCKE, Victor, N. Y., is doing a good business in insulators, especially in the triple petticoat patterns in china and glass for all line construction.

THE BERLIN IRON BRIDGE COMPANY guarantee their corrugated iron roof covering not to drip in the coldest weather. Being fireproof as well, it commends itself for use in the construction of machine shops, boiler rooms, lighting plants and other buildings where the fire risk is great.

THE CLIMAX GAS ENGINE COMPANY, 31 Fulton street. Brooklyn, invite inspection of one of their engines exhibited with a volt, ampere and gas meter in full view, showing very plainly the amount of gas consumed and the amount of energy generated.

THE WESTON ELECTRICAL INSTRUMENT COMPANY call attention to a line of cheap but excellent instruments for direct current circuits, well adapted for isolated plants.

THE ELECTRIC APPLIANCE COMPANY give a few good reasons why it pays to purchase "O K" weatherproof wire.

NEW YORK NOTES.

IN THE BIG STORE.—The new inclosed arc light has been put to a most complete practical test in the Siegel-Cooper Building of New York, which is equipped throughout with the "Pioneer" lamp. All visitors to the "Big Store" have commented on the softness, steadiness and noiselessness of this new daylight. The "Pioneer" is manufactured by the Electric Arc Light Company, of 687 and 689 Broadway, New York.

WESTERN NOTES.

THE WALKER COMPANY, Cleveland, report that owing to their large and growing business on the Pacific coast, they have found it necessary to establish a branch factory in San Francisco, at the corner of Fremont and Howard streets.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

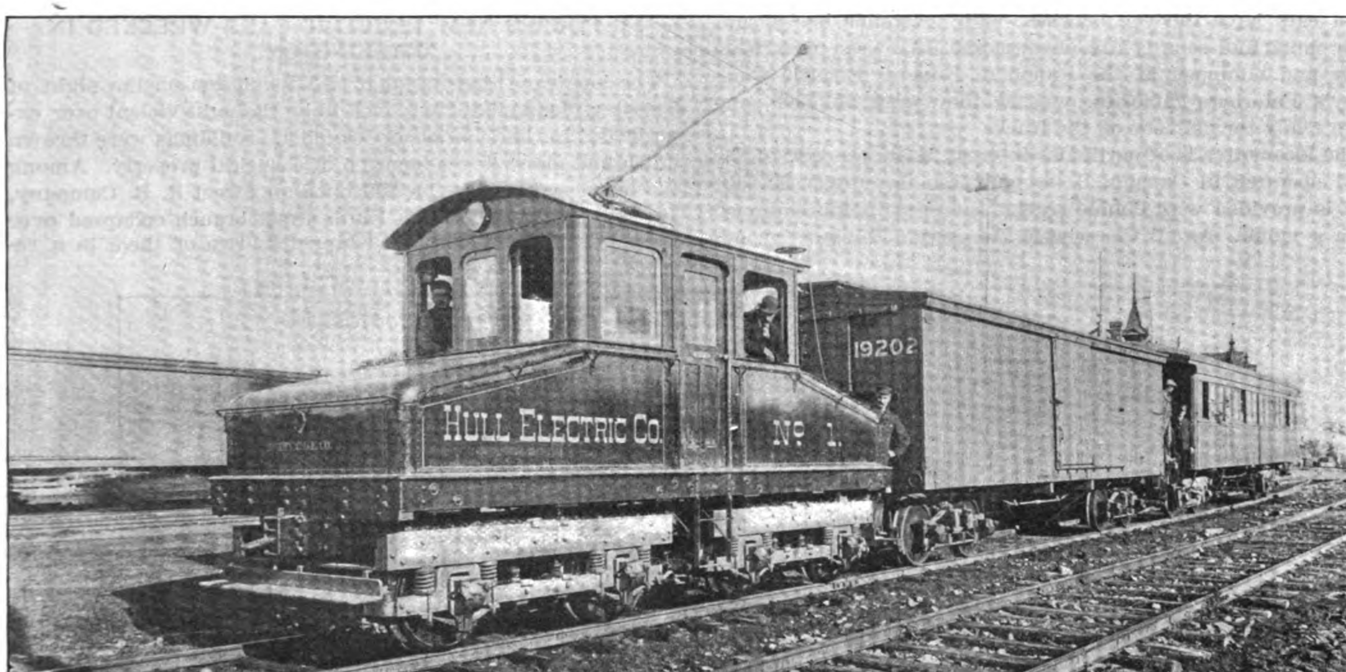
Vol. XXII. OCTOBER 7, 1896. No. 440.

Electric Transportation.

THE AYLMER BRANCH OF THE CANADIAN PACIFIC RAILWAY OPERATED BY ELECTRICITY.

THE latest development in Canadian electric railway work is the equipping of the Aylmer branch of the Canadian Pacific Railway with electric service. This line extends from Hull, a suburb of Ottawa, to Aylmer, where it connects with the Pontiac Pacific Junction Railway, extending 60 or 70 miles up the north side of the Ottawa River. The section from Hull to Aylmer has been leased by the Hull Electric Company for a term of thirty-five years, the understanding being that, besides passenger and mail traffic, they are to handle all through and local freight delivered to them by either the Canadian Pacific Railway or the Pontiac Pacific Junction Railway. As they are the only connecting link with the Pontiac Pacific Junction road, it can readily be understood that the quantity of freight is considerable, amounting usually to fifty or seventy-five cars per day. This freight is mostly handled at night, leaving the road free during the day for passenger traffic.

At the Aylmer end of the line the company owns sixty acres situated on Deschesne Lake, a sheet of water three miles wide by twenty-seven miles long; an ideal spot for sailing and boating, thus forming a strong attraction for the Ottawa citizens. Indeed, the traffic has been far beyond expectations and the train service had to be increased until they are now running thirty-six regular trains each way per day, besides special excursion trains.



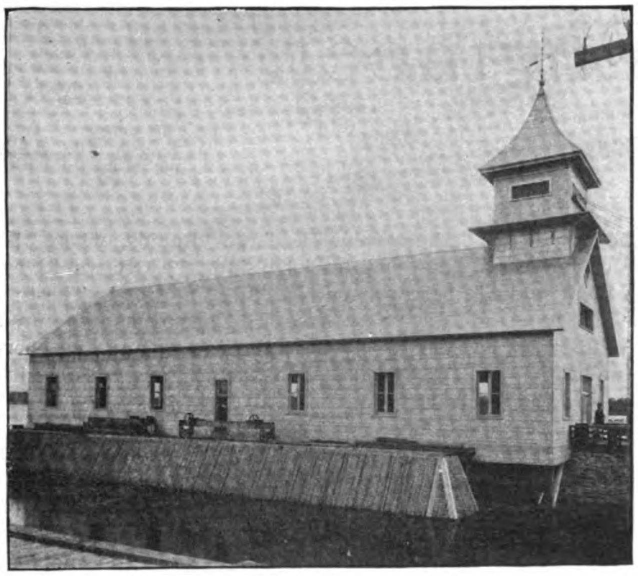
Electric Freight Locomotive Operating on Branch of Canadian Pacific Railway.

The power is obtained from Deschesne Rapids, where the lake of the same name empties itself into the Ottawa River, at a point midway between the termini of the road. The turbine wheels are of the "New American" type, manufactured by William Kennedy & Sons, of Owen Sound, Ont., and operate under a head of 9 feet. Four 60-inch wheels are now installed and space is provided for two more.

The electrical equipment of the power house consists of two M. P. 4-200-425 generators, built by the Canadian General Electric Company. For controlling the output of these machines there is a white marble switchboard, consisting of two generator panels, two feeder panels and a total output panel; all of the General Electric standard type and supplied by the Canadian Company. Besides these, there are three panels containing the "Barbour" water wheel regulator, by which the current output of the generators is automatically kept constant by cutting in or out dead resistance as the load varies on the line. By this means the speed of the machines is kept constant and the variation in voltage is held within a very close limit.

The car sheds and repair shops are also at Deschesne and are fully equipped with all modern appliances for handling and inspecting the rolling stock which at present consists of five closed cars and five open cars, besides a mail, baggage and express car and a locomotive. All the cars are mounted on double trucks, and are each equipped with two G. E. 1,200 motors with K. 21 controllers. They are said to be the finest electric cars in Canada. The closed cars are 42 feet long over all, and finished in mahogany throughout, the outside sheeting being also solid mahogany finish, in the natural wood.

These cars have extra large vestibules at each end, provided with seats for the accommodation of smokers, and divided from the main part of the car by double sliding doors. The



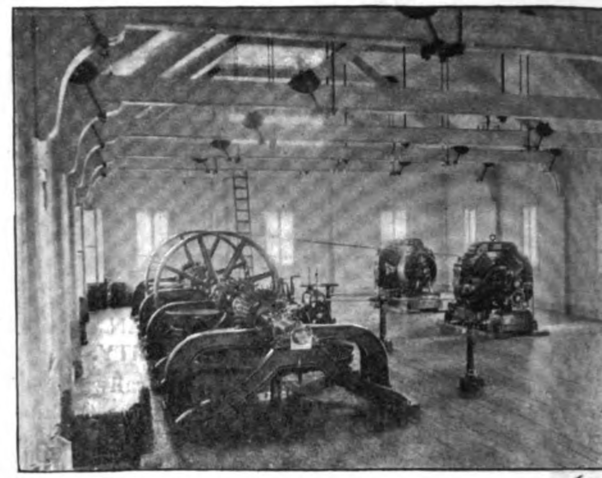
Power House, Hull & Aylmer, Can., Electric Railway.

open cars have thirteen benches, with reversible backs, and their finish and solidity are unsurpassed. All these cars were built and equipped at the Canadian General Electric Company's Peterboro factories, whence they were shipped complete ready for delivery on the track.

The locomotive is of particular interest, being the first of the kind operated in Canada. It weighs something over 20 tons and is provided with double trucks, each axle being equipped with a motor. As all the wheels are driven, full traction advantage is obtained from the total weight and a drawbar pull of 10,000 pounds can therefore be exerted, equivalent to the power of the average 35 or 40-ton steam locomotive. This was also designed and built by the Canadian General Electric Company.

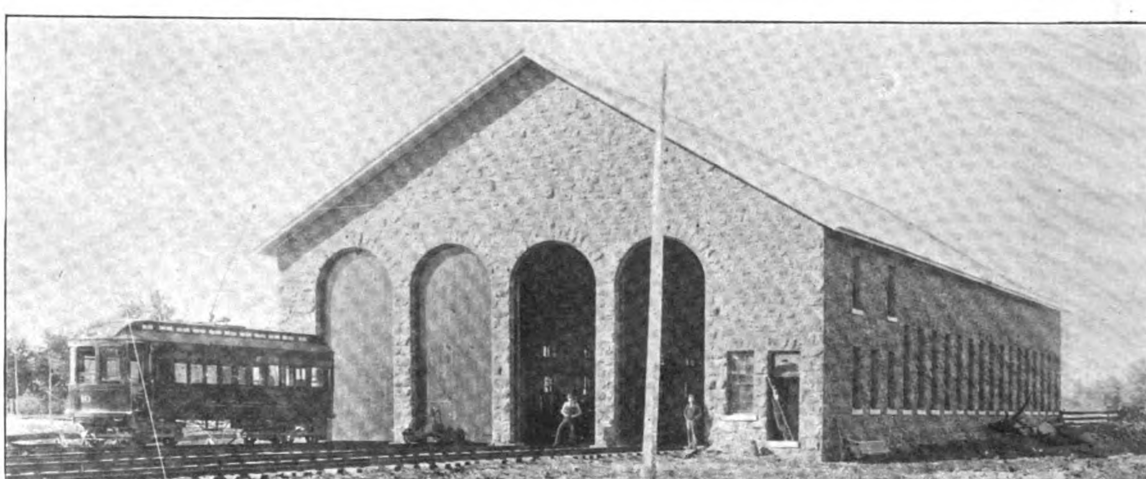
In equipping this road the Hull Electric Company have evidently constantly kept before them the maxim that the best is the cheapest in the end, and will no doubt reap the advantage by long life in their apparatus and small repair bills. The president of the company is Alexander Fraser; vice-president, W. J. Conroy; secretary-treasurer, James Gibson, and managing director, H. B. Spencer.

Besides operating the railway the company have also exclusive privileges for both private and public lighting in the city of Hull and the town of Aylmer, and for the purpose



Interior of Power House.

there is installed at the power house a 150 kilowatt monocyclic generator with a standard switchboard panel and equipment.



Car Barn, Hull & Aylmer, Can., Electric Railway, and Motor Car.

FIFTY-TWO NEW ELECTRIC CARS WRECKED IN WASHINGTON.

The hurricane that swept over Washington on the night of Tuesday, September 29, proved to be the most violent ever experienced in the District of Columbia. Buildings were thrown down and many losses reported of electrical property. Among the heaviest losers is the Metropolitan Street R. R. Company. Its large carhouse for the Ninth street branch collapsed over its handsome new cars, smashing fifty-two of them in a remarkable manner. The structure, which was a brick one, with a steel roof, had its girders so spaced that in falling over the cars, which were stored in four trains, many of them were cut in halves, each girder crossing four tracks. The carhouse is 80 feet wide and nearly 300 feet long and the cars, nearly all of which are hopeless wrecks, present an extremely sad appearance.

SPECIAL TROLLEY CAR ADVERTISING.

The Flint Company lead, as usual, with the novel idea of utilizing the cars of the Union Railroad Company, and have secured that privilege for advertising. Ahead of the monster Labor Day procession was a large trolley car decorated with flags and bunting, and covered with brilliant canvas, an-

nouncing Flint's grand gift sale—$1,100 given away in 10 grand prizes—a coupon with every purchase—easy installments, etc., while inside a large orchestrion discoursed classical and popular music to the multitude. It was conceded by one and all to be the most novel advertising ever seen in the city of Providence.—Providence "Journal."

THE ELECTRIC FOUNTAIN IN WILLOW GROVE PARK, PHILADELPHIA.

BY H. S. K.

THE electric fountain in Willow Grove Park, was designed by Mr. F. W. Darlington, Mechanical and Electric Engineer. The Park is a venture of the Traction Co. in the line of a refined resort and the nature of this venture can be inferred from the fact that Willow Grove has been called Philadelphia's Fairy Land.

The complete success of an electric fountain involves both science and art, and to their combined application is due the rapid developments made within the last few years. The fountain under consideration is an example of the application of the successful principles of the past and the introduction of new features.

One of the fountain's characteristics is its daylight attractiveness. An element of the landscape gardening, it is in beautiful harmony with its environment, and at the same time it has an independent charm of its own. The Fountain, Lake, Observation House, Sloping Banks, and Drive form a pleasing group; yet the Fountain is the striking feature. It stands out in the lake, surrounded by a low wall whose rounded corners are surmounted by diminutive columns. Within and higher is the second basin, whose bulging sides curve into columns that are capped with graceful vases. The pipes, jets and funnels are unobstrusive. There is a completeness about the daylight fountain that little suggests its latent possibilities.

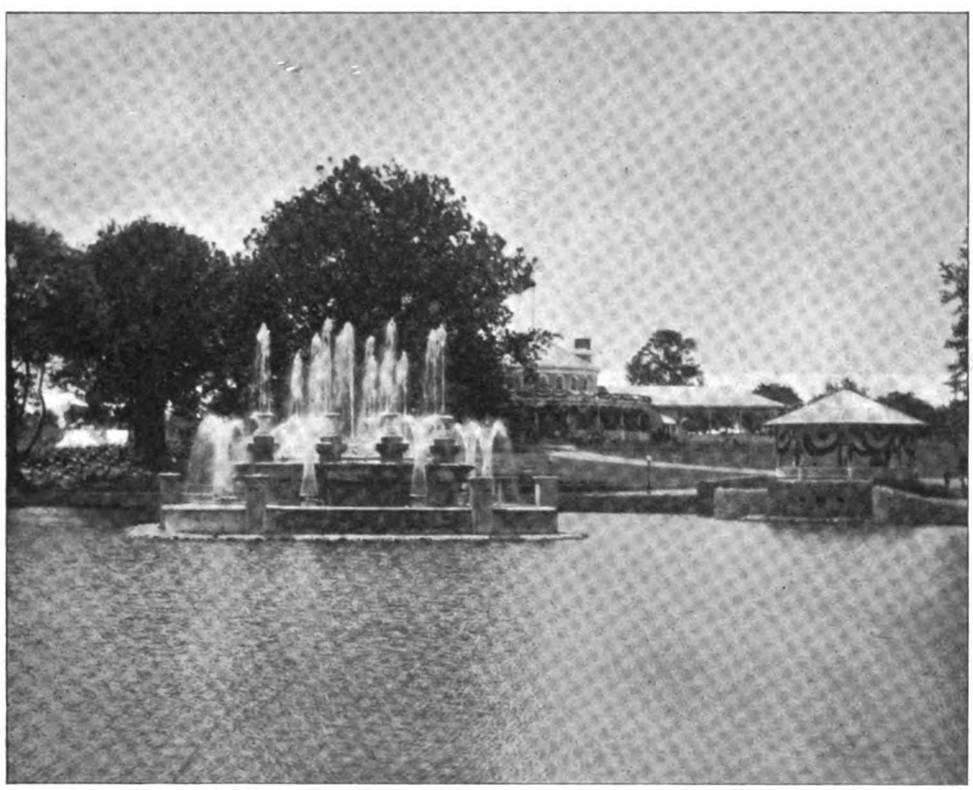
Electrically the fountain is built upon the principle of illuminating the jets in the direction of their length. The illumination is produced by lights concealed within the base. There is in reality a fountain of light as well as a fountain of water. Both light and water travel the same path, hence the illumination. The light passes through glass windows in the roof of the chamber beneath the fountain into sloping funnels whose upper ends clear the surface of the water. These funnels are surrounded with jetted pipes, and within each is a nozzle.

This method of illumination allows a simple solution of the color problem. A rotating color disc is interposed between each lamp and its window. But the illumination need not be limited to ascending water, for the upper cascade may have colored light thrown on it through windows in the sides of the second basin. Moreover the introduction of the fan opens up possibilities of scenic projection. Pictures can be thrown upon this screen from the controlling house on the shore.

In addition to being the source of light electricity is also the source of power.

The electric equipment consists of lamps, motors, and controlling devices. There are fifteen arc-lamps of the Rushmore Dynamo Works make. They are focusing and reflecting and of 8,000 candle power. There are two G. E. 2,000 motors operated by series multiple controllers. The motors drive the pump and get their power from the Traction Company's line. The lamp circuits are controlled from a marble switchboard.

The pump is of the Gould make and has a normal capacity of 1,000 gallons a minute, with sufficient margin to give 1,200 to 1,500 gallons at a pressure of 100 lbs., when necessary. It gives an average height of 100 feet to the streams, but can project the solid central jet to 150 feet. The pump is under complete control, which adds to the flexibility of the fountain.



ELECTRIC FOUNTAIN, WILLOW GROVE PARK, PHILADELPHIA.

A tunnel connects the chamber beneath the fountain with the basement of the controlling house under the pavillion on shore, where the motors and pumps are located. The water is pumped over and over again, for the supply is taken from the lake. The pump is controlled from the alcove, and from here the action of the fountain can be observed. In the alcove are also the main valves, the lighting switchboard, the twenty-four levers of fourteen positions each for controlling the water jets. The entire system is simple and flexible and, with so many variables, streams, sprays, lights, colors, and pressure it is not surprising that the number of effects that can be produced is legion.

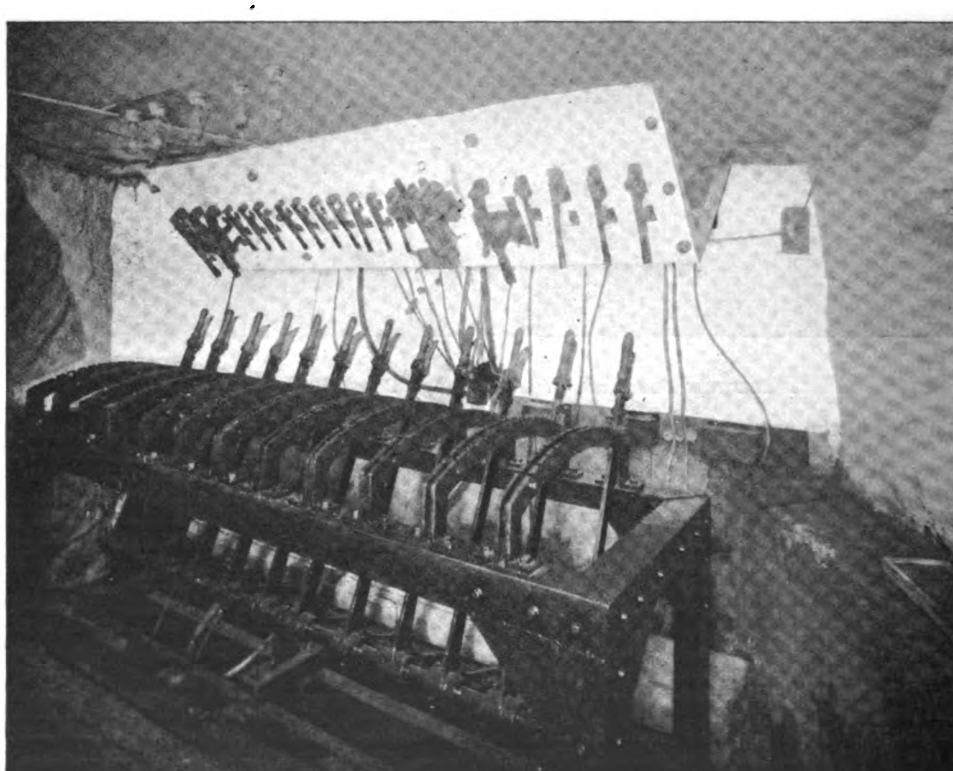
The fountain itself is simple in design, consisting essentially of a foundation and two basins. The foundation lies entirely below the surface of the lake and contains the chamber in which the lamps, the reflectors, and color devices are located. It is built of cut stone and is 44 feet square. The superstructure which it supports is built of iron, stone and brick and is octagonal in shape. The lower basin rises three feet above the lake and measures 24 feet across; it supports eight columns and contains eight light funnels. A big ring pipe encircles the entire circumference, eight smaller ring pipes surrounding the light funnels, and eight one-inch nozzles. The columns are appropriately decorated. The second basin rises

5 feet above the first and is ornamented with vases. It contains large and small ring pipes, light funnels, and, in addition, two big arched pipes.

ELECTRIC FOUNTAIN, WILLOW GROVE PARK, PHILADELPHIA.

to give massive spray effect. The nozzles of the little ring pipes are arranged for the wheat sheaf effect; and the one-inch internal nozzles are designed for columns. Both large

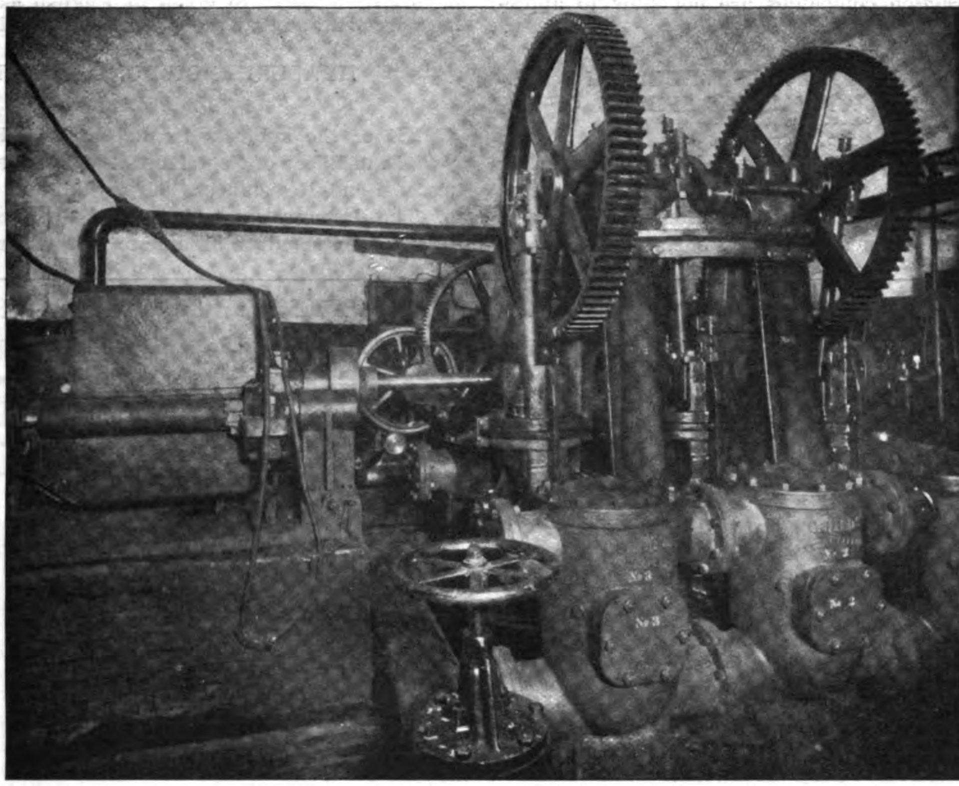
ELECTRIC FOUNTAIN, WILLOW GROVE PARK, PHILADELPHIA.



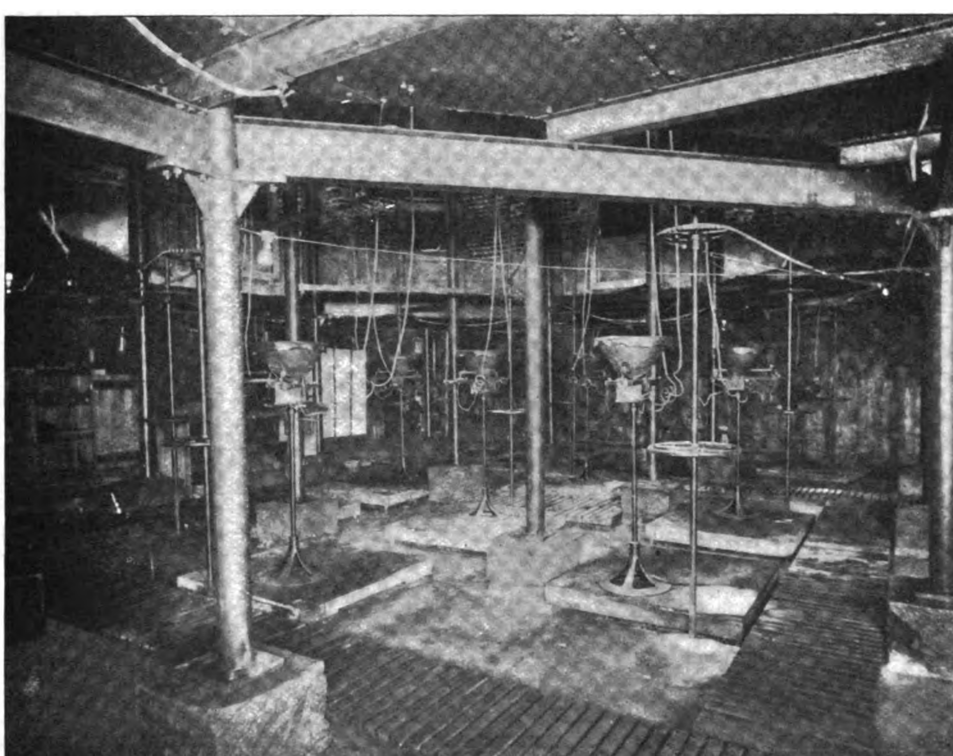
CONTROLLING APPARATUS FOR ELECTRIC FOUNTAIN, WILLOW GROVE PARK, PHILADELPHIA.

Since the artistic success of the flowing fountain depends primarily on the design of the nozzles, they have received special attention. The ring pipe in the lower basin is jetted and small ring pipes in the second basin are intended for spray effect and the design can be changed from time to time, thereby increasing the possibilities of the fountain. Six of

the big nozzles throw an inch and a quarter stream, and the middle one an inch and a half. The two arched pipes are jetted in such a manner that the entire screen can be illumi- red, and are operated from a rack. The rack is so constructed that the discs can be operated singly or in groups; consequently a multitude of combinations can be produced.



ELECTRIC PUMPS DRIVEN BY RAILWAY MOTORS, OPERATING ELECTRIC FOUNTAIN, WILLOW GROVE PARK, PHILADELPHIA.



PROJECTING APPARATUS IN CHAMBER UNDER FOUNTAIN, WILLOW GROVE PARK, PHILADELPHIA.

nated. Simplicity is also a characteristic of the color mechanism. The fifteen color discs are supported on vertical shafts, contain five colors, white, orange, purple, green and

The accompanying illustrations show the interior of the chamber below the fountain, the electric pumps and some of the innumerable phases of action into which the fountain can

be thrown. Of course the color effects must be left to the imagination.

This is Mr. Darlington's second fountain, as he also designed the one in Schenley Park, Pittsburg. Its success demonstrated possibilities that traction companies are not slow to appreciate.

CHART SHOWING REVOLUTION OF WHEELS AND DISTANCE TRAVELLED AT VARIOUS SPEEDS OF STREET CARS.

EVERY street railway superintendent and engineer, whether electrical or mechanical, is constantly called on to solve questions involving the number of revolutions of wheels of different diameters, distance travelled, etc., of street cars.

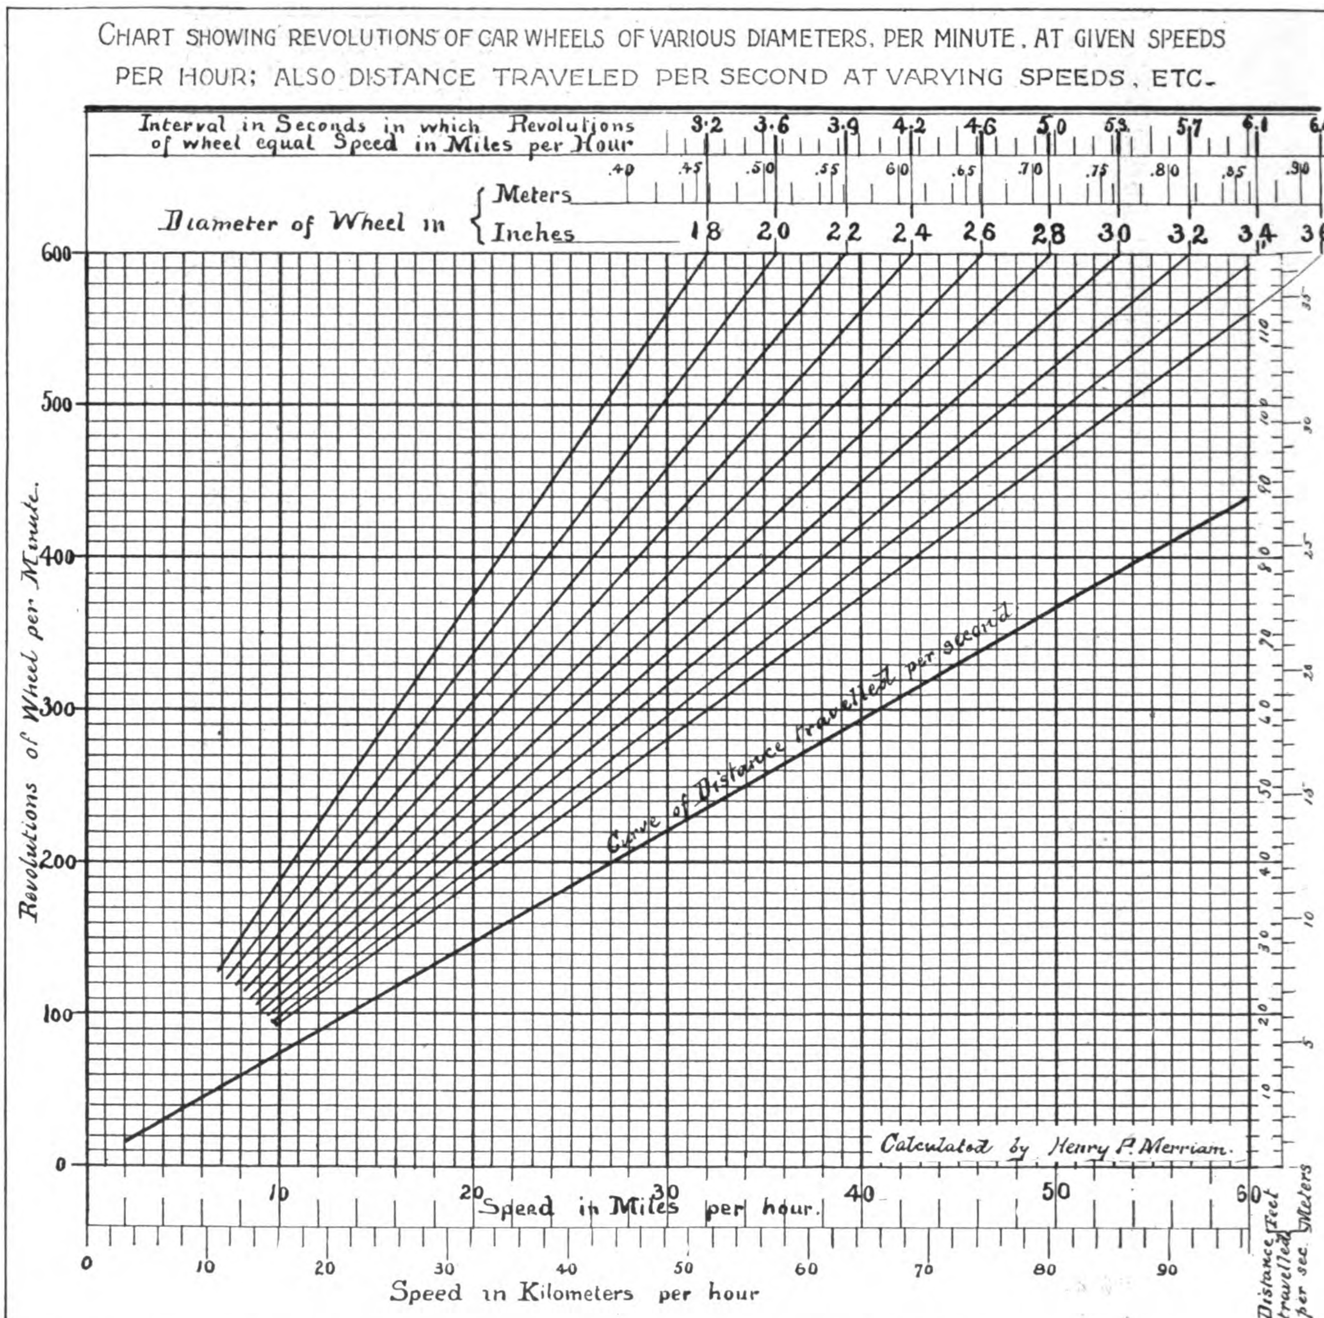


CHART SHOWING REVOLUTIONS OF CAR WHEELS OF VARIOUS DIAMETERS, PER MINUTE, AT GIVEN SPEEDS PER HOUR, ETC.

These points are of particular moment in considering the question of effective braking. Hence it is with special appropriateness that the Standard Air Brake Company, of New York, have included a chart giving this information in a neat folder to be distributed at the St. Louis convention this month.

This chart shows at a glance the number of revolutions of car wheels of different diameters, per minute, at given speeds per hour; the distance travelled per second at various speeds; the interval in seconds in which revolutions of wheel equal speed in miles per hour, etc. All linear distances and diameters of wheels are given in English as well as in metric measurement, so that the chart is applicable the world over.

MEASURING OF BOND RESISTANCES.

BY J. C. HENRY.

ONE of the subjects treated by The Electrical Engineer Data Sheet of September 2 (508, Sheet 3) is the Measuring of Bond Resistances. Three different ways are referred to. The first appears to be passed upon as generally impracticable; the second we assume to be the same as that described in The Electrical Engineer of July 1, as the writer's invention; the third seems to be theoretically the same as the second. Calling my instrument a differential ammeter, and the other a millivoltmeter, "having the zero in the middle of the scale," makes no difference in the scheme or in the results. The fact is, they are both differential galvanometers. They are both used to show at a glance what is going on in two separate cir-

cuits, and they are both used to compare the resistance of one section of track with another. Plan No. 3, however, has the advantage that the tests may be carried on by one person measuring but one joint at a time.

Our practice has required one man and two boys who take in four or more track points at a time. When trouble is noticed on either circuits we close in and make precisely the same connections as shown in plan 3. These methods originated with me. They are protected by Claims 1 and 2, Patent 540,054, of May 28, 1895.

That my statement and the invention may be better understood, permit me to trace out the evolution of the latter. The greatest inventions are those so simple that it is difficult for an outsider to see any invention in them. Although as in this case they are usually evolved in a very clumsy manner. In 1892 I applied for a patent, now No. 508,615, of November 14, 1893, on a distribution system where the track rails are reinforced by an insulated conductor connected to them at intervals, the object of this plan being to provide a shunt around rail bonds which might become injured and to offer an insulated path for that portion of the circuit which was inclined to leave the rails owing to poor bonds and thus prevent the injury to underground pipes, disturbing telephone circuits, etc. The general plan was to carry this supplementary wire on the span wire poles. While this plan was under consideration it occurred to me that by placing an ammeter in the supplementary conductor we could form some idea of what the current was on the track, and consequently determine the condition of the bonds. This looked like a very desirable scheme, but we were dealing with a varying current which caused a fluctuating resistance in the track joints, and we had nothing standard to compare with. Then it occurred to us to measure the current in two adjacent sections simultaneously. Assuming the chances of their both being defective to the same degree was very slim. Our arrangement at this time consisted of spring switches on the poles and a pair of portable ammeters to be inserted and read simultaneously.

The next step was to bring the two meters together by portable conductors. At this stage of the invention we learned we were not smart enough to catch the reading on both instruments when their needles were fluctuating. There being no such instrument on the market, we were compelled to experiment with and design one suitable, having but one needle controlled by two circuits. Now having the portable conductor and a single instrument we were enabled to dispense with the overhead shunt conductors, and thus put the method within reach of all roads.

Such is our "Resistance Detector" in its present shape, and now that I have exposed to the novice how inventions are made, I might save them lots of trouble by advising not to attempt to make them. It is so much easier to use the other fellow's, if it happens to be worth struggling for, owing to the loose patent laws and nefarious court decisions. He cannot stop you without spending a fortune and years of time. Then after the subject has been thoroughly ventilated, you may safely depend upon some one telling you how to do it in another way.

A NEW DAY SUMMER RESORT.

ONE more summer resort is about to be added to the large number already in the vicinity of Greater New York which have been made accessible by the adoption of the trolley system. Midland Beach is the name given to a portion of the southeast shore of Staten Island which is undergoing extensive alterations and improvements at the hands of the Staten Island Midland Railway Company, who are also extending their system to various towns throughout the interior of the island.

EDUCATIONAL.

UNIVERSITY OF WISCONSIN.

The catalogue of this Univerisity recently received mentions as special lecturers: W. E. Baker, of the Metropolitan Road, Chicago, on "Electric Equipment of Elevated Railroads;" John Lundie and L. L. Summers on "Motorcycle Tests;" R. H. Pierce, Chicago, on "Electric Storage Batteries from an Engineering Point of View." D. C. Jackson remains professor of electrical engineering, and B. F. Snow, professor of physics.

MR. C. E. MAGNUSSON, in the engineering department at the University of Minnesota, has won the $30 prize and gold medal offered by the Gillette-Herzog Company for original theses. His subject was "Specifications for an Electric Light Plant." There are three such prizes given annually on the award of a committee of engineers.

ELECTRIC LIGHTING.

THE DESIGN OF LARGE ARC DYNAMOS.

BY GEO. ALBERS.

WHATEVER the arc lighting station of the near future may be, it will not consist of a large number of small series dynamos, separately belted to a countershaft, nor will it consist of large constant potential, continuous current machines; nor will alternate current lamps probably be allowed. Designers have given much thought and experiment to the solution of the problem along these lines, but arc lighting has grown beyond their compass.

Recently inventors have sought to run a number of series circuits from the same dynamo, in parallel, or from independent windings overlapping on the same armature core. The first of these is the extreme of consolidation, opposed to the extreme of subdivision, which is the present method of running each circuit from its own little independent dynamo. The second is the first step toward subdivision, for now each series circuit has its own armature winding. The second step also has lately been proposed.[1] It is to divide the armature into segments and place the winding for each circuit on its own separate segment. This gives us much better latitude in the choice of regulators than does the multiple-series arrangement. Is it not possible that there is a practical limit, which just includes all the advantages of extreme subdivision, and at the same time gives us, from a single shaft and commutator, the high economy and small floor space of consolidation? It would seem that there is, and that the machine representing this limit must be an aggregation of units, each of which will have its own magnetic circuit, armature and field coils and regulator, but possesses its moving part in common with the whole station.

There is also a practical limit to the first extreme. For we cannot subdivide a continuous current and regulate it so that each parallel branch will be a good arc circuit, and we do not wish to send an alternating current to our lamps. So, if we are to have one large multiple series dynamo, we will be obliged to have separate commutator for each circuit, and to place our regulator either between the armature coils and the commutator, or at the commutator (as in the case of shifting the brushes). This prescribes that our dynamo shall be a multiphase alternator with the commutators for each circuit run in synchronism with it. They may be run by synchronous motors or by gearing them to the armature shaft, as Prof. Thomson proposes.

If an armature is to hold very many independent circuits, it must be so large that the dynamo will be multipolar. This usually involves for each commutator, several pairs of brushes connected in parallel, or elaborate cross-connections in circuits of high potential, or running the commutators at a higher (synchronous) speed than the main shaft. In the third case each commutator must have as many collector rings as segments, and, to avoid the large number of collector rings on the main shaft, the naturally bulky armature should be stationary. Designers of arc machines seem to have overlooked the fact that because the armature is stationary it does not follow that the field magnet shall rotate.

About a year ago, in a paper read before a local society,[2] the writer proposed two types of machine growing out of the above reasoning. This paper was almost immediately followed by the issue of Patent No. 548,406, showing that Prof. Elihu Thomson had previously applied the same ideas, including even the details of regulation. Yet, in one of these two types, the manner of applying them differs so greatly from anything that has yet been published, that it is described here as an example of the above mentioned, extreme practical limit of subdivision of units for a large station. In the original paper it was proposed to install a commutator for each circuit; the several commutators to be mounted on the shaft of a synchronous motor; but the complex commutator here described seems to be a more logical accompaniment to this design.

Figs. 1 and 2 show an electric light station, in which, for the purposes of this article, we will speak of the individual stators, 1, 2, 3, 4, 5, 6 and 7, as separate dynamos. Thus 1 is an incandescent "dynamo" and the other six are arc "dynamos." The paths of the magnetic circuits are readily seen in Fig. 2. From the left half of Fig. 1 one limb of each field magnet with its accompanying pole piece has been removed, so as to show the rotating part. The various parts are: A, A, etc., field magnets; P, P, etc., pole pieces; C, C, etc., rotating

[1] By Elihu Thomson, in Pat. No. 548,406, Oct. 22, 1895.

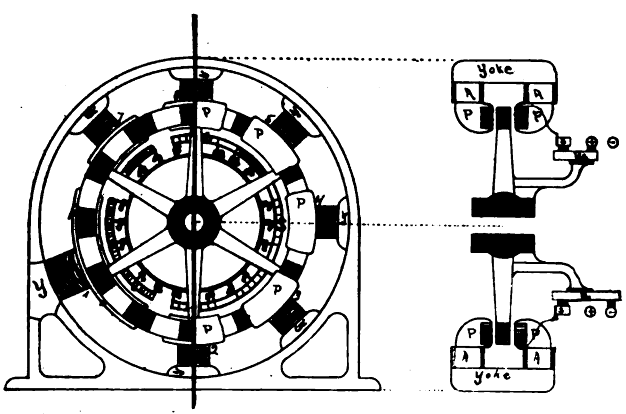
[2] The Electrical Seminary of Kansas University.

keepers; the armature coils, or, more properly, the induced coils, not shown, are laid directly upon the laminated pole pieces, or in radial grooves in their laminations; S, S, etc., commutator segments; B, B, etc., rotating brushes; + and —, collectors or terminals.

In the operation of the machine, the passage of a keeper is accompanied by a wave of electromotive force in the several coils in succession; we may speak of the crest of the wave as positive and the hollow as negative. The moving brushes make contact with the stationary commutator at points corresponding to the crest and hollow of each wave, and also make contact with the stationary collectors. Each brush is electrically independent of every other, and serves merely as a connecting link between the commutator and a positive or a negative collector, during the short time that it occupies in passing any given dynamo. In this manner it makes the round of the station. To connect with the two collectors of each machine there are arranged alternately "long brushes," B_1, Fig. 2, and "short brushes," B_2. They are alike in the parts that make contact, but differ in the length of the piece that joins the part bearing on the commutator to the part bearing on the collector, so that every alternate brush shall slide on the collectors located furthest from the commutator, while those between shall slide on the nearer ones.

The collectors differ from the familiar collector rings only in that they are not complete rings, but are divided into arcs of the circle of revolution which the brushes make. Their angular length is equal to that of the pole pieces of the several dynamos to which they belong. Thus, each dynamo has its own pair of collectors which form its positive and negative terminals, each of which is at all times in contact with at least one brush.

The number of keepers is 50 per cent. greater tnan the number of dynamos, or, more correctly, than the number of angular units into which the station is divided. (In the figure the incandescent machine occupies two angular units.) This keeps the magnetic circuit complete at all times, but, in order that its reluctance shall be constant, the pole pieces should be cut away slightly, near their edges. For, when one keeper is just leaving the space between a pair of poles, and another is just entering it, the magnetic circuit is completed through two keepers, and, therefore, the air gap should be a little greater near the ends of the space than in the center.



Figs. 1 and 2.—Albers Composite Inductor Dynamo.

Though the arrangement provides for laminated pole pieces, it should not be inferred that a large amount of iron is subjected to hysteresis loss; for the total depth of laminated iron, including that in the two pole pieces and the keeper, should be less than the diameter of the armature of an old style arc dynamo. Moreover, the direction of magnetization in the keepers need not ever be reversed; for it is convenient to have all the north poles at the front of the "complex station" and all the south poles at the rear, or vice versa.

In the armature of any continuous current dynamo, the current divides in passing from brush to brush, and goes through the two halves of the armature in parallel; in this dynamo these halves are stationary and independent, being fastened on the two opposite polar faces. They may, therefore, be used to supply different arc circuits. In this case, however, our composite electric light plant must have two commutators instead of one, as described above. This is a step away from extreme subdivision but, in practice, it is a good step to take.

Such a station will have a very large output in proportion to its size. Suppose, for example, we wish to supply current for 1,600 lights. If installed according to the so-called modern method, with sixteen 100-light dynamos belted to a countershaft, compactly arranged by belting in tandem in pairs, and allowing just space enough to get around each one, the floor space required for the dynamo room would be not less than 35 by 50 feet, and in practice would usually be very much more. On the other hand, if such a composite station as is here described were used, assuming the polar breadth of each dynamo to be two feet, and the space between poles of neighboring dynamos to be one foot, and that eight 2-circuit machines be employed, the diameter of the rotating part would be eight feet, and the whole generating plant would be encompassed within a circle, in a vertical plane, about twelve feet in diameter. Moreover, each additional 200-light unit would increase the radius of the plant but six inches.

We have yet to speak of regulation. The stationary armature enables us to use several methods not otherwise possible. In the composite station we are able to use any means of regulation practicable on any arc machine. One apparent and partial exception to this rule is the case of shifting the brushes. If that part of the commutator which belongs to any given dynamo has a clear space on each side of it, as shown on the left half of Fig. 1, so that it may be rotated through a short arc about the common center without striking the parts that belong to its next neighbors, on either side, then we may regulate by shifting the commutator, which is obviously the same thing, so far as regulation is concerned. If, on the other hand, we find that these blank spaces cause serious "jumping" on the part of the brushes, so that we are obliged to fill each one with a broad dead segment, as shown in Fig. 1 on the right, which will probably be the case, we will be deprived of this method of regulation.

There is, however, still another way of accomplishing the electrical equivalent of shifting the brushes; it is to insert choke coils with movable cores into the circuit on its way from the induced (armature) coils to the commutator segments—retarding the waves of current by the coils answering the same purpose as shifting the brushes forward. Where there are but few segments, this method of regulation is very convenient. With most styles of winding, only half as many choke coils as segments will be required.

Imagine a row of from three to six choke coils, according to the number of segments, with movable, pointed, laminated iron cores fastened to a common bar at their large ends. The arrangement of cores will resemble a rake; now suppose that the rake is pivoted at a point in its handle, so that it is free to swing, like a pendulum, in the direction that the teeth point. As the current in the coils increases, the cores will be drawn further in, thus increasing the choke effect. By properly choosing the shape and weight of our cores, this regulator will keep the current constant within ordinary working limits.

We might replace the choke coils by constant current transformers, or we may regulate by automatically cutting in or out induced coils, and even reduce armature resistance on light loads by throwing the two opposite sides of the dynamo in parallel through one commutator.

Indeed, the flexibility of this system exceeds in some respects that of the old way of energizing each circuit by its own separately belted dynamo. With but one common moving part we retain the ability to run continuous and alternating current dynamos of as many types as we desire, including constant current and constant potential, with open coils on some and closed coils on others, with different numbers of commutator bars, and any variety of regulators.

A departure from this extreme must sacrifice something of flexibility, yet, as a rule, this is not objectionable in practice. A step toward the conventional form but retaining the composite idea, might in brief be as follows: Let the magnetic circuits and general form of the machine be the same as in the diagrams, and let all dynamos be arc machines and exactly alike. Let the rotating part carry the armature coils in one continuously overlapping winding around the whole circle. This winding need not necessarily be "open coil," nor is iron really necessary in the magnetic part of the armature. Give each dynamo (stator) its own pair of stationary brushes. If two circuits, one from each side of the armature laminations (if there are any), are to be taken at each dynamo, then the station will have two rotating commutators, exactly analogous to the two stationary ones mentioned in the description of the extreme type.

If it is true, as assumed at the outset, that the arc lamp of the future will be actuated by a continuous current, then we may say, with a good degree of confidence, that hereafter designers of very large arc dynamos should confine their efforts to the fertile field within the two rather near extremes, of which one is represented by the multiphase alternator with a separate commutator in each circuit, and the other by an aggregation of nearly independent units as in the inductor above described.

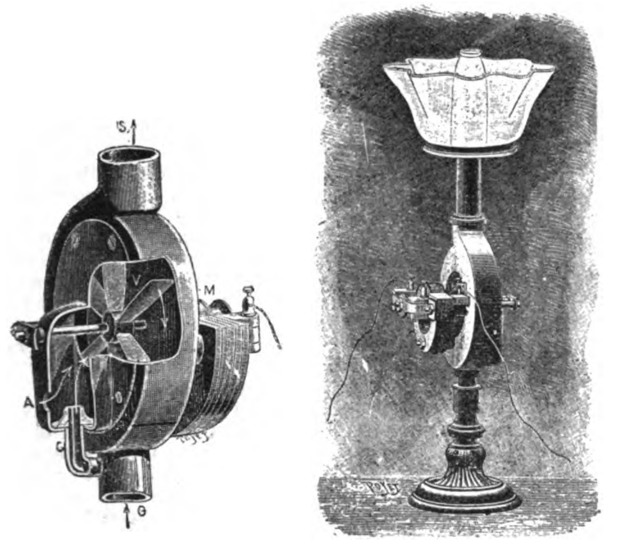
NEW LONDON, CONN.—The New London Street Railway Company proposes to introduce electric power into the city, supplying from its circuits.

THE DENAYROUSE GAS BURNER.

AMONG the latest aspirants to lighting honors and an alleged rival to the incandescent lamp is the Denayrouse burner, which may be described as a sort of combination of the Welsbach and the old "moderator" oil lamp. In the Denayrouse burner, to which we have already called attention, the object aimed at is to establish a thorough mixture of the air and gas before it reaches the point of ignition so that it may develop its highest heating capacity.

The engraving, Fig. 1, taken from "L'Illustration," shows the Denayrouse mechanism in detail, and Fig. 2 shows the lamp complete.

The apparatus consists essentially of a bronze or brass box



FIGS. 1 AND 2.—THE DENAYROUSE INCANDESCENT GAS BURNER.

in which revolves a fan V, keyed upon an axle that passes through the box. The axle is revolved by means of a small electric motor mounted upon one side of the box. Upon the axle is arranged a speed regulator. The air enters at the bottom of the box at G, and the gas at the center at A. The exit of the mixture takes place through a chimney, S, arranged at the top and to which is fixed a luminous mantle. The apparatus operates as follows: The motor revolves the fan at about 1,200 revolutions a minute. There is thus formed a strong draught of air, which mixes with the gas that enters at the side. The ignition occurs at the upper aperture of the chimney.

It is claimed that the Denayrouse burner consumes 4.4 volumes of air to one of gas, the theoretical perfect combining ratio being 5.5. A writer in "L'Illustration" by an elaborate calculation shows that for the same money, the Welsbach gives four times, and the Denayrouse nine times as much illumination as the butterfly burner.

WILMINGTON, DEL., CENTRAL STATION.

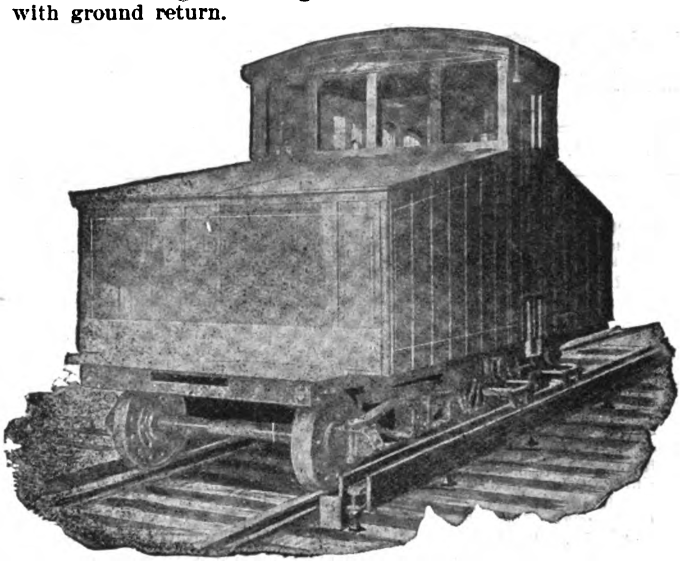
The Wilmington, Del., City Electric Company are reconstructing their old central station, and adding a small annex for storerooms and offices, next to the engine room. The work is being done under the supervision of Mr. C. R. Van Trump, the manager and electrical engineer. The steel work has been supplied by the Edge Moor Bridge Works, of Wilmington. The engine room is one story, 42 feet by 128, with a gallery at the end, which will be the superintendent's office, with the switchboard immediately in front. This board is of marble, and of non-combustible material throughout. The boiler house adjoining is also to be of steel construction with brick partitions built between, carrying the roof. There is a steel wire tower in front which carries the lines directly to the poles from the sides. The new building will not be elaborate in any way, but solid and substantial. No new apparatus will be installed.

CLARKSVILLE, TENN.—The Clarksville Electric Light Company have made an assignment; liabilities $50,000, assets $8,000. H. C. Stacker, secretary, is made assignee and is directed to wind up the company's affairs within ninety days by private or public sale.

NEWS AND NOTES.

STORAGE BATTERY LOCOMOTIVE ON THE N. Y. ELEVATED RAILROAD.

AFTER a long period of quiescence the N. Y. Elevated Railway management have again taken up the consideration of equipping their roads with electric power, and only recently the president of the road made a tour of inspection among the principal railway apparatus shops of the country, to gain further information on the subject. The experiment to be immediately undertaken is in many respects a novel one, involving an electric locomotive carrying a storage battery. The first experiments beginning this week will be carried out on the Thirty-fourth street branch of the Third avenue line, running from Third avenue to the East River, a distance of about a quarter of a mile. The track construction is similar to that employed on the Lake Street elevated road in Chicago, a third conducting rail being laid outside the two main rails with ground return.



THE STORAGE BATTERY LOCOMOTIVE ON THE NEW YORK ELEVATED RAILROAD.

The locomotive, which is illustrated in the accompanying engraving, is mounted on the standard elevated railway trucks, measuring 22 feet 9 inches over all outside the drawbars, with 38-inch drivers. It is equipped with two 125 h. p. motors. each of the General Electric 2,000 type, similar to those employed on the Nantasket Beach Railway. The storage batteries are situated in the two wings on either side of the cab in the center. They consist of 256 cells, placed all in series, and weighing 80 pounds each, thus making the total equipment weigh 10 tons. Each of the cells contains seven plates, three being positives of the Planté type, and four Chloride negatives.

During operation the cells are constantly in parallel with the line, whether the train be in motion or not. Current is supplied to the line at 500 volts, the power being supplied from the factory of the New York Electric Equipment Company, which is within a few hundred feet of the line of the road.

LEGAL NOTES.

A TELEPHONE DECISION ADVERSE TO DRAWBAUGH.

The Court of Appeals of the District of Columbia on Sept. 29 rendered a decision in the case of Daniel Drawbaugh, who was refused patents for certain alleged new improvements in telephone transmitters.

The decision was written by Chief Justice Alvey, and affirms the decree of the Commissioner of Patents. The case was divided into two parts and argued before the court last November. The decision was withheld because of the application of Mr. Drawbaugh to Congress for relief. This application was withdrawn by Mr. Drawbaugh, whose petitions for patents were filed in 1883 and 1884.

The Court of Appeals held that Mr. Drawbaugh never was the inventor of the transmitter.

PRESENT STATUS OF ELECTRIC POWER TRANSMISSION.

ALTHOUGH somewhat slower to obtain that lasting hold on the engineer as well as the public that the electric light obtained almost instantly after its launching into commercial practice, the transmission and distribution of power by electricity has nevertheless established itself with equal firmness. Indeed, it may now boast of having even more zealous adherents. The statistics of transmission and distribution plants, both local and long distance, of the entire world, if they could be got together, would make a formidable demonstration of work accomplished in a comparatively short time. It is just this latter factor, the shortness of time in which the work has been done, that has prevented that crystallization which is the result of slow evolution in most of the other branches of engineering, and hence it was eminently fitting that Dr. Louis Duncan should select as the theme for his second inaugural address as president of the American Institute of Electrical Engineers, the present status of electric power transmission and distribution. As a brief review of a wide field of work, Dr. Duncan's address is an excellent condensation of current practice with comments that will not fail to impress themselves on all interested in the handling of the electric current, whether as engineers or as commercial exploiters.

Taking up the subject from the latter standpoint, more particularly, the fluctuating load on practically all central stations has deservedly received particular attention by Dr. Duncan, and if we read him aright he sees in the storage battery the means for avoiding many of the losses which the general conditions of current distribution have heretofore involved. This is the inevitable conclusion derived from the experience of extended work abroad, which we are glad to note is slowly but surely being taken advantage of in America. A few of our lighting stations have made a good start in this direction, but the small ratio of the continuous current to the alternating current stations in the United States, would indicate that the largest field for this auxiliary lies in the direction of electric railway work. The relative advantages of the location of storage batteries within the station as compared with their placing at centers of distribution is another point touched upon. There can be little doubt that so far as economy of copper is concerned the latter plan is to be preferred, but this would militate to some degree against the strong argument which Dr. Duncan makes for concentration of apparatus in single stations, as compared with the present practice of locating a number of stations at the centers of distribution, as now practiced in low tension distribution systems in our large cities. While theory may bear out the argument for concentration, actual practice does not always; in fact, rarely, confirms it, so far as low tension work up to 220 volts is concerned. Take the case of the great Duane Street station of the New York Edison Company. This station is located within little more than half a mile either way of the water front, and yet careful calculations showed that the economies of operating the engines condensing and the saving in haulage of coal and ashes were not sufficient to overbalance the interest on the investment required by the additional amount of copper which would have been necessary owing to the displacement of the station from the center of distribution. It is conditions like these that frequently compel the adoption of methods apparently at variance with good practice.

The views which Dr. Duncan holds on electric railway work are of particular interest at the present moment when roads are branching out into territories and covering distances scarcely contemplated five years ago. Fifteen mile railway circuits are not at all uncommon, while twenty and thirty mile lines are being operated at the present time. If the operating voltage at the motor is to be maintained at approximately 500 volts, and this will in all probability remain a fixture, something must eventually be done to increase the voltage at the station for the long feeders, if excessive investment in copper is to be avoided. The booster and rotary current transformer have made but very little progress, while the storage battery as a remedy has, to our knowledge, been applied in but one or two instances of this kind, albeit with marked success. It may be looking far into the future, but the alternating system applied to street car service would remove many of the troubles now to be contended with in the drop of line potential on long feeders. That railway companies will have to consider this problem more seriously at no very distant date is apparent, and Dr. Duncan's conclusions on the subject will no doubt have their proper influence on the selection of the methods to be employed.

As regards methods of long distance distribution, if the results of actual practice constitute a valid criterion in this

case, it would seem that the three-phase system is decidedly in the ascendancy. The arguments adduced in its favor have thus far given it precedence, but without desiring in any way to detract from its merits one cannot help feeling that the system is still in a certain sense on trial. Perhaps as good a trial as it will ever have is now rapidly approaching consummation in the Niagara-Buffalo transmission of a preliminary 5,000 h. p.. What is the limit of potential is a question which Dr. Duncan's statistical table brings out in strong relief. The alternate current advocates will certainly extract comfort and encouragement to further efforts in contemplating the success of a 15,000-volt continuous current transmission, but Dr. Duncan has placed the present practical limit at about 20,000 volts, with everything beyond that as experimental. In most discussions of this branch of the subject it appears that one factor is not given the consideration which it deserves, and that is the climatic influence on the insulating properties of the line. Insulators have been and can be produced which will stand 100,000 volts on test under the dry laboratory roof, but when mounted on a pole, other conditions are to be reckoned with. We take it that much of the success of some of the long distance transmission plants in the West is to be credited as much to the dryness of the climate, as to the insulators. It is for this reason that we shall watch with peculiar interest the Niagara-Buffalo transmission, where the conditions are such as the most ardent antagonist of electric transmission could wish for.

There are many points in Dr. Duncan's address worthy of comment, but we must content ourselves with a closing reference to his statement that alternating current lamps are not increasing in number. We do not know on what information this statement is based, but would like to know whether it can be confirmed, if it is so. Far from its remaining stationary, we believe that the alternating arc lamp is making relatively greater strides than the direct current lamp just at this time. Perhaps our lamp and carbon manufacturers can shed some light on the subject, as indicated by their sales' books.

SOUND ELECTRIC LIGHTING ENTERPRISES.

THESE have been days to test the financial soundness and endurance of every enterprise. Not only has the country gone through a prolonged course of depression and disaster, but in the hour of extremity there have arisen counsellors to prophecy that the way back to prosperity is to scale down indebtedness in the cheap dollar, and we venture upon another risky economical experiment as eagerly as though there had not been enough lately to last an industrial people through one generation.

The ordeal of hard times has perhaps been hardest for new and young industries like the electrical, which in the period of easy money have invited large expenditures only to find that the moment of their maturity is beset by contraction of trade, lack of confidence, and general uneasiness or suffering. That electric lighting and railway companies have come through so well is striking, but to judge the profitableness of a young Florida orange grove just after a uniquely hard frost had nipped it, would scarcely be fair; and electric light and power plants, like such groves, still have their best years ahead of them, when conditions will be more favorable and when better methods have increased their capacity and productiveness.

That such is the opinion of very competent judges is evidenced by the recent financial operations of the Chicago Edison Company, noted recently in the newspapers and now confirmed by President Insull on his return from England. The facts are simply remarkable, and are full of encouragement. The company has made a $6,000,000 issue of mortgage bonds, at 5 per cent. gold, running 30 years, but redeemable at par, at the company's option in 15 years. The issue this year is $3,500,000. The company has outstanding at the present time $2,500,000 at 6 per cent., which will be exchanged for the new in part, a small amount being taken up and paid off in cash. Mr. Insull while in England sold $1,200,000 to a syndicate of London bankers, at a price just around par, their intention being to issue these bonds on the London market. The remainder of the bonds will be used from time to time as the Chicago business grows, and we presume that the same parties have first call on them.

This London sale is the more noteworthy in view of the fact that almost all of our securities have been in utter disfavor abroad because of the silver agitation; and another noticeable thing is that they were sold direct, without the intervention of New York, or even of Chicago, banking houses. The reason must be looked for in the belief in Mr. McKinley's election, and perhaps equally in the high class of the security, the net earnings above all operating expenses being, we have understood, more than three times the total interest charges of the $3,500,000 now being placed, or exchanged. The expert report on the company's system came from the careful hands of Mr. H. A. Foster, and the financial report was made by Price, Waterhouse & Company, the celebrated London accountants.

We have secured these details because, as we have said, they are full of encouragement for everybody who is doing good work in the electric lighting field, and who, rather than flouting foreign opinion, likes to see this country stand high in the esteem of the world. We have by the way, heard pessimistic sentiments as to the future of Chicago, whose financial troubles, postponed by the Columbian Fair, have been none the less stringent and severe in the long run; but here is well-founded evidence of belief in her continued growth and great future. Moreover, we must infer that with returning conditions of prosperity under a sound money regime, European bankers will realize that some of the "best things" are relatively small local securities in America, of this character. Such securities are, we imagine, practically unknown to-day in a market like London, which nevertheless absorbs similar securities from all over the world. The price is to us, little short of astounding; and if a higher price has ever been paid by a syndicate for a block of electric lighting bonds in this country, we shall be very glad to record it.

LITERATURE.

JULIUS CAHN'S OFFICIAL THEATRICAL GUIDE.—By J. Cahn, Empire Theatre Building, New York. Cloth, ill., 600 pages. Price, $1.00.

This is a most useful and interesting directory, one of the best we have ever seen. It gives each city, with its population, newspapers, hotels, etc., and a great mass of data in regard to the staff of each theatre, size, and other details. We are glad to note that a great number of theatres now have an electrician on the rolls and have large plants to be looked after; in fact, electricity is one of the most important adjuncts. The type is clear, the paper good, the arrangement of the information helpful and clear, the book as a whole very handsome. Its mere business contents are relieved by some fine portraits of theatrical stars, pictures of theatres, and railroad maps. The cover is strong and ornamental. Altogether Mr. Cahn is to be heartily congratulated on his first issue, which leaves only one thing to be desired—the next.

THE X-RAY. By Dr. W. J. Morton and Edwin W. Hammer. New York: Am. Technical Book Company, 1896. Illus. 196 pp. 12mo. Paper, 50 cents; cloth, 75 cents.

This unpretentious but striking book is one more proof of the intense interest felt in the discovery made by Prof. Röntgen. No other scientific pheunomenon has ever aroused so much immediate curiosity or been followed by so much immediate repetition of the experiments. In the present instance the value of the book is enormously enhanced by the fact that its chief author writes on the subject from the inside. Dr. Morton has not only been a zealous and alert student of electricity all his life, and a pioneer inventor in many of its fields, but in his application of electrical methods to his own profession he has been brilliantly successful, standing foremost to-day among the elctro-therapeutists of the world. It is obvious that the X-ray would make an irresistible appeal to one who is alike an expert electrician and a skilled physician, and it is matter of history that Dr. Morton was the first man in this city—perhaps in America—to test the Röntgen discovery. Since that time, his own work with the ray has attracted universal attention and his wonderful loan exhibit of cathodographs at the Electrical Exposition in May was a center of attraction to all, the praise of such men as Mr. Edison being the heartiest. This book, therefore, records Dr. Morton's own observations, studies and theories, in simple language, and throws out any number of valuable ideas as to uses in surgery and physiology. The accompanying "halftones" of his cathodographs, printed on plate paper, cannot be too highly commended.

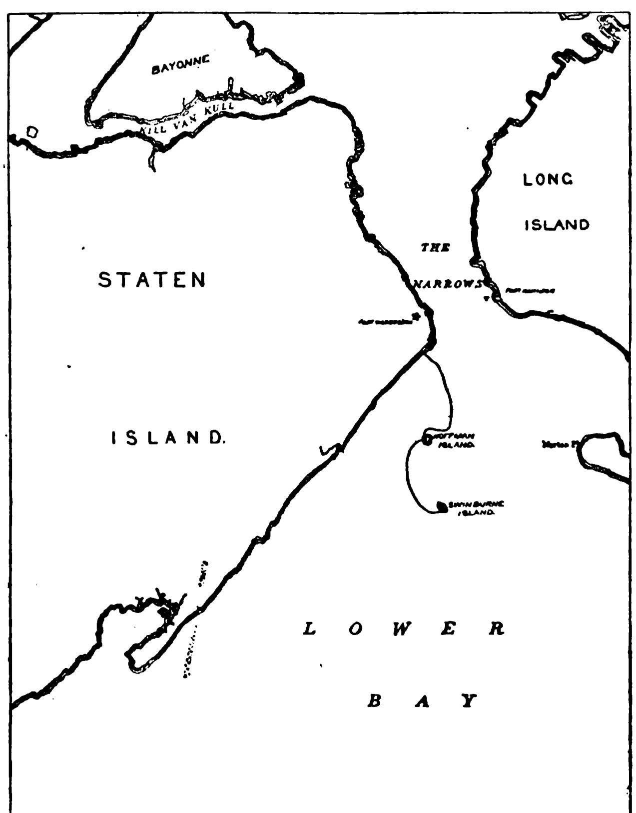
It was felt, however, that as this book would fall into the hands of many people not familiar with electricity, some useful information might be imparted leading up to the methods of producing the ray. Here Mr. Hammer's aid has been judiciously applied, and thus as the result of the collaboration the introductory part of the book serves as a very handy little guide to electrical principles and facts. There is also much that is pithy and pointed in regard to the bearings of photography on the subject. The book is quite handsomely got up.

TELEPHONY AND TELEGRAPHY.

THE NEW YORK QUARANTINE SUBMARINE TELEPHONE SERVICE.

ONE of the most important and interesting of the telephone services recently installed is that which is intended to meet the necessities of the quarantine system of New York City, as now established on Swinburne and Hoffman Islands at the entrance to the Harbor, in the Lower Bay. By means of the submarine cable and the telephone, these islands are now in communication with the mainland, so that not only the local quarantine headquarters can be reached directly and instantly, but any part of the country within the network of the Bell long distance telephone wires.

Few citizens of the city of New York, in fact very few citizens of the State of New York, are familiar with the situation and purposes of these islands, occupied by the State Government for quarantine purposes, situated as they are in the Lower New York Bay, almost, one might say, in the Atlantic ocean. These islands were, until a quite recent date, completely isolated from the world in general, no communication being had with the mainland except by steam vessels under the special control of the State Commissioners of Quarantine.



ROUTE OF CABLE CONNECTING HOFFMANN AND SWINBURNE ISLANDS WITH STATEN ISLAND, NEW YORK HARBOR.

After the experience of a few years ago with the importation of cholera, the Commissioners of Quarantine busied themselves with the improvement of the islands, and the service in general. Finding great advantages would be had by being in a position to have instant communication with the various officers in charge of Hoffman Island, devoted to detention and the examination of the suspected cases arriving from foreign ports, and with the officers in charge of Swinburne Island, devoted to the hospital service for the treatment of such cases as may have developed of a contagious or infectious nature, they decided upon installing a telephone system which would give direct connection with these islands.

After deliberation, the commissioners, seeking to obtain the best system possible, submitted their requirements to the manufacturer of Kerite cables, requesting that a plan be submitted whereby these islands might be connected one with the other, and with the mainland, by submarine cables sufficient to give them a service which would make instant communication possible between the islands and mainland, with the Health Physician's Office, situated at Quarantine Station, Staten Island, with the Commissioners' Office, situated in New York City, and with the State Government Office, at Albany, New York, together with such points as might be deemed necessary to reach by long distance telephone throughout the State.

After careful survey of the water surrounding, and the demands which would be made upon the cable for the purposes mentioned, the Kerite people submitted plans which were accepted, manufacturing and successfully placing in position special submarine telephone cables between the islands as mentioned and the mainland. The entire length of cable required is approximately 3½ miles, constituting one of the longest, if not the longest, submarine telephone cables (considering the capacity which is now in service) in the United States.

These cables having been successfully laid, were placed in connection with the system of the New York & New Jersey Telephone Company, giving private metallic circuit between Swinburne Island and Hoffman Island, Swinburne Island and Quarantine Station on Staten Island and trunk line, Swinburne Island to the central station of the N. Y. & N. J. Tel. Company at Tompkinsville, Staten Island, also Hoffman Island private metallic circuit between Quarantine Station, Staten Island; and trunk line service with central station N. Y. & N. J. Tel. Company at Tompkinsville, Staten Island.

This installation with the connections having been tested, was found to be remarkably perfect, and to give the most satisfactory service, reflecting great credit upon the foresight of the present Commissioners of Quarantine, upon the manufacturer of the Kerite submarine cables, and upon the N. Y. & N. J. Tel. Company, whose officials took active interest in aiding to make the installation one of the most perfect in this section.

The situation of the islands, together with surrounding waters showing the route taken in laying of cables will be observed in the cut accompanying this article. It is evident that in case of emergency, the islands are now in a position to summon immediate advice or assistance; while in case of contagious or infectious disease, the necessity to touch the shores of the two islands, or even approach them within hail, is reduced to a minimum.

ALLEGED SUBMARINE CABLE INTRIGUES RELATING TO SOUTH AMERICAN SYSTEMS.

THE project to connect the United States with Hayti by a direct line of telegraphic cable, in which John W. Mackay and others are interested, is in danger of interruption in consequence of a suit brought by order of the United States Attorney General. A bill of complaint was filed by United States District Attorney Wallace Macfarlane in the Federal Circuit Court in this city last week.

The suit is brought against La Compagnie Française des Cables Telegraphiques, the United States and Hayti Telegraph and Cable Company, and the United States and Hayti Cable Company. The complaint covers forty typewritten pages, and it alleges that the defendant companies are combining and conspiring together for the purpose of monopolizing a part of the trade and commerce between the United States and the several States thereof and foreign nations, to the irreparable injury of the people and business interests of this country.

An injunction is asked to prevent the defendants from carrying out their alleged unlawful agreement and from establishing their connecting cables on the shores of the United States. Part of the work of laying the cable between this country and Hayti, it appears, has already been accomplished. The American end of the cable starts from Coney Island. For the purpose, it is alleged, of laying a few miles of cable from Coney Island out to sea, where it could be connected with the West Indies and South American cable system, a corporation was formed, in February, 1895, entitled the United States and Hayti Cable Company. The charter was procured in West Virginia, and the stated capital is only $10,000. The incorporators named were John W. Mackay, George G. Ward, Albert Beck, John W. Mackay, Jr., and Albert B. Chandler.

Ten miles of cable were laid from Coney Island about July 9, 1895, and then the United States and Hayti Telegraph and Cable Company was organized under the laws of this State, the nominal capital being $1,800,000, and the incorporators Albert B. Chandler, Albert Beck, John Beattie, Edward C. Platt, John W. Mackay, and George Clapperton. The purpose of this company is believed to be to build a telegraph line

from New York City to Coney Island and to connect there with a cable to Hayti. Wires from this city extending through Connecticut, Rhode Island, Boston and other points on the coast of Massachusetts were provided for.

In the complaint filed last week the details of the alleged cable conspiracy are traced as follows: La Compagnie Française des Cables Telegraphiques is the successor in interest of companies heretofore known as La Compagnie Française du Telegraphe de Paris a New York, La Societe Française des Telegraphes Sousmarins, and of other French companies in the ownership of certain transatlantic cables between the United States and France, and of certain submarine cables in and between several islands of the West Indies, known as the Antilles, and of other lines of cable extending from these islands to several South American countries.

La Compagnie Française des Cables Telegraphiques owns a system of submarine cables starting from Santiago de Cuba and running thence to Hayti, San Domingo, Martinique and Guadeloupe, in the West Indies and thence to Dutch Guiana, French Guiana, and Brazil, in South America, and also a direct line from the Island of San Domingo to Venezuela. These cables have been laid, and are owned by La Compagnie Française des Cables Telegraphiques under concessions from the various countries, giving the company sole and exclusive right to land and to operate them between those countries and the United States for periods of from twenty-five to sixty years from the dates of concessions, which were granted between 1888 and 1890. By reason of these concessions no American countries or citizens are permitted to land lines of submarine cable in those countries.

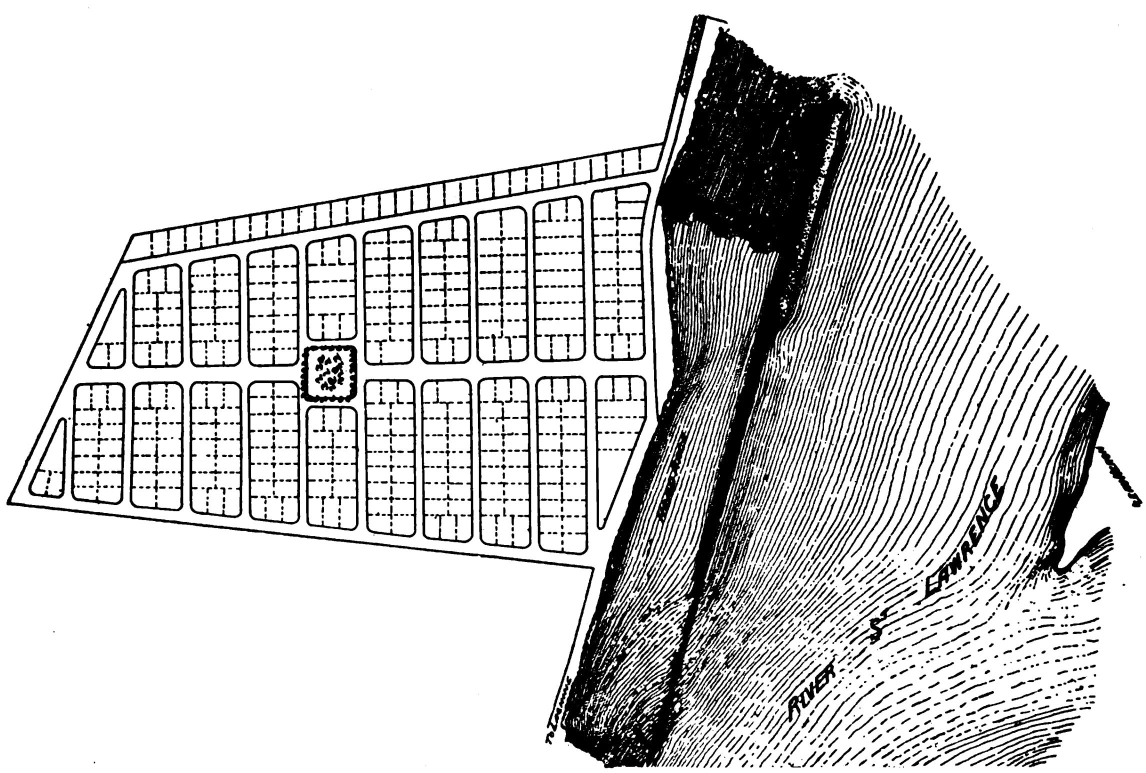
This French company is to receive for thirty years a subsidy of 800,000 francs per annum from France. For several years efforts have been made by this company and its predecessor to land a cable on the shores of the United States, but this Government refused to grant permission, except on condition that the French company surrender its monopoly between the United States and the islands and South American countries. For the purpose of evading this condition, it is charged in the bill of complaint, La Compagnie Française des Cables Telegraphiques entered into an unlawful agreement with the other defendant companies to secure direct communication between the United States and the West Indies and South American system of cables. The two American subordinate companies, it is asserted, were formed expressly for the purpose of enabling the French company to connect with our shores, and at the same time fulfill its special and monopolistic contract with the French Government.

It is further alleged that the French company had chartered two ships, one of which, the François Arago, has laid the shore end of the connecting cable off Hayti. The other vessel, the British steamer Seine, is now ready to make a connection with the Coney Island cable, and it is asked by the complainants that an injunction be speedily granted.

Power Transmission.

ELECTRICAL TRANSMISSION OF POWER FROM THE LACHINE RAPIDS TO MONTREAL.

The commencement of the second largest electrical plant in the world was successfully begun at Montreal, Canada, on Saturday, September 12. The harnessing of the Lachine Rapids of the great St. Lawrence River has been a work to which some of the first engineers of Canada have given their best days, but the great obstacles that nature has placed in the way, together with the lack of sufficient capital to carry out the immense project, have up to the present time proved insurmountable. As far back as 1867, a company known as the St. Louis Hydraulic Company was formed by the late James Key Springle, C. E., of Montreal, but the country was too young and not sufficiently advanced to admit of the accomplishing of the great work. At that time the English press remarked that the men who successfully carried out the scheme would be ranked among the greatest engineers of the age. When it is considered what immense power lay dormant in the St. Lawrence, it cannot be wondered at that several of the prominent capitalists of Canada, observant of what had been done in other water power plants, immediately came to the front with their financial backing, when the scheme was again prominently brought before the public in the summer of 1895. After the usual formalities had been gone through the needed permits had been received from the Canadian government, a meeting was called and on the 15th of July, 1895, the first subscription to stock was taken. At the present time $1,110,000 has been subscribed by twenty-two stockholders, of which $800,000 has already been paid in, the best evidence of faith both in the engineers and in the enterprise.



Electrical Power Development, Lachine Rapids, Montreal, Can.

The work, which might be called the making of an artificial canal, is situated on the north shore of the St. Lawrence, right upon the Lachine Rapids and about five miles from Montreal. The wing dam is constructed of crib-work filled in with boulders, with a cutstone ice fender at the upper end and triangular piers sunk at six feet below water to take up the fall that exists above the head-race. The greatest obstacle to overcome has been the action of anchor and "frazil" ice, the bugbear to all who have to do with water powers in Canada. The engineers have made a careful study of all of the surround-

ings since 1875, determining the bed of the rapids, the velocity of the water and the records of the state of the river. They have now, it is believed, adopted a course in constructing the dams and head-race which will be satisfactory and free from this trouble. Frazil ice is never known to form in still water or under ice; as the head-races will freeze over during the winter, no frazil will be formed in it. The dams and head-races have been formed so as to take advantage of the fact that the ice when it gets into still water will float to the surface, and consequently the power utilization will not suffer from it. Owing to the peculiar formation of the shore and the position of the dam in regard thereto the current tends to strike the dam at an angle and with great velocity, due to the rapids above. The water approaches the head-race at a very great velocity and continues thus over the overflow of the dam, carrying with it the floating anchor ice. A sort of water dam is formed at the intake, owing to the water moving into the head-race at a slow speed, creating no suction and carrying no anchor ice with it.

The main dam of the work running out from the shore consists of a series of isolated piers of masonry and concrete, and is constructed about 3,500 feet down stream from the ice fender. The piers are made to form the flumes to take the turbine wheels and shafting which generate and deliver the power. The sixty turbines will operate under a head of 12 feet and will develop 200 h. p. each, making a total of 12,000 h. p. all the year round. There are three power houses in which will be located the electrical generators, four in each power house, each of about 1,000 horse-power. These generators are coupled to a jack shaft, and six of the turbines are connected to this shaft with bevel cone gears, thus transmitting to each generator the power of six turbines, or 1,200 h. p. The building extends the full length of the main dam, and is 42 feet wide, excepting at the power houses, where it is 60 feet. The construction is of steel and each power house is to be equipped with a traveler which runs from end to end of the building. The original idea of the company was to generate the power merely and dispose of it on the jack shaft, and to lay out a large portion of the adjoining grounds into factory sites. During the winter, however, it was decided to bring the power into Montreal and dispose of it there. The capital was increased on this decision from $1,000,000 to $2,000,000, and a controlling interest was secured in the Citizens' Light and Power Company, which has valuable franchises, in order to receive an entrance into the city.

The contract for water wheels and hydraulic machinery is in the hands of the Stilwell-Bierce & Smith-Vaile Company of Dayton, Ohio, who have already delivered thirty-eight carloads of machinery. In order to distribute wires in the city underground, a contract for some 500,000 feet of cement-lined iron pipes has been awarded to the National Underground Conduit Company of New York, who are endeavoring to complete their work before the frost comes. The contractors for the main work are William Davis & Sons, of Ottawa.

The opinions of the most expert engineers in Canada have been obtained by the company and they, one and all, have indorsed the statements of the company's own engineers. By the first of the new year the entire work on the immense construction will have been concluded and the power brought into the company's house in Montreal, where already the chances of better and cheaper lighting and power are being looked forward to with very lively interest. In addition to the great development of water power, the Lachine Hydraulic and Land Company have decided to lay out their property adjoining the work in the form of a model town. The property will be divided into building lots, drained, graded, supplied with water, electric lighting and electric heating, besides having its own electric railway to Montreal. The engineers and promoters of this greatest enterprise of its kind in Canada are W. McLea Walbank and Thomas Pringle & Son, of Montreal, and to their ability and efforts is due the success of the undertaking, as far as it has gone.

CALIFORNIA MINES.—It is said by "Harper's Weekly" that electricity has made a great change in mining in California, where there are now 800 more mines at work than in 1895, the number now being 2,411, employing 18,410 men. Only a few years ago no ore which assayed less than $10 a ton could be worked with profit; now $4 ore may be made to pay if water power is near and abundant. "Electricity gives the greatest aid to the miner, for it permits him to carry power over mountain canyons, and to work mines which were formerly inaccessible."

H. M. LA FOLLETTE, an ex-Congressman, has been arrested on the charge of selling by fraudulent representation 122 bonds of the Connorsville Gas and Electric Light Company, a concern formely owned by J. N. Huston, treasurer of the United States.

PRESENT STATUS OF THE DISTRIBUTION AND TRANSMISSION OF ELECTRICAL ENERGY.[1]—I.

BY DR. LOUIS DUNCAN.

It is my purpose to take up the different methods of transmission and distribution and to consider the limits that are actually fixed by the present status of electrical development. The question is a commercial one, each problem presenting different conditions which must be considered, but certain general principles govern each case, and our knowledge and experience makes it possible to judge the practicability of each particular transmission.

GENERATING PLANTS.

At the present time practically all of the electrical energy distributed is generated in plants operated either by steam or water power, and it is important to consider the conditions of maximum economy in large generating plants, as this bears directly on the subject of transmission and distribution.

Some of the latest steam plants have machinery of the highest possible efficiency, and yet if we consider the price per horse-power of the power generated, we will find that it is greater than we expect. This is partly due to the fact that for both lighting and power purposes the load on the station, is, as a rule, not uniform and the apparatus is not working under the best conditions for economy. If we take the load diagram of such stations in large towns, we will find that the average output is not greater than 30 to 40 per cent. of the maximum output. We have, therefore, to supply a large amount of machinery corresponding to the maximum demand on the station, while for distribution a large amount of copper is required that is only being used at its maximum capacity for a comparatively short period of the time. In stations supplying power for traction purposes we find a variation of load, but the variation is a different kind from that found in a lighting station. In the latter the load varies at different hours in the day, but for any particular instant it is practically constant. In the former the average load for different hours during which the station is operated will be practically constant, but there will be momentary variations depending upon the size of the station and the type of traffic. Taking for instance a 2,000 horse-power station in Baltimore, I find that the average load is 48 per cent, of the momentary maximum load. This difference in the kind of variation for the two types of stations necessitates employment of different apparatus to obtain the maximum economy for each type. For lighting stations triple expansion engines may be used, while for traction work, where the variation in the load is sudden and may occur after the steam is cut off from the high pressure cylinder, it is not well in general to go beyond compound engines, and there is even a question as to whether simple engines are not more economical when condensing water cannot be obtained. In any case, however, it is of the utmost importance as regards economy of operation that the load should be made as constant as possible.

Two distinct types of distribution are used for incandescent lighting in this country—the single-phase alternating current and the direct current three-wire system. At the present time the former does not permit the supplying of power.

With the alternating system it seems impossible to provide even a moderately steady output, but with the continuous current system the motor load during the day gives an average output greater in proportion to the maximum. Some years ago the question of the relative values of the alternating and direct current systems was discussed, and for a while most of the stations installed were of the alternating type. At present the tendency seems rather in the direction of continuous current stations, especially in towns where there is a large demand for current within a comparatively small area. There is a great advantage of direct currents in that they allow the employment of storage batteries, which equalizes the load on the station. The efficiency of batteries in lighting stations is comparatively high, while the depreciation has been greatly reduced, and is not now over five or six per cent. per annum. In most systems, however, the full benefit of the storage batteries is not realized, as the batteries are placed in the station, and while the advantage of an approximately constant load is obtained, yet the further advantage offered in distribution is not secured. I will take this question up later.

As far as traction stations are concerned, their efficiency and output would be increased by the use of batteries, both because the machinery would be steadily loaded and because the most efficient type of apparatus could be used, as is the case in lighting stations.

If storage batteries are used the two types of variable load belonging to lighting and power stations demand different

[1] Presidential inaugural address read before the American Institute of Electrical Engineers, Sept. 23, 1896. Abstract.

types of battery. For lighting stations a considerable capacity is required,, while the momentary variations of power stations do not require any great capacity, but demand as great a maximum output as battery manufacturers can obtain.

In water power plants the conditions of economy are different. The location of the plant is, of course, definitely fixed, and the advisability of obtaining a uniform load, by means of batteries, depends upon the local conditions.

We may conclude that while the practice in large lighting and traction systems is to multiply stations near centres of consumption, yet the economy of a single large station makes it important to consider whether it is not possible to concentrate our power at some point where the expenses will be a minimum and distribute by some of the methods which have in the last few years proved successful and economical. It is important to make the station load steady, and this may be done for continuous current lighting and traction plants by means of storage batteries.

ELECTRICAL DISTRIBUTION.

I shall first consider the condition of affairs in a traction system in a large city, where a number of suburban lines are operated. If direct distribution is attempted from a single station, it will be found that when the distance exceeds five or six miles a large amount of copper must be employed to prevent both excessive loss and excessive variation of potential on the lines. On suburban lines it is the latter consideration that usually determines the amount of copper used, and this is especially true on lines where there is a considerable excursion traffic. Even in the city itself, the supplying of sections at distances three or four miles from the station may require so much copper that it would be less expensive to operate separate stations. Several methods other than the direct method may be employed to remedy these difficulties. For outlying lines where the traffic is mainly of the excursion order, being variable both during the day and for different seasons, boosters may be advantageously used. It is perhaps best from reasons of economy to run the boosting dynamos from motors. If the average station potential is 600 volts, and it is boosted 300 volts, then the copper for a given loss would be decreased in the ratio of 36 to 81. The booster system has the advantage of the direct system when the cost of the additional apparatus together with the increased loss on the line, capitalized, is less than the increased cost of the copper necessary to produce the same result by the direct system. Whether the balance is in favor of one or the other depends on the distance and the variation of the load, and it is indifferent whether the variation in the latter occurs often or not.

If any transforming device is employed to feed a distant section of the line it must be remembered that the capacity of the device must be great enough to look out for the maximum demand on this section. Suppose now that we wish to feed some suburban line where the load has considerable momentary fluctuations but where the traffic is moderately constant during the year. In this case the booster could be used with a storage battery at the end of its feeder, the battery supplying the line. The advantages of this combination are greater than with the simple booster and in many cases they will compensate for the interest and depreciation on the battery and the loss in it. If the arrangement is properly made, the load on the booster and line wire will be practically constant, thus decreasing the capacity of the booster to that required for the average load, while less copper will be required for a given loss. As to the latter point, suppose a given amount of power is to be distributed in 24 hours, say, 200 amperes at 600 volts; if the load is uniform, the loss will be proportional to $200^2 \times 24$ hours. If it is all distributed in 12 hours, the loss will be proportional to $400^2 \times 12$ hours, or twice as much. So in the case of the steady load the same power could be transmitted with the same loss with half the copper. It makes no difference whether the variation extends over 12 hours in 24 or it occurs every other minute, the result will be the same. It is apparent then that it is of the utmost importance to keep the line steadily loaded, as well as the station, and this points to the location of the battery near the points of consumption and not in the station. By this system—a booster with storage batteries—it is possible, assuming the same loss, to transmit power to a distance of ten miles with approximately the same amount of copper that would be required for a five-mile transmission on the direct system. It would increase the economical radius of distribution twice and the area of distribution four times. A single station could economically supply lines within distances up to ten or twelve miles. If it is desired to still further increase the radius of distribution, it is possible to do this by employing some of the alternating current methods that have come into use. I will discuss these methods later, but at this point I may remark that the use of stationary and rotary transformers permits the energy to be transmitted in the form of alternating currents, and to be changed again into continuous currents of any required voltage. These rotary transformers supplied by an alternating current which is transmitted from the station at a high voltage, may be used to feed the line directly or they may be used to supply storage batteries which are connected to the line. In the latter case we have the advantage of decreased size of apparatus, of steady load on the station, and of a minimum cost of copper on the line; which system it would be best to employ would depend upon the distances and the character of the line and load.

Of the systems that I have proposed for city and suburban distribution from a single station, three have been successfully employed, namely: the booster system; the booster system with batteries and rotary transformers operating directly on the line. When we consider the advantages of a single station and a steady load, it seems evident to me, that many of the large traction systems would do well to concentrate their stations into one and to use the booster system with batteries for their outlying lines, and if necessary use rotary transformers for lines beyond the limit of ordinary suburban work.

MISCELLANEOUS.

COUNTER E. M. F. IN INDUCTION MOTORS.

BY PROF. HENRY S. CARHART.

THE conception of a counter electromotive force in a direct current motor is an essential one, for this counter electromotive force is indispensable to the action of the motor. It may almost be said that the function of the armature is to generate counter electromotive force. Without it no power can be obtained from the motor; and the measure of the electrical energy, converted into mechanical work by the motor, is the product of the back electromotive force and the current flowing through the armature.

Now while counter electromotive force in an induction motor is quite a different thing from this reactive electromotive force in a direct current machine, it will still be a useful exercise to trace out the analogies between the two. Any mode of treating a new or unfamiliar piece of mechanism that brings out the similarities to what is already familiar, in so far helps to an understanding of the newer device.

Consider, first, the case of an induction motor with a rotating field. If Ω is the angular velocity of the rotating field and ω that of the rotor, then the current and the torque are both proportional to $\Omega - \omega$ the slip. It is evident that the induction in the rotor is precisely the same as if the field stood still and the rotor were turned backward with the angular speed equal to the slip. If the speed of the rotor is the same as that of the field, then there is no induction in the rotor coils; if the rotor speed exceeds that of the field, then the induction is again the same as with a slip of equal value, but opposite in sign, and the motor becomes a generator. If W is the watts applied to the rotor, w the useful watts, and T the torque, then we may write $W = T\,\Omega$. and $w = T\,\omega$. Hence the efficiency is $w/W = \Omega/\omega$. The efficiency equals the ratio of the two speeds.

Now in a direct current motor the efficiency measured electrically is the ratio between the counter and the applied electromotive forces. It will be observed that when there is no slip there is no induction in the rotor. This is exactly equivalent to saying that then the counter electromotive force generated by the rotation of the rotor is equal to the electromotive force generated by the rotation of the field. And, in any case, when the slip has a definite value, the induction in the armature is less than it would be if it stood still, by a quantity proportional to the speed of the armature. In other words, there is a virtual counter E. M. F. exactly equal to that which would be generated if the field stood still and the rotor turned forward with the speed, ω. The back E. M. F. may, therefore, be said to be proportional to the speed of the rotor, and the E. M. F. applied to the rotor is proportional to the speed of rotation of the field. Hence the electrical efficiency is the ratio of the back E. M. F. to the total applied E. M. F. as in the case of a direct current motor.

Again, consider the case of a monophase induction motor. If the field is uniform or symmetrical the motor is not self-starting. But if the resistance of the rotor bears a certain relation to the self-induction, then when the rotor is given a good start it will continue to increase its speed up toward synchronism and will exert a large torque. Evidently when the rotor is turning, the currents in it must be less than when it stands still, with the same current through the stator coils. If the rotor is driven up to synchronism, then no currents will be generated in it, and there will be no torque. If the speed be increased beyond synchronism, induction will again take

place and the machine acts as a generator. The back E. M. F. then becomes greater than the direct E. M. F. of the system. Evidently then the rotation of the rotor in an alternating field produces what may with propriety be called a counter electromotive force. This E. M. F. generated by the rotation of the short-circuited coils in the alternating field reduces the currents flowing as in the case of the rotary field motor.

In one important respect back E. M. F. in an induction motor differs from the counter E. M. F. of a direct current motor. Since the armature in the latter is in series with the external circuit, the back E. M. F. acts directly to reduce the flux of electricity in that circuit. But in the induction motor the stator coils are entirely distinct from the rotor coils. It is very easy to see, however, that any reduction of current in the rotor by a real or a virtual counter E. M. F., due to the rotation, operates to reduce the current in the stator coils as well. For an induction motor is only a transformer with the secondary so arranged as to be capable of rotation. Now a stationary transformer is self-regulating. On open secondary, the primary acts simply as a choking coil; but when the secondary is closed, the current flowing through it operates by means of the mutual induction between it and the primary, to increase the primary current. Conversely, a decrease in the secondary current causes a decrease in the primary. The same mutual reaction takes place between the rotor and the stator in an induction motor. When the rotor current is reduced by means of the back E. M. F., due to the rotation, the reduction in the mutual induction between it and the stator, causes the latter to act more like a choking coil, and the virtual current through the stator is also reduced. In the primary or stator coils the counter E. M. F. is strictly the E. M. F. of self-induction. The mutual induction resulting from the secondary currents reduces or offsets the E. M. F. of self-induction. Of course, the difference of phase must be taken into account, but the general action is as described.

It will be seen, therefore, that it is quite possible to draw some strong analogies between induction and direct current motors in respect to the counter electromotive forces generated by the rotation of the coils of the rotating member in a magnetic field.

ELECTRICITY IN NAVAL LIFE.—III.

BY LIEUT. B. A. FISKE, U. S. N.

TELEPHONES.

The telephone is gradually making its way against the speaking tube. The latter has the advantage of simplicity of principle, the telephone of distinctness. The speaking tube is less apt to get out of order; the telephone does better service when it is in order. The speaking tube is more difficult to lead through the devious labyrinth of the compartments and it occupies valuable space, and while the telephone is not difficult to keep in order, the connecting wires sometimes get disconnected. The telephone has not as yet had a fair chance on shipboard because it is comparatively recently that the long-distance "solid back" transmitter has been introduced. So far as the writer's experience goes, the persons who are not acquainted with this telephone prefer the speaking tube, while those persons who are acquainted with both prefer the telephone.

The principal disadvantage of the telephone for military use is one that it possesses in common with the speaking tube, that is, that it is a very inefficient instrument when used by a person under excitement. With both the speaking tube and the telephone clearness of articulation and a voice not too loud are necessary, if the message is to be quickly and unhesitatingly understood at the other end, and men under excitement are sure to speak loudly and not very distinctly. For the transmission of orders, therefore, and for signaling to the engine rooms, helm and guns, visual indicators are coming into use. Visual indicators possess, besides the advantage of distinctness, the additional advantage that they do not add to the noise on shipboard and are not affected by it, and that the message which they bear remains in evidence until it is replaced by another message, so that "the last order" can always be referred to by a glance of the eye.

The writer has been engaged for some years in perfecting a system of electric apparatus for use in ships and forts which has of late emerged from the experimental stage and seems to contain the possibility of considerable usefulness. Most of this apparatus is based on a central principle of construction which aimed to avoid the inherent difficulty of previous electrical apparatus when used in or near sea air. This difficulty was apparently a trivial but really an almost insuperable one; the sea air attacked and corroded the metallic contacts with which the apparatus was filled. In nearly, if not all, the electrical apparatus used for signaling, the mechanism consisted of a train of wheels which were moved by a pawl and ratchet; the pawl and ratchet being moved, in turn, by an electro-magnet which pulled the ratchet wheel down one tooth every time the current was made and broken. Even the simplest mechanism made on this plan contained many parts, most of them small, and the greatest care was needed to keep everything in order. The only safety lay in hermetically sealing the cases, and this was far from satisfactory and made the mechanism inaccessible. In endeavoring to find a way out of the difficulty, the writer conceived the idea of using only unbroken circuits, which were varied in strength by gradual variations and never by jumps, the variations being indicated by galvanometers and attained by the moving of a wiper over a continuous wire of high resistance. And, as any general discussion of the subject of electricity in naval life would be incomplete if it omitted to mention the labors of even the humblest worker in the field, the writer feels emboldened to introduce to the Institute certain efforts of his own which, with two exceptions that will be designated, have passed official tests in service and are now in use in some of the new ships and are to be installed in others. Beginning with the simplest he respectfully presents the Helm Indicator.

ALTERNATE CURRENT TRANSFORMERS.—VIII.

BY DR. J. A. FLEMING.

With regard to the high pressure cable, it is customary to use ordinary duplex concentric cable, and if the service is a 2,000 volt service, then after the cable has been laid in the ground it should be tested by a pressure of 4,000 volts placed between the inner and outer members for one hour, and a pressure of 2,000 volts between the outer member and the earth, and the cable should not be accepted unless it has passed this test. As it is always desirable to use concentric cables in connection with all modern transformer systems of distribution it is necessary to pay attention to some peculiar effects which are observed in connection with concentric cables when supplying transformers, and during the remainder of the lecture I propose to occupy your attention chiefly with practical points connected with these effects. They may be divided into four classes. There are, first, those which may be called the resistance effects, which are effects connected with the distribution of the current over the cross-section of the conductor employed for the transmission of the alternating current. Secondly, there are the capacity effects, which depend upon the fact that a concentric cable is a large condenser or Leyden jar. Thirdly, there are the resonance effects, which are due to the reaction of this capacity upon the alternators, or the primary transformers. Fourthly, there are effects which may be called the initial stage effects depending upon the capacity of the cable, and the inductance of the transformers supplied through it, both of which co-operate together to produce peculiar effects at the moment when the cable carrying the transformers is switched into connection either with another live cable or with an alternator. We shall consider each of these in turn. It will be necessary to preface a detailed discussion of these effects by some general remarks upon the nature of current flow in inductive circuits. Every electric circuit which has self-induction or inductance and capacity has a natural period of electric vibration—that is to say, if the electric charge in it is disturbed, and then left to itself, it oscillates backwards and forwards as water would do in a long tube having the ends closed by elastic caps. In such a case, if the water was disturbed and then left to itself, it would oscillate to and fro in virtue of the fact that the mass of water possesses inertia, and that the elastic caps on the ends of the pipe permit the water to be displaced. In other words, such a closed pipe has what may be called hydraulic inertia and permittance. In the same manner, a circuit which has self-induction possesses what may be called electric inertia or inductance, and a condenser which permits of electric displacement to be made through its dielectric or non-conductor has what is called capacity or permittance. If a condenser with a capacity, C, is being charged through a resistance, having a value represented by R, the product, C R, is called the time-constant of that system, and it represents the time in which the charged condenser, if left to itself, short-circuited by the resistance, R, would fall in potential to a certain fraction (very nearly two-thirds of its original potential); again, if L is the inductance of a conductor and R its resistance, then $\frac{L}{R}$ is called the time-constant of that circuit, and this is the time in which a current in that circuit would rise to about two-thirds of its full value if a constant electromotive force is put upon the ends

of the inductive resistance. The first product, C R, is called the electrostatic time-constant of the condenser and resistance, and the quotient, $\frac{L}{R}$ is called the electromagnetic time-constant of the inductive resistance. If, then, we join together in series a condenser having a capacity or permittance, C, and an inductive resistance having an inductance, L, and a resistance, R, it can be shown that the complete, free, periodic time of oscillation of a charge of electricity in that system is given by this expression:

$$t = 2\pi\sqrt{\frac{L}{R}\,CR}.$$

In other words, the complete periodic time is equal to 2 π times the geometric mean of the electrostatic and electromagnetic time-constants. It must be noted that this is the time of oscillation of the charge when left to itself, but it is, of course, perfectly possible to make what is called a forced oscillation, and that is what is done in every transformer system. These electrical quantities have their mechanical analogues. Suppose, for instance, we take a pliable lath with a weight on it, and fix it at one end, the pliability of the lath is the analogue of the capacity of the electrical system, the mass of the weight on the end is the mechanical analogue of the induction of the system. If, then, we displace the lath, or bend it, and leave it to itself, it vibrates to and fro with a natural period of its own, in virtue of the fact that the system has pliability or permittance,

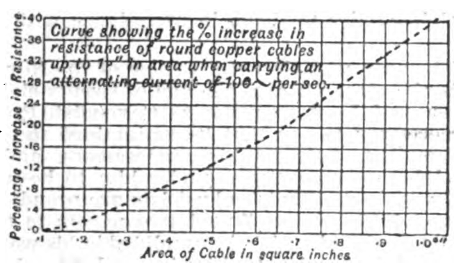


FIG. 48.

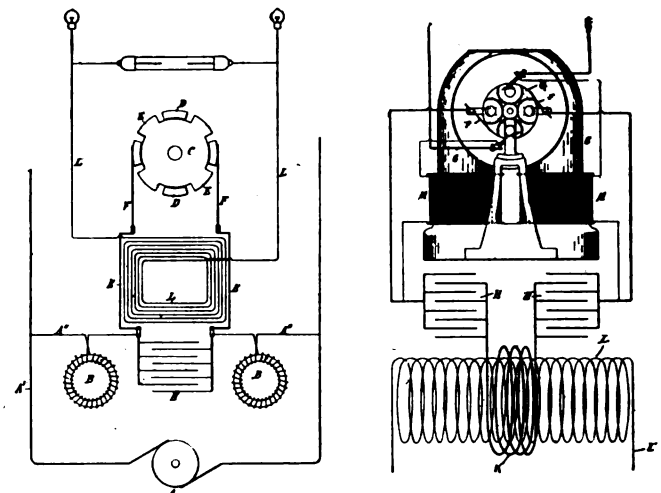
and mass or inductance. If the mass be small, and the pliability is small, the time of vibration is small; but if the pliability is great, and the mass is great, then the time of vibration is great. Such a loaded flexible rod not only has a free period of vibration of its own if fixed at one end and set in oscillation, but we may give it a forced oscillation. Before explaining the matter in which certain electrical effects may be mechanically imitated by such a loaded lath, we will consider a little more in detail the properties of concentric cables when used with alternating currents. In the first place, a cable intended for use with an alternating current must not have the metal or conductor of which it is made of a thickness exceeding a certain value, for the reason that a certain time has to elapse before the current is established in the central portions of the conductor, and, therefore, if the conductor is used with alternating currents, its actual resistance depends upon the frequency and the thickness of the conductor. Without going into more elaborate explanations on this point, for which I refer the reader to other text-books, I may give here a table showing the resistance of high conductivity round copper conductors to continuous and alternating currents of a certain frequency, the results of which are set out graphically in a curve in Fig. 48.

TESLA HIGH FREQUENCY APPARATUS OPERATED FROM LOW POTENTIAL DIRECT CURRENT CIRCUITS.

THE brilliant experiments in high frequency and high potential currents made by Mr. Tesla have been carried out by the aid of initial alternating currents raised from low to high potential. But in order to simplify the methods of work in this field, Mr. Tesla has devised a type of apparatus noted in our Patent Record last week, which enables currents of the desired high potential to be obtained from ordinary low potential continuous current circuits. In carrying out this scheme, Mr. Tesla employs a circuit breaker, around the contacts of which a condenser is connected, to store the energy of the discharge current; and in a local circuit and in series with the condenser he places the primary of a transformer, the secondary of which then becomes the source of the high frequency currents.

The accompanying diagram, Fig. 1, shows one form of the apparatus. The choking coils, B B, and circuit breaker, C, are placed in circuit with the continuous current mains, A. The circuit breaker is rotated by a continuous current motor. In parallel with the circuit breaker is the condenser, H, and in series with the latter the primary, K, of a transformer, the secondary, L, of which is the source of the high frequency currents.

Another, more convenient form of the apparatus is the arrangement shown in Fig. 2. In this case the motor, G, which



FIGS. 1 AND 2.—TESLA'S SIMPLIFIED HIGH FREQUENCY APPARATUS.

drives the circuit breaker, has its field coils in derivation to the main circuit, and the controller, C, and condenser, H, are in parallel in the field circuit between the two coils; the field coils, M, taking the place of the choking coils, B.

In this arrangement, and in fact generally, according to Mr. Tesla, it is better to use two condensers or a condenser in two parts and to arrange the primary of the transformer between them. The breaks of the field circuit should be so rapid as to permit only of partial demagnetization of the cores which should be laminated.

It will be apparent from a consideration of the conditions involved that were the condenser to be directly charged by the current from the source and then discharged into the working circuit a very large capacity would ordinarily be required, but by the above arrangement the current of high electromotive force which is induced at each break of the main circuit furnishes the proper current for charging the condenser, which may therefore be small and inexpensive. Moreover, it will be observed that since the self-induction of the circuit through which the condenser discharges, as well as the capacity of the condenser itself, may be given practically any de-

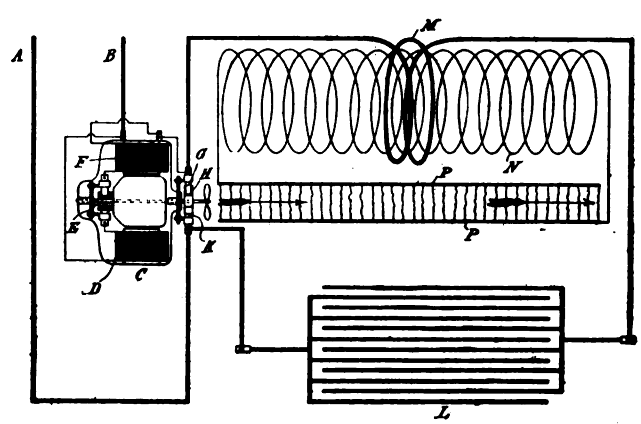


FIG. 3.—TESLA'S OZONE GENERATOR.

sired value, the frequency of the discharge-current may be adjusted at will.

Mr. Tesla has also devised a number of other methods for accomplishing the same object, which form the subject matter for a number of patents just issued to him.

Among the uses to which Mr. Tesla proposes to put the new arrangement is the generation of ozone in large quantities. The engraving, Fig. 3, shows the simple method employed for

this purpose. The high frequency brush discharge takes place between the metal plates, P P, and a current of air is forced between the latter by the fan blower attached to the motor that drives the circuit breaker.

PERSONAL.

PROF. J. J. THOMSON AND HIS WORK.

In view of the fact that Prof. J. J. Thomson, of England, will participate this month in the sesquicentennial exercises at Princeton and then deliver a special series of lectures on Electrical Discharges in Gases, renders of more than usual interest the accompanying biographical sketch, which we abstract from the London "Electrician," whose portrait of Prof. Thomson we also reproduce.

Prof. Thomson, the president of Section A, at the meeting of the British Association held at Liverpool, has advanced Physical Science in many directions, and especially in the direction in which the way was pointed out by Clerk Maxwell, his great predecessor in the Cavendish Chair of Physics at Cambridge.

Prof. Thomson was born at Manchester in 1856. Educated first at a private school, he entered Owens College at the age of fourteen. Thomson remained at Owens five years, and in his last year there he published his first paper; an experimental research showing that mere contact of two dissimilar bodies produces in them opposite electrifications, each of the

PROF. J. J. THOMSON.

same kind as that manifested when the two are rubbed together, and suggesting that the contact gives the polarization of which the friction enables us to take advantage.

On leaving Owens in 1876, Thomson entered Trinity College, Cambridge. In 1880 he graduated as Second Wrangler and obtained the Second Smith's Prize. In the same year he was elected a Fellow of his college, and later was appointed an assistant lecturer.

In Thomson's undergraduate years Maxwell still held the chair of Physics and his ideas and methods were now beginning to penetrate down to the undergraduate level, and to saturate the minds of all the more earnest students of Mathematical Physics. Naturally, then, we find that Thomson's first paper after his degree was inspired by his study of Maxwell's work. It was on the "Electromagnetic Theory of Light," and among other results he found that if light travels in a medium itself moving in the direction of propagation, the velocity is increased by half the velocity of the medium, a result already obtained experimentally by Fizeau in the case of water. Later, in his "Recent Researches," he returned to this point, and showed that the result obtained differs according to the preliminary assumptions made; and Prof. Lodge's experiments have sufficiently shown that the subject is still full of difficulties.

A year later, in 1881, this was followed by a paper investigating the motion of electrified particles in a magnetic field. He applied his results to the phenomena of a Crookes tube, assuming Crookes' explanation of a stream of charged atoms starting from the cathode, and he showed that the magnetic deflections observed by Crookes were of the kind given by his theory.

In the following years Thomson was occupied with a research on the value of "v," carried out in the Cavendish laboratory under Lord Rayleigh, and with investigations on vortex motion. These were published in the "Philosophical Transactions," and in 1883 he received the Adams Prize for an essay on Vortex Motion, a most important contribution to the subject. Applying the ideas of vortex motion to electrical theory, he began in 1883 his great work on the electrical discharge in gases by publishing a theory of that discharge on the supposition that a gas molecule consists of two vortex rings in a fluid strung on the same axis, and successively going through each other. The electric field he supposes to consist of some kind of distribution of velocity in the surrounding fluid. If the velocity is in one direction parallel to the common axis, the rings tend to separate, in which case he shows that there is a reduction of the velocity of the surrounding fluid; that is to say, the molecule tends to break up into separate atoms, and in so doing absorbs the electrical energy. The theory gives a reduction of pressure along the lines of force, and an increase at right angles to them, in accordance with Maxwell's theory.

In 1884 Thomson was elected a Fellow of the Royal Society, and later in the same year, at the age of twenty-eight, he was chosen to succeed Lord Rayleigh as Cavendish Professor. It is hardly necessary to say that he maintained the reputation conferred on that chair by his predecessors, and that the Cavendish laboratory continues under him to be a school of research of which all English physicists are proud.

In 1885 and 1887 he contributed two papers to the "Philosophical Transactions," which he amplified in his work on "The Applications of Dynamics to Physics and Chemistry," published in 1888. In the general methods of Lagrange and Hamilton any mechanical system is described not merely by distances, velocities and moments of the masses concerned, but by quantities analogous to these. Thomson applies their methods to a physical system in which the quantities describing the system are the ordinary quantities of physical measurement. By known results he obtains relations which must hold between these quantities, and then from the relations he obtains other results which may not hitherto be known. As an example, Ettinghausen and Nernst have found that if heat is flowing along a thin plate of an electric conductor placed in a magnetic field, there is an electromotive force perpendicular to the plane containing the lines of heat flow and the lines of magnetic force. This gives a relation which shows that if the effect holds also in a dielectric, then a heated dielectric placed in an electric field may produce a magnetic field. The work is a mine of suggestions for future research.

After the publication of Hertz's experiments Thomson made some notable contributions, theoretical and experimental, to the subject. Determining the resistance of various electrolytes, he showed it to be the same for the currents in Hertzian waves with a frequency of 10^8 as for steady currents. But if the electromagnetic theory of light is true, the electrolytes are perfect insulators for waves with a frequency of 10^{15}. Hence "the molecular processes which cause electrolytic conduction must occupy a time between 10^{-8} and 10^{-15} of a second." He also measured the specific inductive capacity of various dielectrics by making them in turn the insulator between the two plates of a Hertzian vibrator, and measuring in each case the length of the issuing waves. From this it is easy to compare the capacities. The values of K agreed with those required by the electromagnetic theory of light; and it is especially worthy of note that with a frequency of 25×10^6 the value of K for a glass plate was 2.7 or 1.65^2, practically the square of the refractive index for light waves; while for the same glass plate the tuning-fork method gave values between 9 and 11. "The discrepancy is probably due to the cause which produced the phenomenon of anomalous dispersion in some substances, and indicates the existence of molecular vibrations having a period slower than 25,000,000 per second."

Continuing the work on the discharge in gases, in 1890 Thomson showed that certain gases, when heated to the dissociation point, become good conductors, another link in the chain of evidence which he was gradually forming to show that the discharge is electrolytic, and that the dissociated atoms of a molecule are, the one positively, the other negatively charged. When the effect of heat is to break up the

molecule into atoms, the charges on the electrode may be regarded as neutralized by the charges on the dissociated atoms; or, rather, in the light of later theory, it may be said that the tubes of electric induction stretching from anode to cathode will more easily find chains of molecules on the point of dissociation through which they will pass, and whose dissociation they will complete. The tubes themselves will break up and discharge their energy in completing the dissociation. In his next paper, "On the Velocity of Propagation of Electric Disturbance," he makes full use of the idea of Grotthus' chains of molecules stretching through the gas, and shows that when such a chain becomes the seat of electric strain, it tends to break up, the atoms re-pairing, and leaving free a positively charged atom at one end and a negatively charged one at the other. He regards the striations as being groups of such chains, each striation being, as it were, a separate electrolytic cell with + atoms turned out at one end and — atoms turned out at the other. The spaces between are regions of combination of the — of one set of chains with the + of the next. We might expect such spaces to be proportional to the mean free path, for, as this increases, so also will the average distance traveled before re-pairing occurs. Observation gives fair confirmation of this. The increase of strength of a layer of gas with diminishing thickness finds an explanation, and he points out that if the distance between the electrodes in a tube is less than the distance between two striæ, then the recombination may not occur sufficiently rapidly, unless the velocity of the atoms is very much increased or extra energy is supplied. In other words, the resistance to the discharge is increased, and this is in accordance with experiment. The dark space at the end of the positive glow is, he supposes, a region where the heat of recombination has produced sufficient dissociation to render the gas easily conducting.

Now came a most important paper describing an experimental determination of the motion and velocity of the glow in an ordinary exhausted tube by the revolving mirror method. The glow was found to start always from the anode, and to move almost to the cathode with a speed nearly that of light. This speed far exceeds anything which could be atributed to the atoms themselves, for with such speed they would require immensely more energy than that supplied by the current. The traveling glow is therefore the propagation of a condition. The electric strain entering the tube passes down the Grotthus chains of molecules from the positive end, and with the speed of light, producing interchanges of patterns along the line.

All these views are set forth much more simply if the electric field and its changes are described by Faraday's induction tubes and their motion; and Thomson now turned to a development of the theory of these tubes, which will be found in his "Recent Researches."

His well-known experiments on the discharge in tubes without electrodes, and on the effect of a magnetic field in such tubes, still further confirmed his view of the nature of the discharge. Some experiments on the electrolysis of steam brought out the remarkable result that an arc discharge turns out the oxygen positively charged, so that it goes to the cathode while the hydrogen is negatively charged and goes to the anode. A spark discharge of a certain length exactly reverses these effects, and turns out the electrolytes at the ends at which they appear in the electrolysis of water. This experiment thus showed that the same atoms could have charges of either sign.

In 1894 the revolving mirror method was applied to measure the velocity of the cathode rays in a Crookes tube. The interval of time between the commencement of phosphorescence on two patches at different distances from the cathode on starting a discharge was measured in a hydrogen tube, and the velocity of the exciting agent was found to be 1.9×10^7 cm./sec., a hundred times greater than the velocity of mean square of hydrogen molecules at 0°C., but only a thousandth part of the velocity of the glow in a less exhausted tube. The velocity of the atoms on Crookes' theory of the rays may be calculated from the known fall of potential at the cathode, and the known charge carried by a known mass of dissociated hydrogen. Equating the electrical energy lost to the kinetic energy gained, Thomson found a velocity almost identical with that given by his experiments.

Combining this with his previous investigation on the magnetic action on electrified particles, it seems impossible to have any further doubt of Crookes' explanation that the so-called rays are a pure stream of electrified atoms. It is a misfortune that we still continue to describe the phenomenon thus, instead of terming it the cathode stream.

Last year further experiments were made to show that gases are electrolysed by the discharge, and the spectroscope was brought into the service. In one experiment a tube was divided in the middle by a metal plate perpendicular to its axis, and the spectra of the gases on the two sides of the plate could readily be compared. The same element was turned out from some compounds with a positive, and from others with a negative charge, and there was evidence tending to show that the spectrum given when the atom is positively electrified is different from that given by the same atom when negatively electrified.

Last December a very important paper was published in the "Philosophical Magazine," in which mechanical illustrations are given of the possibility of an atom being at one time positively and at another time negatively charged. It is shown that in one case it will possess more energy probably than in the other. The ideas derived from the illustrations are used to explain the difficulties in the theory of electrolysis.

I have given the fullest account of Prof. Thomson's researches on the electric discharge in gases, for they appear to me to constitute his greatest work. When he took up the subject there was an immense mass of confused and confusing facts. By his theory of Grotthus chains and their electrolysis, and by the series of test experiments, he has gone far to reduce the mass to order and to establish his theory.

We all know the part Thomson has taken in the work on the Röntgen rays, and have read his account of the subject in the Rede Lecture which he delivered a few weeks ago at Cambridge. Besides his contributions to Science in the form of papers and the works already mentioned, Prof. Thomson has edited "Maxwell's Electricity" and has added a third volume, "Recent Researches in Electricity and Magnetism," worthy of the work which it is intended to supplement. He has recently published a text-book on Electricity, which puts the mathematical theory of Electricity in a form useful to students who are unable to attack the difficulties of Maxwell.

Prof. Thomson's work has been recognized by the Royal Society in the award in 1894 of a Royal medal. He has been elected an honorary member of the Manchester Literary and Philosophical Society and of the Royal Society of Turin.

J. H. P.

MR. CHARLES J. LUTHER, late of the Long Branch, N. J., gas and electric lighting plant, has become superintendent of the Rome, N. Y., Gas Company, succeeding Mr. Parrish, and will operate both its services.

MR. T. F. GROVER, superintendent of the Milwaukee and Wauwatosa Electric Company, has been appointed general manager of the Fond du Lac, Wis., Electric Light and Power Company and will assume his new duties on October 1.

MR. PAUL MINNIS, heretofore General Manager of the Home Telephone Company, of Mobile, Ala., has accepted a position as electrical engineer with the Best Telephone Manufacturing Company, of Baltimore, and the allied Home Telephone Companies of Baltimore, Trenton, Newark, Jersey City, Cleveland and other cities. Mr. Minnis also has charge of the interests of his company for Greater New York with headquarters in this city.

MR. H. LOEWENHERZ, M. E., formerly in the Engineering Department, Metropolitan Telegraph & Telephone Company, of New York, is at present engaged upon extensive inside and outside work now being executed by the New York Telegraph and Telephone Construction Company for the Newark and Hudson Telephone Companies, operating in Newark and Jersey City, respectively.

PROF. HENRI MOISSAN is now making a tour through the Eastern and Middle States previous to proceeding to Princeton to represent the University of Paris at the College celebrations. Before he leaves at the end of the month, he will probably repeat his celebrated experiments with the electric furnace, in New York City, having consented to do so in response to an invitation from various societies. Arrangements are now being made.

MR. PERCIVAL ROBERT MOSES, formerly connected with the Sprague Electric Elevator Company, has now started as a consulting electrical engineer and contractor in the Equitable Building, 120 Broadway, New York, taking as specialties the installation of electric elevators and electric plants in buildings. Mr. Moses is a graduate of the electrical course of the Columbia College School of Mines. Since his graduation he has devoted himself entirely to the subject of electric elevators, and should be competent to deal with the problems they present.

TELEGRAPHERS' STRIKE ON THE CANADIAN PACIFIC.

The telegraphers on the Canadian Pacific Railway, including the train dispatchers, have gone out on strike, certain grievances being alleged. The report that the strike had interrupted traffic on the road is pronounced untrue by Mr. E. V. Skinner, General Eastern Agent of the company. Mr. Skinner said that the trains of the company were running regularly, passenger and freight, and that the places made vacant by the strikers were being filled without trouble.

SOCIETY AND CLUB NOTES.

NATIONAL SOCIETY OF ELECTRO-THERAPEUTISTS.

THE National Society of Electro-Therapeutists which held its annual convention on Sept. 29 and 30 last, proved to be a genuine success. The programme was composed of a large number of interesting and valuable papers, one of the most commendable and desirable features having been the frank admission of many failures in reaching the desired therapeutical result. But the many records of successful treatment by electricity gave this branch of medicine a most hopeful outlook. The president, Dr. A. B. Norton, reviewed in an interesting manner the development of the electro-therapeutist as a specialist, and then called on Dr. F. M. Frazer to read his paper on "The Treatment of Old Paralysis." Dr. Frazer explained how he applied the faradic current to a patient who had lost all control over the motions of his arm. Although the patient was not absolutely cured, the constant application of electricity had the effect of giving the party control over the movements of his arm and hand. In explanation, the author said that the nerve center must have been stimulated sufficiently to respond. The next papers were "A Few Cases Treated by Cataphoresis," by Emily A. Bruce, M. D.; "The Basis of Electro-Therapeutics," by Clara E. Gary, M. D.; "Some Failures and Cures in the Treatment of Endometritus," by F. A. Gardner, M. D., of Washington, D. C.

The evening session was of somewhat more direct interest to the engineer, since a number of engineering problems were brought out. A paper presented by Mr. Ralph W. Pope and Mr. Townsend Wolcott, on Alternating Currents and Transformers, caused a rather lively debate between the reader, Mr. Wolcott, and Lieutenant Jarvis Patten, Dr. Waite and Mr. Osterberg. The latter urged upon the physicians the use of the motor-dynamo in preference to using the current direct from the street, while Dr. Waite went so far as to call the proceeding of applying current directly from the street positively criminal. Lieut. Patten presented an interesting diagram from which he explained how a direct current may be turned into an alternating, and how this same device may be used to serve as a resistance. The principal idea involved in this scheme is to produce a positively uniformly varying alternating current. Dr. F. A. Gardner read a communication on "Some experiments with the Faradic current on a hypnotized subject." He personally experimented on a subject with the assistance of a professional hypnotist, and found most remarkable results. Nerves which under ordinary conditions would violently react were practically inert to the faradic current, when the subject was under the master's influence. The author also mentioned that a slight faradic current is often applied to a person while being hypnotized, but that person must not be aware of any such proceeding.

One of the most carefully prepared papers was that by the former president, Dr. William Harvey King, on the development of the higher vocal register by electricity. He explained how the vocal cord may be made elastic and how its muscular strength may be enlarged by the use of the faradic current.

William R. King, M. D., of Washington; Florence W. Oakey, M. D., of Brooklyn; Irving Townsend, M. D., and others presented papers of more direct interest to the physician than to the electrician. Next year's convention will be held in Washington, D. C., and Dr. F. A. Gardner was elected president for the ensuing year.

HENRY ELECTRICAL SOCIETY.

The first lecture of the season will be delivered at the rooms of the American Institute, Nos. 111-115 West Thirty-eighth street, New York, on Friday, October 9, at 8 p. m., by Mr. G. F. Sever, entitled, "The Development of Electric Railway Practice."

The society has decided to give public lectures every second Friday throughout the season, reserving the intervening Fridays for class work by the members only. This season the class, under the direction of Mr. W. H. Freedman, E. E., will study "Electric Lighting," as outlined in Prof. Crocker's new treatise on the subject which has been adopted as the text book to be followed.

The officers for the following year are: President, G. F. Sever; first vice-president, Nelson W. Perry; second vice-president, L. H. Laudy, Ph. D.; secretary, W. H. Freedman, E. E.

BASE AND SOCKET STANDARDIZATION.

For the greater convenience of several of the manufacturers who have signified a desire to be present, the date of the meeting for discussing the standardization of the incandescent lamp base and socket has been changed from Thursday, October 8, to the following day, when it will be held at 10 a. m. in the rooms of the American Institute of Electrical Engineers, Havemeyer Building, New York.

CHICAGO ELECTRICAL ASSOCIATION.

This association has got up a good programme of work for its coming winter season. The paper for Oct. 2 was on "Modern Views of Electricity," by Mr. F. J. Dommerque; and that on Oct. 16 will be by Mr. Albert Scheible on "Patents as Investments." Papers have been provided for up to Jan. 29.

NEW YORK ELECTRICAL SOCIETY.

The 176th meeting of this Society will be held at Columbia University, Oct. 13, at 8 p. m.

Dr. C. E. Emery will deliver his presidential inaugural address, entitled, "Reminiscences of Forty Years of Engineering Experience."

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION held a well attended meeting at Boston last week, when women physicians were particularly in evidence. Dr. Robert Newman, of New York, presided. Among the topics discussed were the dangers of using street current, a subject to which Mr. J. J. Carty, of New York, addressed himself. The programme has already appeared in these pages. Dr. W. T. Bishop was elected Dr. Newman's successor as president.

LETTERS TO THE EDITOR.

RATED AND ACTUAL HORSE POWER OF ELECTRIC MOTOR AND GAS ENGINE.

In the article on the Morris & Salmon Electric Carriage in The Electrical Engineer for Sept. 30, 1896, there are some statements that are a little misleading.

It is well known that an electric motor can, for a short time, generate about three times its rated horse power. Under the conditions of the Providence race, 8 or 9 horse-power would be a much fairer rating of the power which propelled the Morris & Salom wagon.

It is also suggested that the gasoline motors of 5 brake horse-power could be made to double their power. This seems a little odd. The experience of the writer has tended to the fact, that the rated brake horse-power of a gas or gasoline engine is very nearly its practical working limit, as those familiar with this class of engine know that when overloaded they stop.

Further, the motor carriage builders are working to make their wagons as light as possible, and under the circumstances they would not be likely to carry the extra weight of a 10 horse-power motor to generate only 5 horse-power.

S. A. HASBROUCK, M. E.

New York City, September 30, 1896.

X-RAYS IN A DRY GOODS STORE.

To add to the many attractions of their large establishment, Bloomingdale Bros. have recently opend an X-ray exhibition. A few words as to the details of this apparatus may be of interest. In many respects the apparatus is what may be called standard; but there are a few details that may be new. The coil is an 8-inch Splitdorf with the make and break circuit mounted on the shaft of a motor, the spark at the break being absorbed by condensers. The tube is of the focusing type and is made by Greiner, of this city. These tubes I wish to recommend very highly, as they are, by far, the most satisfactory of any I have ever seen. By proper manipulation I am able to make a very clear photograph of the hand with twenty to thirty seconds exposure, and a picture of the ribs in about ten to fifteen minutes. To operate the tubes to the best advantage, they are enclosed in a box and a gas flame placed inside with the tube; the flame serves for heating the tube as well as keeping the air dry. By this means I have sometimes operated a tube for two hours without shutting it down. A very essential thing in running tubes to their maximum effect is to keep the air around them dry. All who are interested in the X-ray should call at Bloomingdale's and see the apparatus in operation.

H. D. HAWKS.

New York City, Sept. 14, '96.

CLEVELAND, O. The Institute for Home Study of Engineering, Blackstone Building, owned and operated by the Scientific Machinist Company, has just issued a new and interesting catalogue in relation to its well known educational work. We learn that the institute's thorough and practical work in the different branches of electricity, mechanics, mechanical drawing and steam engineering, is proving very attractive to progressive and ambitious mechanical men.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Alternating Currents:

ON THE DISTRIBUTION OF HIGH FREQUENCY ALTERNATING CURRENTS THROUGHOUT THE CROSS-SECTION OF A WIRE.—By Ernest Merritt. Author exhibited by plotted curves, the results of extensive calculations from the formulæ of Lord Kelvin and Heaviside.—Note in "Science," Sept. 11, '96.

GRAPHICAL TREATMENT OF ALTERNATING CURRENTS IN BRANCHING CIRCUITS.—By Henry T. Eddy. Author gave an elegant treatment of the general problem of branched circuits containing resistance, inductance and capacity, showing the construction of the locus of the resultant current vector for varying frequency.—Note in "Science," Sept. 11, '96.

Central Stations:

CENTRAL STATION EXTENSIONS.—By G. L. Addenbrooke. Author defends an attack on his previous statement that under ordinary circumstances mains may be extended 2½ miles from the station using a three-wire system and 220 volt lamps.—Lond. "Elec. Rev.," Aug. 28, '96.

Dynamos and Motors:

COMBINED ALTERNATING AND CONTINUOUS DYNAMO AT WOOLWICH.—By F. J. Moffet, B. A. The object which the designers of this machine had in view, was to obtain in the case of an alternating current dynamo the same elasticity of output, which is possessed by a direct current machine when running in parallel with a set of storage cells.—Description of machine and diagram of connections of compound switch in Lond. "Elec.," Aug. 28, '96.

ARMATURE WINDINGS AND CONNECTIONS.—By Cecil P. Poole. Previously referred to; see for reprint "Scient. Mach.," Sept., '96.

NON-SYNCHRONOUS TWO-PHASE ALTERNATING CURRENT MOTOR.—See Syn., Sept. 23; also 'Elec. World," Sept. 12, '96.

Educational;

THE ARTISTIC ELEMENT IN ENGINEERING.—By Frank O. Marvin. Paper read before the Section D of the Buffalo meeting of the Am. Assoc. for the Advancement of Science. Author treats American engineering right through its gradual development and shows the development of æsthetics.—"Science," Sept. 11, '96.

THE WORK OF THE REICHSANSTALT.—A report of the work accomplished during the past year.—Lond. "Elec.," Aug. 28, '96.

Electro-Chemistry:

ELECTROLYSIS AND SOME OUTSTANDING PROBLEMS IN MOLECULAR DYNAMICS.—By Carl Leo Mees. Read before the Am. Assoc. for the Advancement of Science.

A THEORY OF GALVANIC POLARIZATION.—By W. S. Franklin and L. B. Spinney. Existence of a term in the energy equation of the electrolytic cell is pointed out, depending upon an irreversible or sweeping process at each electrode. Experiments were described showing that the coefficients of these terms do not in general vanish with the current.—"Science," Sept. 11, '96.

ON IRREVERSIBLE CELLS.—By A. E. Taylor. This paper is practically a continuation of the work of Bancroft on single liquid polarizable cells, with special reference to the effect of the negative ion on the potential difference between an electrode and the electrolyte in which it is immersed.—"Journ. of Physical Chemistry," Oct., '96.

Electro-Physics:

MECHANICAL MODELS OF THE CIRCUIT.—By Brown Ayres. A model was constructed showing nearly all the fundamental phenomena of the electric circuit, particularly those of oscillation and resonance.—Note from "Science," Sept. 11, '96.

VISIBLE ELECTRIC WAVES.—By B. E. Moore. Author describes an arrangement in which stationary electric waves on a wire are rendered visible by the brush discharge from the various points of the wire.—Note in "Science," Sept. 11, '96.

ELECTRIC WAVES IN LONG PARALLEL WIRES.—By A. D. Cole. Author has carried out some work in connection with the determination of the dielectric constants of liquids.—Note in "Science," Sept. 11, '96.

INFLUENCE OF THE STATIC CHARGE OF ELECTRICITY ON THE SURFACE TENSION OF WATER.—By E. L. Nichols and John Anson Clark. Authors used a dropping apparatus for determining the surface tension, and a novel electrometer for measuring e. m. f. The electrometer consisted of a light conducting sphere suspended by a long conducting fiber near a large plane plate.—Note in "Science," Sept. 11, '96.

Lighting:

ON THE COUNTER E. M. F. OF THE ELECTRIC ARC. —By W. S. Franklin. Author attempted the experimental determination of the decay of the e. m. f. between the carbons of the electric arc after the circuit is broken.—Note in "Science," Sept. 11, '96.

Measurements:

A NEW ALTERNATING CURRENT CURVE TRACER.—By Edward B. Rosa. An apparatus by means of which the successive points in an alternate current or e. m. f. curve are plotted directly, avoiding the necessity of taking and entering numerical observations.—Note in "Science," Sept. 11, '96.

Mechanical:

WESTINGHOUSE GAS ENGINE.—A brief description of the new gas engines adapted for dynamo driving.—"R'way Review," Sept. 26, '96.

Power Transmission:

NEVADA COUNTY (CAL.) ELECTRIC POWER COMPANY.—A Head of 206 feet is attained on the River, and the water is carried to Pelton Wheels through 300 feet of 48 inch, 44 inch and 42 inch pipes, giving in all 2,500 h. p. Two 340 k. w. two-phase 5,000 volt generators running at 400 revolutions are installed; also two 5 k. w. exciters.—For detailed description see "Elec. Eng'r." Sept, 16, '96.

Railways:

COMBINED CONDUIT AND OVERHEAD SYSTEM.—This trolley tramway system has been developed in Washington. Besides a brief description, the illustrations help to explain the system.—"R'way World," Sept., '96.

WORKING EXPENSES OF ELECTRIC AND CABLE RAILWAYS.—Only one cable road is mentioned and that is compared with the Liverpool Electric and London electric systems.—"R'way World," Sept., '96.

Roentgen Rays:

NOTE ON THE DURATION OF THE X-RAY DISCHARGE IN CROOKES TUBES.—By Benjamin F. Thomas. Slow make and break in the primary of an induction coil produces almost as strong effect on a Crookes tube as very rapid make and break. This seems to indicate the long duration of activity of the tube at each discharge. Author has shown that the duration of the acting discharge is as short as 1/5000 and probably as short as 1/50000 second.—Note from "Science," Sept. 11, '96.

ROENTGEN RAYS IN OPHTHALMIC SURGERY.—Dr. Lewkowitsch has devised a method for detecting foreign bodies in the eye.—From Lond. "Lancet," in "Elec. Rev.," Sept. 2, '96.

Telegraphy:

ENGLISH POSTAL TELEGRAPH SERVICE.—From the annual report of the Postmaster General, the following table is abstracted:

Class of Telegrams.	Number. Year, '95-'96.	Receipts.
Ordinary Inland	64,563,587	£2,046,456
Press Inland	5,915,646	124,881
Foreign	6,701,838	331,717
Railway, free	1,338,818	......
Railway, half rate	24,350	469
Government, free	295,371	......

—Lond. "Elec.," Aug. 28, '96.

ARRANGEMENT FOR COUNTING CONVERSATIONS OF TELEPHONE SUBSCRIBERS.—By Jul. H. West.—From "Elektrotechn. Zeitschr." in "Elec. World," Sept. 12, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED SEPT. 29, 1896.

Alarms and Signals:—

SIGNAL BOX. C. W. Cornell, East Orange, N. J., 568,335. Filed Dec. 5, 1895.
Means for permitting the operation from a distance of a normally unwound signal box.

ELECTRIC ALARM FOR STEAM GAUGES. A. Ransom and A. J. Corrothers, Wise, W. Va., 568,370. Filed Jan. 25, 1896.
Details of construction.

SIGNALING BY MEANS OF LIGHTS. L. Sellner, Vienna, Austria-Hungary, 568,374. Filed Nov. 19, 1895.
Comprises a signaling element composed of two normally obscured signal lights of unlike color, and adapted to alternately expose the lights to view.

ANNUNCIATOR. C. E. Beach, Binghamton, N. Y., 568,423. Filed Aug. 16, 1895.
Comprises a magnet, an armature mounted on a revoluble part to rotate therewith and having an independent vibratory motion in the direction of the magnet, together with a ledge for holding the armature.

ANNUNCIATOR TIME CALLER FOR RAILROAD TRAINS. J. J. Cowhig, Manassas, Va., 568,430. Filed Feb. 25, 1896.
Consists of a board having a clock face and hands, lettered sliding paddles, a drop board and an alarm bell, the latter two operated by electricity and a switch.

ELECTRIC WEATHER INDICATOR. W. M. Kelch, Dayton, O., 568,444. Filed Nov. 21, 1894.
Comprises mechanism for simultaneously indicating at different localities, from a single point, information appertaining to the weather.

AUTOMATICALLY TESTING FIRE ALARM CIRCUITS. L. G. Rowand, Camden, N. J., 568,493. Filed Aug. 2, 1895.
Employs a local battery, the various circuits, etc., being automatically by clock mechanism switched into circuit with the local battery.

ELECTRIC FIRE ALARM CIRCUIT AND SIGNAL BOX. L. G. Rowand, Camden, N. J., 568,494. Filed Aug. 8, 1895.
Details of construction.

FIRE ALARM CIRCUIT. L. G. Rowand, Camden, N. J., 568,495. Filed Aug. 13, 1895.
Details of construction.

ELECTRIC SIGNALING APPARATUS. A. Garing, Carlstadt, N. J., 568,606. Filed April 21, 1896.
Adapted for use on trolley roads.

ELECTRIC BELL. F. Davey, Detroit, Mich., 568,668. Filed Feb. 17, 1896.
A single stroke bell.

Batteries, Secondary:—

SECONDARY BATTERY. F. King, London, England, 568,447. Filed April 10, 1896.
Means to effect circulation of the electrolyte over the surfaces of the plates.

Dynamos and Motors:—

ALTERNATING CURRENT ELECTRIC MOTOR. F. S. Hunting, Fort Wayne, Ind., 568,350. Filed Aug. 31, 1892.
Comprises a closed secondary circuit and means for varying the phases of the electromotive forces developed in its different parts.

BRUSH HOLDER. S. H. Short, Cleveland, O., 568,413. Filed Oct. 29, 1895.
Comprises an adjustably mounted brush-supporting board of suitable non-conducting material arranged between the brush and the end of he motor armature.

ARMATURE WINDING. S. H. Short, Cleveland, O., 568,414. Filed April 20, 1896.
An armature coil having side and end portions, the side portions provided with paper insulation, and the end portions provided with tape insulation.

FLAT WINDING FOR ARMATURES. S. H. Short, Cleveland, O., 568,415. Filed May 4, 1896.
Details of winding.

CONSTANT POTENTIAL ALTERNATING GENERATOR. C. P. Steinmetz, Schenectady, N. Y., 568,464. Filed April 30, 1894.
The combination of an alternator, an exciter, a regulating machine in the exciter circuit, and a field coil on the regulating machine energized by the rectified current of the alternator.

CONSTRUCTION AND OPERATION OF CIRCUITS FOR ELECTRIC MOTORS. F. E. Herdman, Winnetka, Ill., 568,566. Filed June 21, 1895.
Adapted for use with electric motors operating elevators.

ALARM DEVICE FOR ELECTRIC MOTORS. W. A. Gibbs, Pawtucket, R. I., 568,608. Filed Dec. 14, 1895.
Indicates when the armature touches a pole piece of stationary magnet of the motor.

Electro-Metallurgy:—

PROCESS OF PICKLING METALS. A. S. Ramage, Chicago, Ill., 568,412. Filed April 9, 1894.
Consists in a neutral solution of the salt of the metal to be pickled, such solution being acidified, and passing a current of electricity from the article to be pickled through the solution.

Lamps and Appurtenances:—

MEANS FOR ATTACHING OR DETACHING ELECTRIC LIGHT GLOBES. F. W. Mayer, Hartford, Conn., 568,408. Filed June 26, 1896.
Comprises a pair of bands adapted frictionally to engage a lamp-globe at different points in its length.

BRACKET FOR ATTACHING INCANDESCENT LIGHTS TO COMPOUND GAS FIXTURES. E. C. Howe, Bridgeport, Conn., 568,573. Filed July 20, 1896.
Comprises an adjustable bracket which will permit the light to be swung into any desired position.

ELECTRIC ARC LAMP. W. Jandus, Cleveland, O., 568,721. Filed March 5, 1896.
Inclosed carbon type.

Miscellaneous:—

MANUFACTURE OF GRAPHITE. E. G. Acheson, Monongahela City, Pa., 568,323. Filed Dec. 27, 1895.
Consists in subjecting a carbid to the action of an electric current and thereby decomposing it and causing the combined carbon to separate in the form of graphite.

ELECTRIC THERMOSTAT. J. E. Meek, New York, 568,451. Filed May 20, 1896.
Adapted for use in electric heaters.

EXTINGUISHING ELECTRIC ARCS. W. B. Potter, Schenectady, N. Y., 568,450. Filed June 20, 1896.
Consists in causing the lines of force of an arc rupturing means to localize the arc at approximately a given point of the contacts, and then to rupture it.

SYNCHRONIZING DEVICE FOR ELECTRIC CLOCKS. W. J. Cruyt, Brussels, Belgium, 568,475. Filed Jan. 7, 1895.
Details of construction.

ELEVATOR MECHANISM. H. R. Wellman, North Tonawanda, N. Y., 568,506. Filed Jan. 13, 1896.
Means for converting the rotation of a driving shaft into a rectilinear motion of a cross-head and to provide a means for operating this shaft by means of two motors.

ELECTRIC ELEVATOR. F. E. Herdman, Winnetka, Ill., 568,567. Filed Oct. 5, 1895.
Means to enable the elevator to be driven from the motor shaft without form or gear.

ELEVATOR MOTOR CONTROLLING DEVICE. F. E. Herdman, Winnetka, Ill., 568,568. Filed Oct. 5, 1895.
Means whereby the strength of the field in the motor at predetermined points in the travel of the elevator is automatically increased.

BRAKE MECHANISM FOR ELECTRIC ELEVATORS. F. E. Herdman, Winnetka, Ill., 568,569. Filed Oct. 5, 1895.
Means so that the brake shall not be removed until sufficient power is on the machine to enable it to move the load in the direction required.

BRAKE MECHANISM FOR ELECTRIC ELEVATORS. F. E. Herdman, Winnetka, Ill., 568,570. Filed Oct. 5, 1895.
Means to make the application of the brake vary as the conditions of speed and load vary.

BRAKE MECHANISM FOR ELECTRIC ELEVATORS. F. E. Herdman, Winnetka, Ill., 568,571. Filed Oct. 5, 1895.
Similar to above.

INSULATING COMPOUND. L. Honig, St. Louis, Mo., 568,683. Filed June 24, 1896.
Consists of alcohol, shellac, powdered asbestos, glycerin, glue and wheat flour.

ROENTGEN RAY EXHIBITION APPARATUS. A. A. Hamerschlag, New York, 568,720. Filed May 20, 1896.
The combination of a casing, one or more fluorescent tubes therein, heads adjustably supported upon the casing, and one or more fluoroscopes or eyepieces hinged to said heads.

Railways and Appliances:—

RAIL BOND. F. H. Underwood, Auburndale, and F. H. Daniels, Worcester, Mass., 568,385. Filed April 7, 1896.
Embodies a terminal made separate from the conductor and provided with a hole for the conductor and a hole for a drift pin.

TROLLEY WIRE SUPPORT. W. A. McCallum, Cincinnati, O., 568,452. Filed March 2, 1896.
The action of the wire itself retains it immovably in position.

TROLLEY SYSTEM FOR ELECTRIC RAILWAYS. C. E. Davis, Chicago, Ill., 568,523. Filed April 27, 1896.
Designed for use in mines.

SIGNALING SYSTEM FOR RAILWAYS. F. C. Timpson and R. F. Rankin, Philadelphia, Pa., 568,644. Filed Dec. 14, 1895.
Comprises a line circuit, a magneto-machine having a tubular shaft, an electromagnetic signaling device and a rod mounted in the shaft and adapted to extend into range of a key and to reset the signaling device.

ELECTRIC TRACK CIRCUIT RAIL JOINT. G. H. Williams, Fort Smith, Kan., 568,650. Filed March 18, 1896.
A fish plate or angle bar having a longitudinal conductor receiving groove extending from end to end along its upper edge.

ELECTROMAGNETIC ADHESIVE DEVICE. A. A. Honey, Tacoma, Wash., 568,682. Filed Jan. 25, 1896.
Means for increasing the tractile power between wheels and rails.

RAIL BOND FOR ELECTRIC RAILWAYS. C. C. Benson, Covington, Ky., 568,713. Filed Dec. 1, 1894.
Consists in a bond having a connecting wire and split collar, the latter adapted to be driven into the aperture of the web.

Regulation:—

TANDEM PARALLEL CONTROLLER FOR INDUCTION MOTORS. W. B. Potter and F. E. Case, Schenectady, N. Y., 568,458. Filed Aug. 31, 1895.
Comprises contacts and cross-connections adapted to connect the motors in tandem or parallel at will, and cut-out switches arranged to cut out part of the motors without affecting the operation of the remainder.

Switches, Cut-Outs, Etc:—

ELECTRIC SWITCH. J. E. Meek, New York, 568,450. Filed March 20, 1896.
Embodies a swinging knife blade to which the supply current is delivered, and a rotating table having its axis non-coincident with the pivotal point of the swinging knife blade.

Telegraphs:—

PERFORATOR. C. L. Buckingham, New York; E. Germann and J. W. A. Gardam, Brooklyn, N. Y., 568,512. Filed Aug. 13, 1895.
Designed to perforate material for use in telegraph transmitters.

TELEGRAPH RECEIVER. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 568,513. Filed May 11, 1896.
Comprises step-by-step feed, a manual controller, a catch and means operatively connected therewith for actuating the catch by the power applied to move the controller.

PERFORATOR AND CIRCUIT CONTROLLING APPARATUS THEREFOR. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 568,514. Filed May 11, 1896.
The combination with a series of controlling keys, of a system of yielding chains transverse thereto and punch controlling devices connected to the chains.

PERFORATING MACHINE. C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 568,515. Filed May 11, 1896.
Comprises a punch wheel having radially projecting punches, and a series of co-operating dies formed as a flexible band.

PERFORATOR. C. L. Buckingham, New York; J. Gardam and E. Germann, Brooklyn, N. Y., 568,516. Filed May 11, 1896.
Comprises a series of punch actuating magnets, a series of circuit selecting keys for operating the punches, a paper feed, and a series

of feed controlling magnets different ones of which are brought into action by the keys according to the extent of feed required.

TELEGRAPH SOUNDER. D. M. Dunn, Abingdon, Va., 568,527. Filed Jan. 27, 1896.

A combined relay and sounder, comprising a relay-magnet having attached to its armature a buckled plate held fixedly at one end and adapted to have its plane shifted with a click by the movement of the relay armature.

TELEGRAPHY. R. Greville-Williams, Heywood, England, 568,675. Filed Oct. 5, 1895.

Apparatus for the fac-simile reproduction at a distance of designs, drawings, manuscript, etc.

Telephones:—

TELEPHONE MECHANISM. J. L. Given, Stony Point, N. Y., 568,346. Filed Dec. 6, 1894.

Means for separately registering the use of a telephone by more than one subscriber.

SUBSTANCE FOR TELEPHONE ELECTRODES. D. Drawbaugh, Eberly's Mill, Pa., 568,526. Filed Jan. 10, 1896.

Comprises platinum-black in an agglomerate mass divided into granules.

AUTOMATIC SWITCH ARM FOR TELEPHONE RECEIVERS. H. Marcuse, Berlin, Germany, 568,577. Filed Jan. 7, 1896.

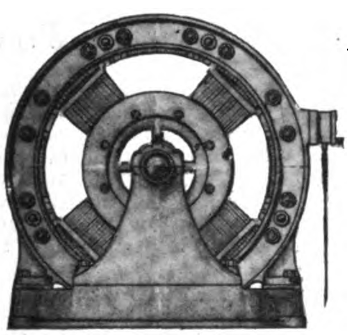
Means to avoid manipulating the receiver by hand.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

C & C INDUCTOR ALTERNATOR.

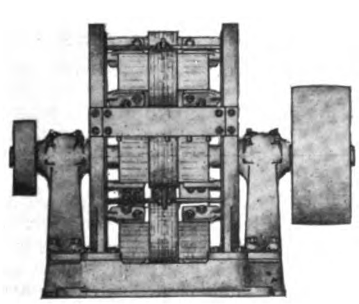
THE C & C Electric Company, so long and favorably known as manufacturers of continuous current dynamos and motors, are about to launch into a new field; and if prospects count for anything, the C & C inductor alternator will soon be as well established on the market as is now the case with C & C motors. The tendency of the age is to simplify electrical machinery, and as far as possible avoid the necessity for



NEW C & C ALTERNATING CURRENT GENERATOR.

using commutator or collector. In the new C & C alternators (inductor type) simplification seems to be a predominating feature, while at the same time no pains have been spared to make these alternators, not only of high efficiency, but of great durability.

Among the details most perfectly worked out in the machine is pre-eminently the fact that all windings may be removed and replaced, even by a novice, in a very short period of time.



NEW C & C ALTERNATING CURRENT GENERATOR.

The magnetic circuit is most carefully constructed of laminæ of soft charcoal iron, and all tendencies to iron losses are most carefully guarded against.

The rotor, or rotating part, is a simple piece of steel in which the magnetic flux has a constant value, excepting for the projecting lugs, which are built of laminæ of soft charcoal iron, in which there is but small change of the magnetic flux.

The machines illustrated in the accompanying engravings are wound for any voltage, namely, 125, 250, 500, 1,000, 2,000, 5,000, 10,000, and the insulation is such that at any of these voltages a perfect performance is realized. The speeds are low in all cases, being but 900 revolutions per minute in the smallest size. The frequency is established at sixty periods per second as a standard, but machines of any frequency will be furnished on demand.

The C & C Electric Company propose to construct regular sizes as follows:

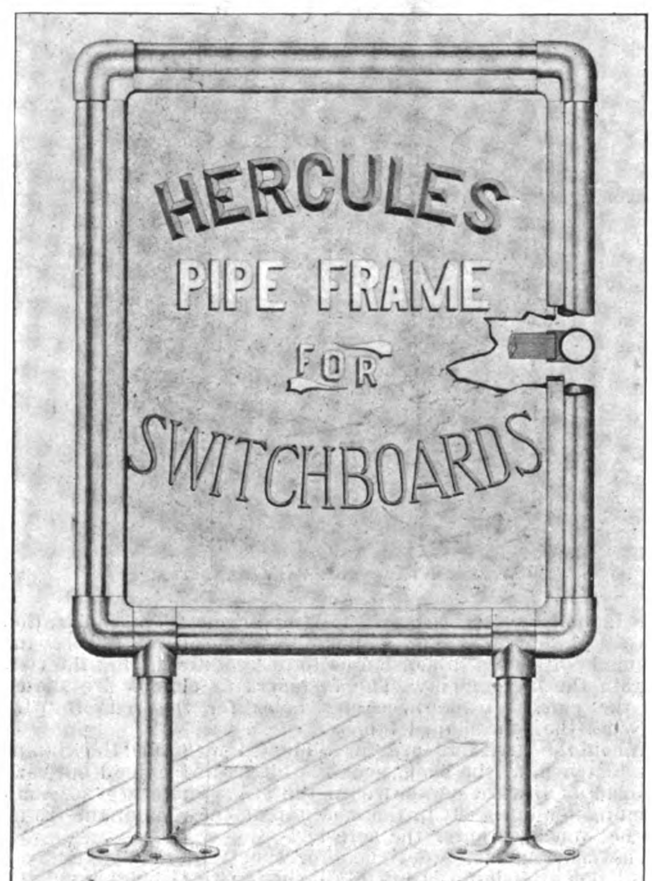
K. W.	Speed.
25	900
50	720
100	600
200	450
400	360

Transformers will be furnished in all regular sizes, and the switchboard equipment will be most perfect and complete.

The C & C Company anticipate a good demand for their new equipment, and, we are informed by Mr. T. J. Fay, general manager of the company, that already there are many prospective sales in sight, notwithstanding the fact the political situation makes business in general hard to get.

A PIPE SWITCHBOARD FRAME.

THE accompanying sketch illustrates an unique style of tubular frame for mounting switchboards. As the cross section shows, its parts are, the tubular frame, screwed into fittings to make corners or to secure outlets for stanchions, braces, etc., and special channel pieces which receive the marble, or slate board proper, holding same rigidly in its place.



PIPE FRAME FOR SWITCHBOARDS.

The advantages derived from this frame are evident. It protects the edge of the board from damage by ill use, and it mounts it in a fashion which permits of unlimited disposal of the slab. The back of the board is perfectly clear, as there are no angle irons or braces in the way of running wiring, bus bars, etc., and the dangers of accidental contact between live metal connections and parts of switchboard mountings, is, of course, removed. A sample of this board created such interest at the late Electrical Exhibition in New York, that its original designers—the John Simmons Company, of 110 Centre street, New York City—have decided to push it, being justified in

believing in its merits from the favorable comments of electrical experts. The Hercules frame is being placed on the market in iron and brass, with a variety of finishes, and the John Simmons Company have erected in their own extensive plant a switchboard mounted on Hercules frame, where it may be seen in actual and severe use.

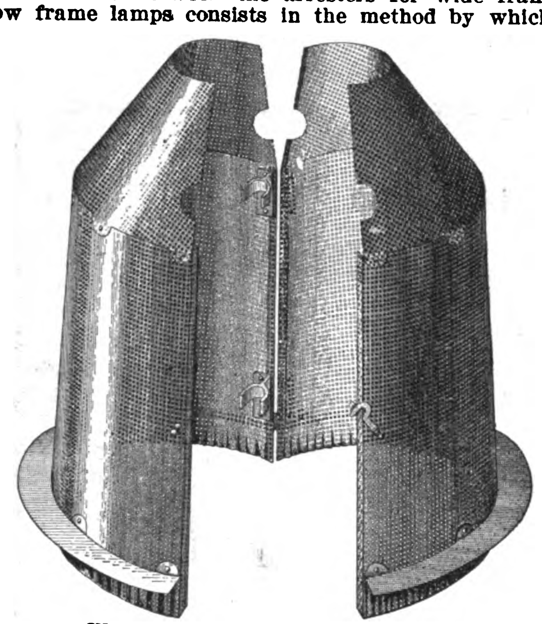
THE WESTERN ELECTRIC SPARK ARRESTER.

THESE arresters are manufactured of perforated sheet steel, neatly japanned. The body, or main part of the device has securely fastened to it a rim of sheet iron a short distance from the lower edge; this rim rests upon the top of the lamp globe. The cone-shaped top is substantially riveted to the body of the arrester, not only making it rigid, but also increasing its usefulness as a safeguard against the wandering sparks. This additional cone is a feature commended by the underwriters. The arrester has been fully tested by them and meets with their approval.

The arrester is made in two parts, fastened by hinges at the back, which allows it to be opened or closed easily when placing it on or removing it from the lamp. It is made in three different styles: for wide frame arc lamps, and for the Western Electric constant potential arc lamps.

For both the narrow and wide frame arc lamps, the total height is ten inches; the distance from the top of the arrester to the iron rim is nine inches, one inch of the arrester extending within the lamp globe. The diameter of the base is 7½ inches.

The difference between the arresters for wide frame and narrow frame lamps consists in the method by which they



WESTERN ELECTRIC SPARK ARRESTER.

are fastened to the rods of the lamp frame. The illustration shows the arrester for a narrow frame lamp, where the frame is of such a dimension as to necessitate having the rods within the lamp globe. The fasteners or clamps are shown in the cut, also the necessary holes for the rods to pass through the cone-shaped top.

When the arresters are for wide frame lamps the clamps are fastened, at the back, near the hinge, and extend outward instead of inward as shown in the cut. There are no small openings or holes cut in the cone top as the rods of the frame do not touch or enter the arrester.

The spark arrester designed for the Western Electric constant potential lamp is but 8½ inches in total height and the iron rim is ½ inch from the bottom. The clamps are inside, as shown in the illustration. The diameter of the base is 7½ inches.

These arresters are not only a safeguard against fire, but are an additional protection against insects and bugs which so frequently obstruct the arc light globes. They are unaffected by heat, and are no obstruction to the illuminating power of the lamp. They are manufactured by the Western Electric Company of Chicago and New York.

THE BOOK, by Messrs. E. P. Thompson and W. A. Anthony, on "Röntgen Rays and Phenomena of the Anode and Cathode," is selling well and rapidly, the rate reaching, it is said, a hundred per day. It is a very useful volume to the student and investigator.

ADVERTISERS' HINTS.

THE STANDARD PAINT COMPANY have recently established an office at 189 Fifth avenue, Chicago.

THE LOMBARD WATER WHEEL GOVERNOR COMPANY publish a testimonial letter from a user of their "type C" governor.

THE ELECTRIC APPLIANCE COMPANY are advertising "Armorite" conduit as being waterproof, fireproof and electrically and mechanically perfect.

J. ERLANDSEN, 172 Centre street, New York, has a well equipped shop for model and experimental work, and the manufacture of light machinery and tools.

THE C & C ELECTRIC COMPANY state that during the first six months of this year they installed 499 horse-power in motors in New York, more than any other company.

MESSRS. H. B. COHO & COMPANY, of this city, have just completed a model isolated plant for Jas. McCreery & Company, the well known dry goods house.

THE CORRESPONDENCE SCHOOL OF TECHNOLOGY, Cleveland, O., have arranged a variety of courses of home study differing in price from $14 to $120.

MR. E. V. BAILLARD, is now dealing in apparatus for the production of Röntgen rays. Full details as to prices, etc., may be obtained by addressing him at 106 Liberty street, New York.

STUCKY & HECK, ELECTRICAL MANUFACTURING COMPANY, LTD., of 35 N. J. R. R. avenue, Newark, N. J., do every variety of repair work, making a specialty of railway business.

EDWARD P. SHARP, Buffalo, N. Y., is offering some very excellent bargains in wire, switches, circuit breakers, fare registers and other electrical goods; a list of which will be sent on request.

THE GENERAL ELECTRIC COMPANY'S transformers are the result of years of experience and effort to make them perfect. Prospective purchasers are invited to make their own tests before acceptance.

THE WALKER COMPANY direct attention to the construction of their railway motors in which the bearings are placed outside of the motor, thus eliminating all possibility of the grease permeating the armature and field coils.

THE BERLIN IRON BRIDGE COMPANY illustrate in their "ad" a highway bridge constructed of wrought iron, at Jewett City, Conn. This company are constantly adding to the already long list of central stations built by them to be absolutely fireproof.

THE STANDARD ELECTRIC LAMP AND NOVELTY COMPANY have secured the services of Mr. Charles F. Reinmann as electrician, under whose direction they will continue to manufacture their lamps for decorative and surgical purposes and the many other specialties which this company carries.

STEVENSON & SON, of London, make a request in our advertising columns this week for American agencies. Mr. E. A. Stevenson, the head of the firm, is well known in this country, having been electrician to the Telegraph Construction and Maintenance Company for thirty years, during which period he has traveled all over the world and made an extended acquaintance in many countries. The firm will be glad to push abroad anything new or meritorious.

NEW YORK NOTES.

MR. ALBERT C. JAHL, manufacturers' agent, at 39 Cortlandt street, New York, is giving away to his friends at present, a useful little pocket match folder, on which is a reminder that he handles electrical supplies. Mr. Jahl has a number of specialties and will be glad to communicate with all purchasers of electrical goods.

THE HART & HEGEMAN MFG. CO., of Hartford, Conn., have appointed Mr. William Taylor, formerly of the Electrical Supply Company, of Chicago, as their representative in New York City. Mr. Taylor has secured offices in the Mail and Express Building, 203 Broadway, and will carry a full line of the well known Hart & Hegeman snap switches.

CHAS. J. BOGUE, of 206 Centre street, New York City, has issued a catalogue and price list of "American" dynamos and lamp parts. It includes a list, with prices of all the parts, and sheets of engravings with numerals to correspond. Mr. Bogue is also in the market for all the electric lighting repair work in sight. He makes a specialty of armature rewinding.

Vol. XXII. OCTOBER 14, 1896. No. 441.

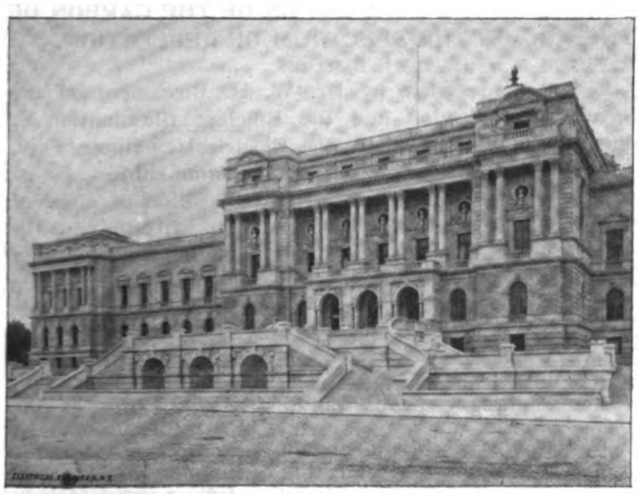
ELECTRIC LIGHTING.

THE NEW CONGRESSIONAL LIBRARY BUILDING, WASHINGTON, AND ITS LIGHTING PLANT.

BY N. MONROE HOPKINS.

CHIEF among the new attractions of the National Capital, and a place destined to rank as one of the most important Federal institutions, is the new Congressional Library, upon which time, money and talent have been unsparingly lavished. All who know the old library in the Capitol are aware of its terribly crowded condition and of the imperative necessity that has long existed for new quarters worthy of the work and adequate to the needs of that which is the official literary centre of the United States. From the fact that the library has been of great use to Senators and members of Congress, few legislators have been willing that it should be removed, but the present arrangement, which establishes the library in a magnificent new building close to the Capitol, with means of swift delivery and intercommunication, is likely to answer admirably. There is, however, additional safety in having the priceless collection of book, copyright material, documents, etc., placed by themselves, under modern methods, and in a building which embodies every possible element and feature of preservation from fire and decay.

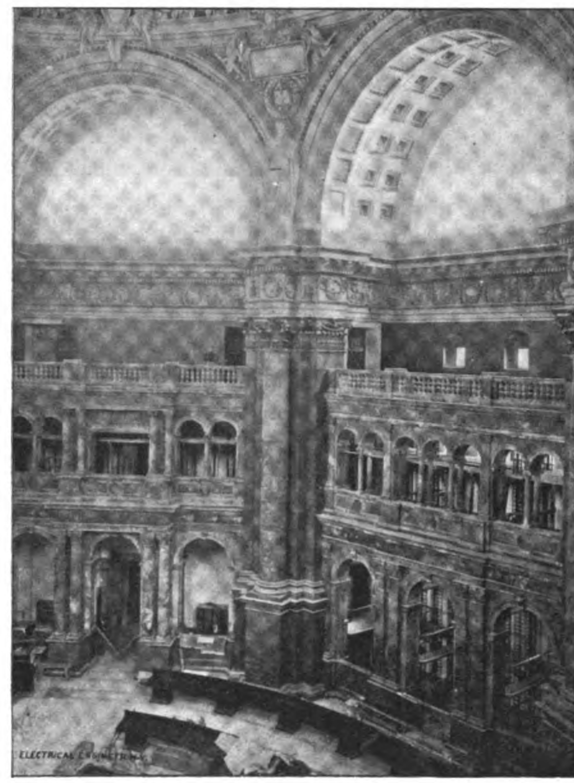
The new building for the Congressional Library at Washington was erected under the direction of the late Gen. Thomas Lincoln Casey, Chief of Engineers of the Army, who was instructed by an act of Congress of March 2, 1889, to carry out the plans for a building to cost $6,000,000, made under his supervision. The plans were evolved from those made previously by Messrs. Smithmeyer & Pelz, architects. In December, 1892, Gen. Casey placed his son, Edward Pearce Casey, then a recent graduate of the architectural department of the Ecole des Beaux-Arts, at Paris, in charge of the interior finish and decoration of the building. With an efficient staff,



THE NEW CONGRESSIONAL LIBRARY, WASHINGTON, D. C.

headed by Elmer E. Garnsey for mural painting, and Albert Weinert for sculptural decoration, this work has been steadily carried forward, and is now approaching completion, so that it is expected that the library will be ready for occupancy in February or March of the coming year.

It is impossible without far transgressing the limits of an article intended to call attention to only one important part of the engineering work to go into any account of the superb decoration that has been placed on the walls, or of the special paintings, statuary, marbles, mosaics, etc., but note cannot be avoided of one or two. American artists have never had such an opportunity before, especially for mural painting, and



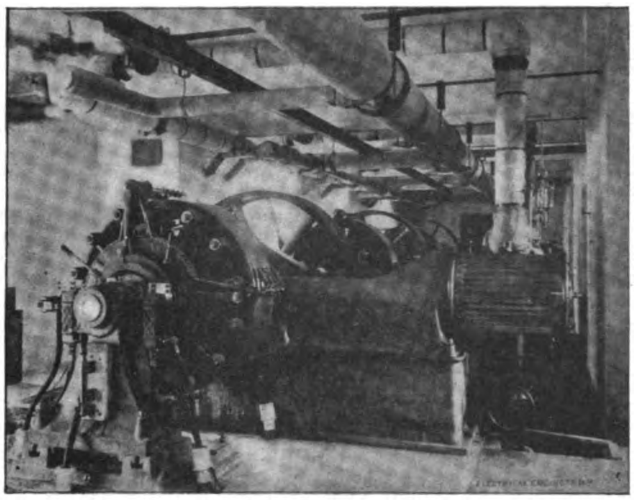
CENTRAL HALL, NEW CONGRESSIONAL LIBRARY.

the results will make a profound impression on all who see them. Moreover, the fact must be emphasized that the use of electric light renders possible the freest resort to such ornamentation and is the surest preventive of their spoiling under the action of deposits from gas, while at the same time, better illumination can be effected generally. All the paintings have been studied from the standpoint of their environment, and such work as that of Mr. E. H. Blashfield in the dome of the great rotunda or reading room is also a remarkable example of fine decorative effect, with an eye to the lighting. The collar of the dome here is no less than 150 feet in circumference, surrounding the eye of the lantern at a height of 125 feet from the ground, whence it has to be seen, unless the visitor ascends to the gallery, 30 feet higher, as shown in one of the illustrations. The details of the lighting are, of course, largely to be judged later, when the library is in use, and when all the paintings, color schemes, etc., can be seen at their best. As to the statuary, this is not less striking and fitting. Within the rotunda just mentioned are a large number of figures, among which are one of Joseph Henry, by Herbert Adams; Fulton, by E. C. Potter; Science, by John Donoghue. On the front of the building are a series of busts in niches, among them being one of Franklin, by F. W. Ruckstuhl.

The lighting plant for the new Congressional Library at Washington, which has recently been put in place, is illustrated by our annexed engravings. Bids were called for on apparatus and material, and in many instances the work of installation was carried out by government employes. An air

of thorough and substantial work prevails from the basement and cellars to the golden torch which surmounts the golden dome above the reading room.

The steam plant for lighting and heating is situated under the east parking, and the electric plant is 140 feet distant in

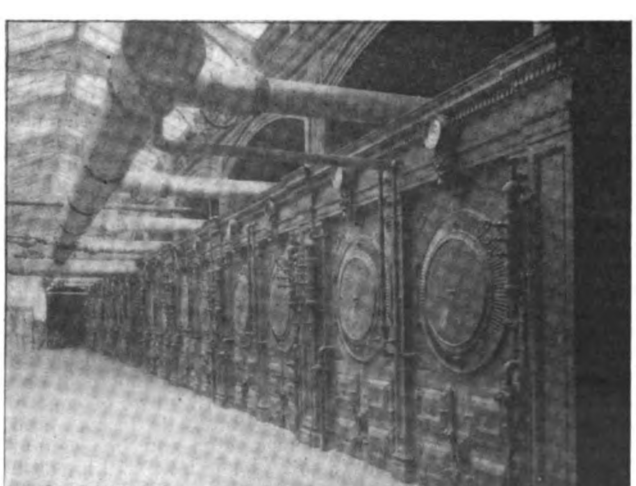


Direct Connected Dynamo Plant, New Congressional Library.

the basement. The battery of boilers is claimed to be one of the handsomest in the United States, although comparatively small. The battery consists of sixteen 60 horse-power horizontal tubular boilers, supplying steam at 90 pounds initial pressure. The boiler room is 140 feet long and 41 feet wide, with a clearance in front of the battery of 16 feet. The boilers and steam gauges were supplied by Thomas C. Basshor & Co., of Baltimore, Md., and are so arranged that any one may be thrown in or out of use, whether for lighting, heating or pumping. The feed water is supplied by a No. 7 steam pump, furnished by M. T. Davidson, of Brooklyn, N. Y. Two Davidson No. 13 pumps are also installed for the water supply of the building and the elevators. All the piping was done by government employes. The piping, valves, etc., were furnished by Bartlett, Haywood & Co., the Crane Co., and the Reading Iron Co. The stoking is to be done by hand.

The boiler room is entirely covered by a glass skylight, running from end to end. Ten-inch asbestos covered pipes supply steam to the engines, and 12-inch pipes are used for the exhaust.

The engine plant consists of four Ball engines of the straight-line, single-cylinder, non-condensing type. Three of these have 16-inch cylinders and 16-inch stroke and are di-

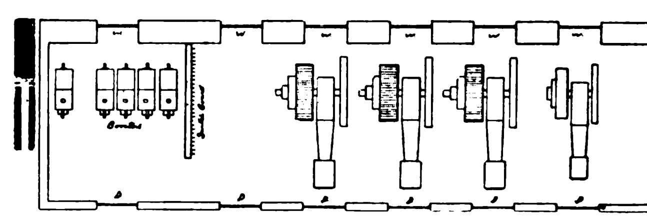


Boiler Room, New Congressional Library.

rectly connected to three four-pole Siemens & Halske generators of 100 kilowatts capacity, each with a speed of 130 revolutions, delivering the current at 130 volts. The fourth engine, somewhat smaller, is directly keyed to a General Electric six-pole machine, with a capacity of 196 amperes, at 125 volts when revolving at the rate of 300 turns per minute. Five boosters are used, which were supplied by the Northern Electrical Manufacturing Co., of Madison, Wis. These are designed for a speed of 1,..0 and a voltage of 7½. They are located, as shown in the diagram, behind the switchboard. The switchboard is of white marble, and measures 8 feet by 20, and consists of 6 panels. The indicating instruments are of Weston manufacture, and are twenty-two in number. The automatic cutouts are equipped with carbon-breaking contacts and were supplied by the Cutter Electrical and Manufacturing Co., of Philadelphia. The switches were supplied by the W. S. Hill Co., of Boston. The lower row of switches is used to throw in the boosters. The flooring is cement, with iron plate around the machinery. The wires and cables are of the "Simplex" make, and are carried throughout in the iron armor insulated piping of the Interior Conduit Co. Fourteen 30-inch Davidson fans, operated by Lundell motors, are placed in efficient localities. The wiring is on the two-wire system, and is designed for 8,000 lights. The plant, already in place, is designed for 6,000 lights.

As to the methods of illumination, it may be stated in general that the entrance to the library will be lit up by fourteen clusters of incandescent lamps, mounted on ornamental standards. In fact, there will be no arc lights used. The rotunda will be lighted from the cornices and will take no fewer than 2,800 lamps of 32 candle-power. Cornice lighting will play a prominent part throughout the building, but in some of the smaller reading rooms chandeliers and side brackets will be resorted to. In the main reading room, under the rotunda, the desks are arranged in circles and carry 12 candle-power lamps on short standards, with shades. The lighting of the halls will be by 16 candle-power lamps wired into the cornices. The effects thus obtained everywhere are extremely fine and artistically pleasing.

The book handling system includes a miniature cableway, making a tour of the book shelves and delivering books at the centre of the rotunda. The power for this cable system is an electric motor which hauls on a half-inch cable, and the section of the cableway is about two feet square. It is ex-



Generating Plant, Congressional Library, Washington, D. C.

pected that the delivery and return of books will be very expeditious and economical in other respects as well as in time.

INFLUENCE OF THE COMPOSITION OF THE CARBON OF THE ARC ON THE SPECTRUM OF REFLECTION.

BY L. B. MARKS.

In the valuable article by Dr. W. H. Birchmore on the "Spectrum of Reflection and the Efficient Illumination of Confined Space," published in The Electrical Engineer, Sept. 30, as well as in previous articles on the same subject, I note that Meyer's figures on the relative composition of different lights are taken as the basis of calculation. In applying the table for comparative purposes to the arc light, I find that the results are apt to be misleading, unless the figures are based on the performance of some special type of carbon electrode.

As pointed out by me in a paper on "Arc Carbons and the Rating of Arc Lamps," (Transactions National Electric Light Association, February, 1895), "the quality of the light as distinguished from its candle power must be carefully considered in the selection of a carbon, and in the proper operation of a lamp intended for a particular kind of illumination." A solid carbon will give entirely different results from a cored carbon; the constituency of the core, as is well known, has a very marked effect on the quality of the light. Moreover, even with the same carbons the composition of the light produced varies with different conditions of operation and is dependent on current and voltage of the arc.

These conditions cannot be overlooked in properly considering the relative values of the spectrum of reflection and the efficient illumination of confined space. If this information especially as to quality of electrodes were furnished in conjunction with the published table, the value of the results

as applied to the arc light would certainly be greatly enhanced.

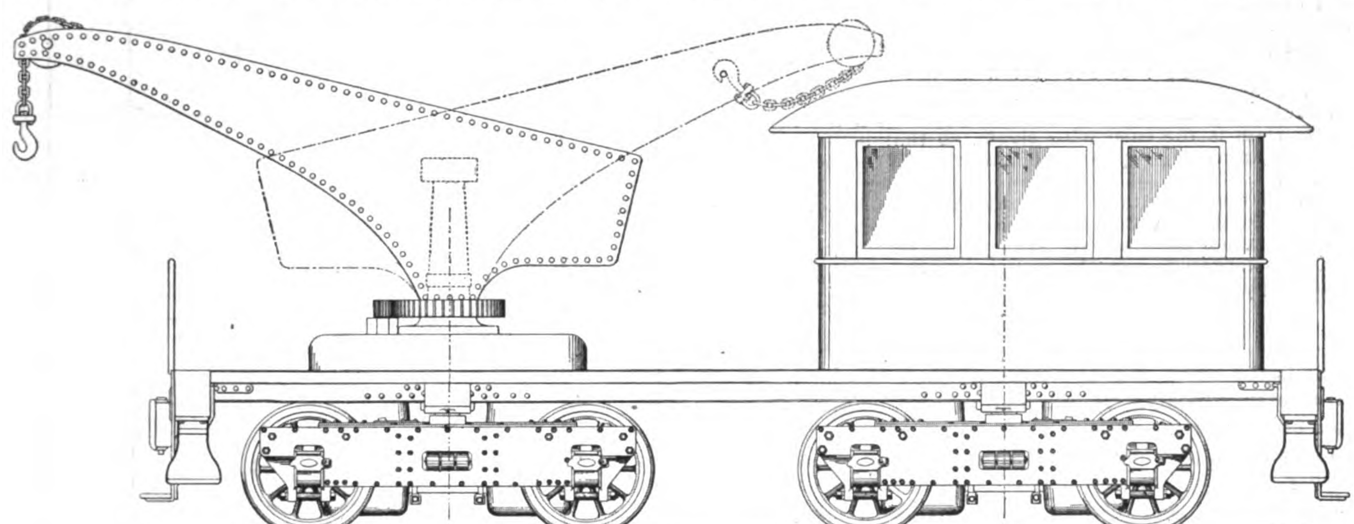
The ground taken by Mr. Marks is important and directly in line with my own studies; but in my published works no allusion has been made to the arc light as a method of illumination, my study having been confined exclusively to the filament (incandescent) lamp. In the quotation from Meyer's work the figures were given, and I quoted them as they stood, without comment, as I did not wish to mutilate the record. At some later day I shall perhaps have the time to do as Mr. Marks suggests; then I will give the data which, as he says, are so germane to the subject. W. H. BIRCHMORE.

ELECTRIC TRANSPORTATION.

COMBINED SWITCHING LOCOMOTIVE AND WRECKING CAR.

AMONG the electric railway rolling stock, which the Baldwin Locomotive Works are now prepared to build in conjunction with the Westinghouse Electric Company, is the combined switching and wrecking locomotive illustrated in the accompanying engraving.

This locomotive has the same fundamental features as the freight locomotive, namely, two trucks, one under each end, each truck being fitted with two motors, with a capacity varying from 50 to 200 horse-power each. These trucks are placed under a strong channel-iron frame, the length of which is made as short as possible, but in all cases permitting the trucks to clear each other on curves. The four-wheel switchers have the motors and axles fixed in a frame, rigid with the cab.



EIGHT-WHEEL ELECTRIC SWITCHING LOCOMOTIVE WITH ELECTRIC CRANE.

The locomotive has a crane at one end and a cab at the other. This crane is driven by an electric motor, and may have any required capacity. Switchers of this kind make excellent wrecking cars, and can be used in unloading freight.

THE JUNGFRAU ELECTRIC RAILWAY.

Having recently returned from the Wengernalp-Scheidegg, I send you some particulars as to the Jungfrau Railway, which will interest some of your readers and disgust others. At the Scheidegg Hotel I met the entrepreneur of this undertaking, M. Guyer-Zeller, who combines the functions which would in England be divided between the promoter, the directors, the engineer, the contractor, and the clerk of the works. His courage and enthusiasm are most remarkable, and his confidence in the success of his scheme is such that, of the £400,000 capital required, he has provided £40,000 out of his own pocket. He has now 150 men at work, and expects to finish this autumn the railway cutting and embankment from the Scheidegg to the Eiger. Last Thursday he finally fixed the point at which the tunneling will commence in the Eiger. The tunnel will be carried through the rock of this mountain, gradually ascending until it passes underneath the upper part of the Eiger glacier. The railway will next be taken through the Mönch until it reaches the Jungfrau, and in the rock of the Jungfrau itself the tunnel will gradually ascend to the top. Of the intermediate stations the first will be at the Eiger, the second on the Mönch, and the third near the Aletsch glacier—to which a branch tunnel will be made connecting the Bernese Oberland with the Rhone valley. The return fare from the Scheidegg to the top of the Jungfrau will be 54 francs, and it is anticipated that many persons who do not propose to go to the top will avail themselves of the intermediate stations in order to reach the Eiger or the Aletsch glacier.

The motive power will be electricity, generated by the waterfalls and streams at Lauterbrunnen and Grindelwald, from which 9,000 horse-power can be obtained. Only 3,000 horse-power is required, and it is proposed to utilize the residue for electric lighting at Berne, Thun and Interlaken.

M. Guyer-Zeller has no doubt that the cost will not exceed his estimate of £400,000, inasmuch as he personally superintends the works, and sees that no money is wasted. In six years he expects the railway to be finished. He will then be prepared to run a train every eight minutes, and he will keep a doctor at the bottom to advise passengers whether they are fit subjects for the ascent. This advice will be included in the 54 francs.—Arthur H. Spokes in "Westminster Gazette."

STORAGE BATTERY LOCOMOTIVES ON THE NEW YORK ELEVATED RAILROAD.

AS announced in our last issue, a storage battery locomotive was put in operation on the Thirty-fourth street branch of the Third avenue elevated railway. The locomtive has been in operation continuously since then, and its working is being closely watched by the railroad management.

It might at first sight appear that the storage battery locomotive could not compare in cost or efficiency with the operation of such a road directly from feeders without the storage battery, but the engineers of the Electric Storage Battery Co., who have undertaken to make this experiment on the elevated railroad, after exhaustive investigation are convinced that the advantages accruing by the use of storage batteries will prove this method far more economical than any direct feeder system alone.

If it were possible to so arrange matters that an average amount of power could be constantly supplied at an average distance from the station, a system of feeders could be installed which would concededly represent the most economical method of working a road like the New York Elevated. But it is this condition precisely which is never realized in practice; on the contrary, the nature of the traffic is such that the fluctuation of power is very great, and frequently bunching of trains occurs, which is as liable to happen at the further end of the road, as it is near the power station.

In order to successfully maintain the potential at the end of the line under such a condition of affairs, an enormous expenditure in copper for feeders would be required. It is just this ideal condition of drawing the average amount of power from the power station at an average distance from the station that the storage batteries of the locomotives are

designed to effect. It will be evident that no matter where the locomotive may be situated on a line so equipped, it will always have practically its full potential. At the farther end of the line the battery discharges more than it charges, while nearer to the power house it charges more than it discharges. The result is that the area of the conductor can be tapered more rapidly towards the farther end of the line.

Another point to be considered in this connection is that all batteries carried on the locomotives within a given distance, work in unison, so that, for instance, a train starting up from rest may, and probably will, draw current from the battery situated on trains ahead of and behind it, which trains may be at rest or coming to rest and thus be drawing no current from their batteries at that particular instant. As practically the major part of the power on elevated trains is consumed in the starting, the presence of the storage battery steadies the load on the engines at the station.

It may be argued that batteries might be distributed along the line of the road at regular intervals, which would accomplish the same object as batteries carried on the locomotive, but it will be seen that unless the number of these battery sections were very great the batteries themselves would have to be very large in order to take the maximum load which might come on any one section. Where the batteries are carried on the train itself, as in this case, no such condition can arise, as each storage battery locomotive could fully handle its own train, and, if necessary, carry it the full length of the road. It may also be argued that the same result could be obtained by placing the batteries at the power house. So far as steadying the load on the engine is concerned this would be true, but it is evident that a battery at the power house would not reduce the amount of copper required for distributing the current.

A number of other advantages are obtained by the equipment of the locomotive with an individual source of current; thus it will only be necessary to run the conductor on the straight portions of the road, no third rail being required at points where their presence would be objectionable, such as in car houses, at crossings, etc. It is calculated that with this equipment the acceleration obtainable with trains will be greater than is the case with steam, so that more trains can be run at an average speed, and hence trains can be run closer together.

With all these points of advantage in their favor, the Electric Storage Battery Company believe that they can prove to the satisfaction of the New York Elevated Railway officials that the storage battery locomotive is the most economical for their purpose.

TROLLEY HEART.

This is the name of a new disease which has made its appearance in Brooklyn, N. Y., and the following is a newspaper account of the pathology of and remedy for the disease, —as given by a physician who was interviewed on the subject: "Trolley heart is rather an indication that the nervous system is a leetle out of gear than an ailment by itself. All you need is to have your nervous system toned up a bit. You see, it comes from running the trolley cars at full speed one minute and stopping them short the next minute, and keeping up that alternation for a ride of two or three miles. The worst time for it is the rush hours at night. Then all the cars are behind time, and the motormen are trying to catch up to the time table and everybody is in a hurry to get home, and a group of people are standing on every corner waiting to get on the car. The motorman starts the car at full speed, and the sudden rush forward causes a shock to the nervous center about the pit of the stomach, which makes a sudden effort to adapt itself to the situation. Then, just as soon as the nerves have been regulated to top speed, they receive another wrench as the motorman stops the car short to let more passengers on. Thus there is a sudden strain, a sudden relaxation, and then another wrench on the nerves. It's like catching a boy by the scruff of the neck and shaking the life out of him. Apply this quick alternation of sudden starting and sudden stopping to a man whose nerves have been at high tension at his work all day and you get a wreck. The proper way for a man to go home after his work is calmly, evenly, smoothly, not by starts and jerks. That's the way trolley heart is started. Why, I have a patient who was the best father and husband in the world until they put in the trolley. After a year of it he was attacked with trolley heart, and when he'd get home at night he'd be in such a state of nervous irritation that his family couldn't stand him, and his wife was seriously thinking of suing for divorce."

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—IV.

BY LIEUT. B. A. FISKE, U. S. N.

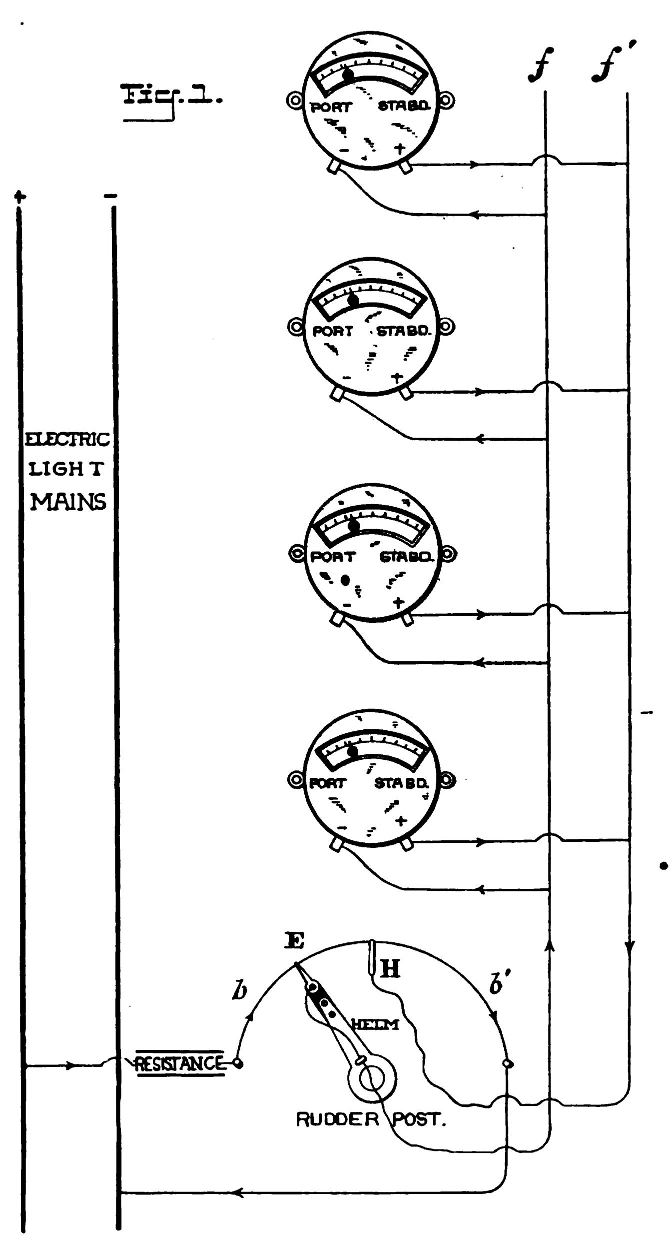
THE HELM INDICATOR.

THE office of this instrument is to indicate instantly, at certain places in a ship, the exact position of the helm. This is accomplished by means of a device rigidly secured to the rudder post, and electrically connected to any desired number of indicators.

The device secured to the rudder post consists of a strip of

HELM INDICATOR

DIAGRAM OF ELECTRICAL CONNECTIONS.



resistance wire, through which an electric current is passing and over which a metallic contact is moved by the helm; the indicators are galvanometers whose needles deflect to the right and left as the helm moves the traveling contact to starboard and port on the strip of resistance wire, the amount of the movement of said needles being proportional to the amount of movement of the helm and of the contact moved by the helm.

The principle of operation of the helm indicator is shown diagrammatically in Fig. 1. Attached to the helm and in-

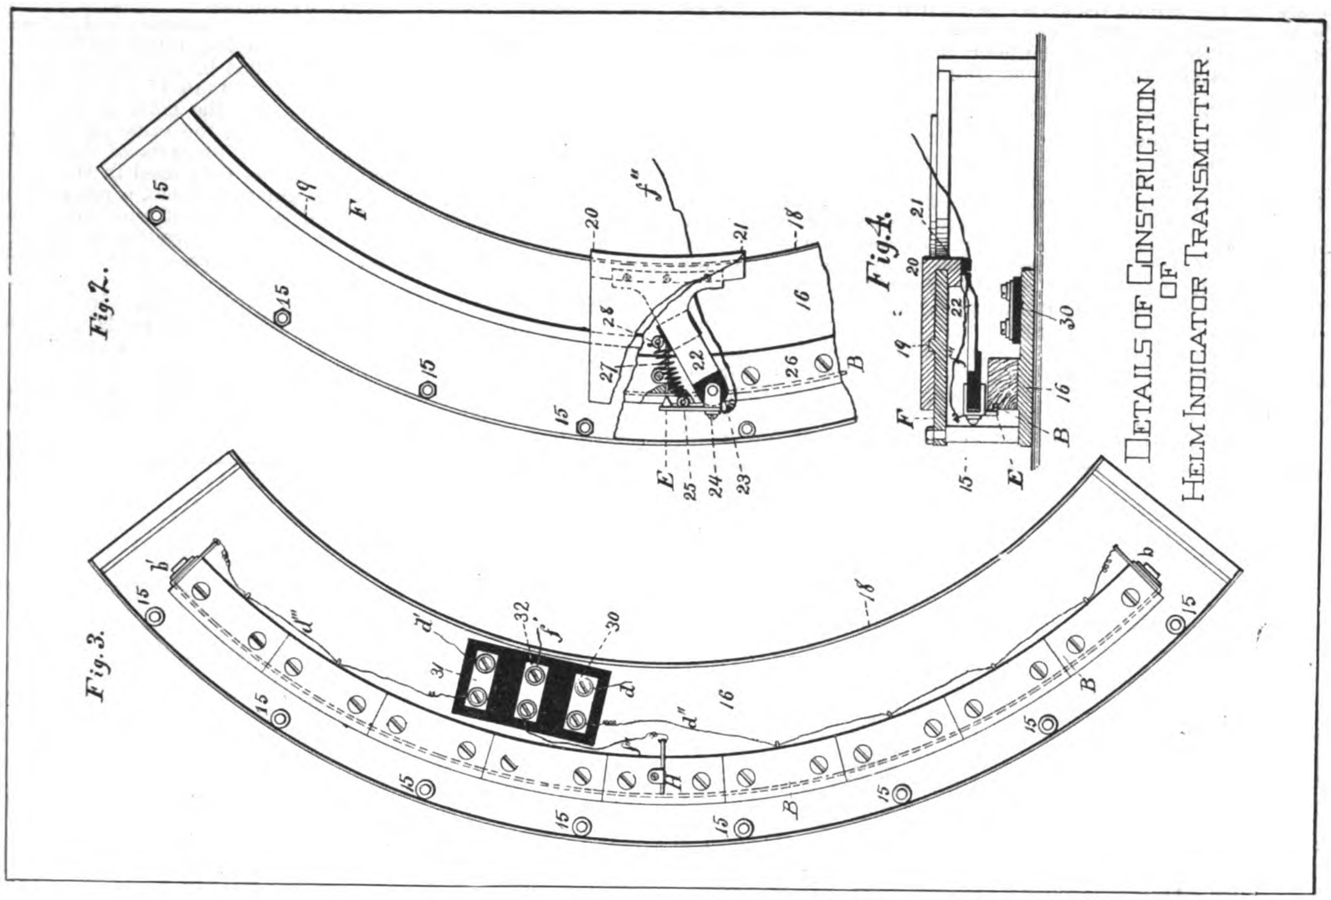


Fig. 2.
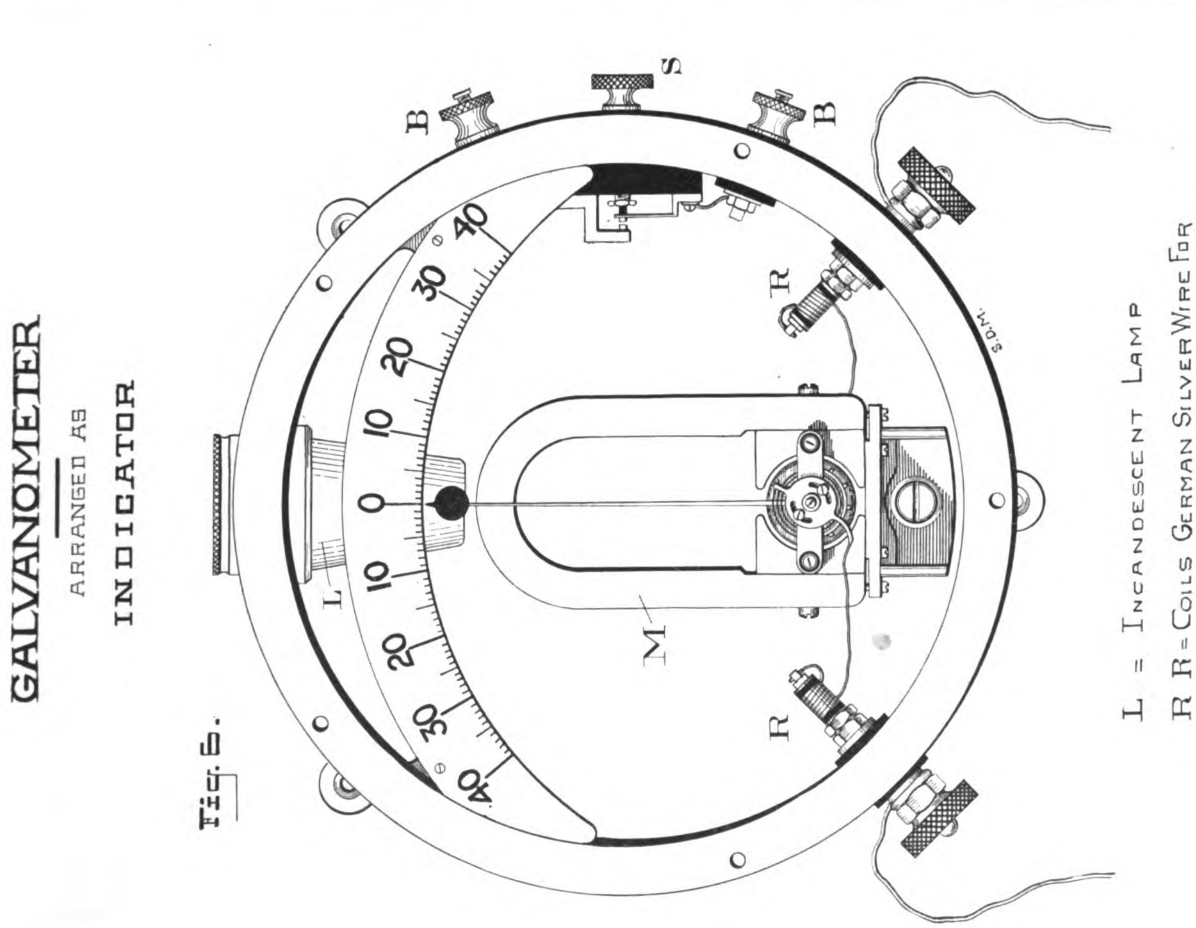
Fig. 3.
Fig. 4.
DETAILS OF CONSTRUCTION OF HELM INDICATOR TRANSMITTER.



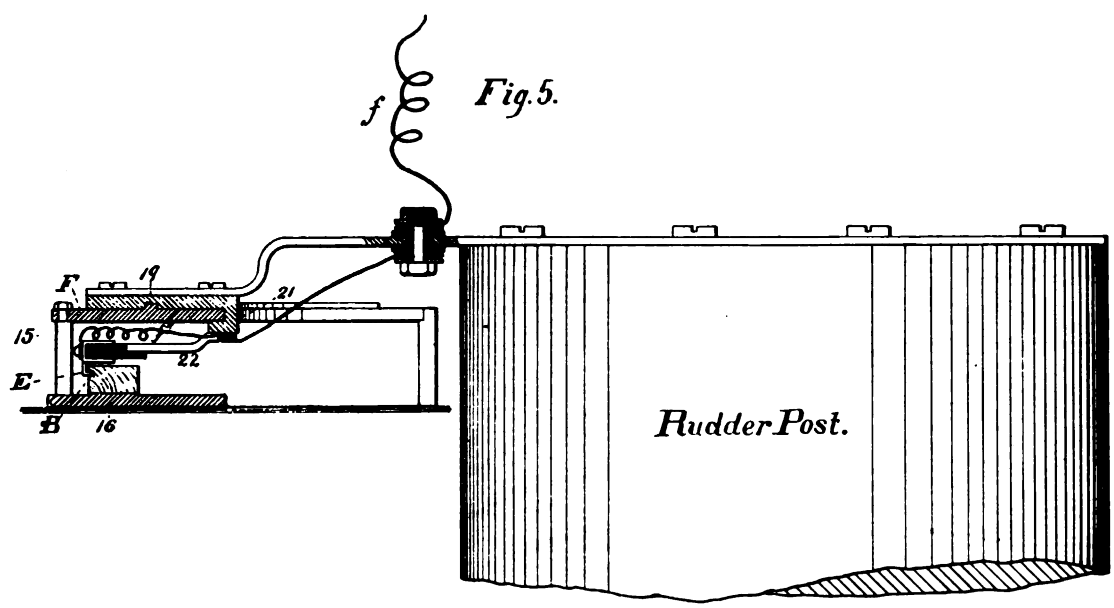
GALVANOMETER
ARRANGED AS
INDICATOR
FIG. 5.
L = INCANDESCENT LAMP
R R = COILS GERMAN SILVER WIRE FOR ADJUSTING SENSITIVENESS OF GALVANOMETER

sulated from it is the metallic contact E, which continually presses on the arc of resistance wire b b'. At the middle of this arc of resistance wire is secured and soldered a permanent metallic contact H. When the helm is amidships the traveling contact E rests on the permanent contact H, but it is moved to starboard and port of it by the movements of the helm.

A current of electricity continually passes through the resistance wire b b'. The current may be furnished by any suitable generator, such as a storage battery, primary battery, dynamotor, etc., but in the diagram it is shown as coming from the ordinary electric light mains of the ship, a suitable rheostat (resistance) being interposed to reduce the current to about 2 amperes. The immediate cause of any current in a wire being a difference of electric pressure (or potential) between the ends of the wire, it follows that there is a difference in pressure between any two points on the wire; so that if a galvanometer be connected to any two points on the wire, a current will be diverted through the galvanometer, going from the point of higher potential to the point of lower potential. In Fig. 1, as the current in the wire b b' is going from left to right, as shown by the arrow-heads, the point at E is at a higher pressure than the point at H, so that any galvanometer connected compared with that of each galvanometer, an accident to any galvanometer will not materially change the total amount of current. The current in any one galvanometer, and therefore its deflection, will increase slightly if any other galvanometer be injured and its current broken, but by an amount that is scarcely perceptible, never being more than 1° when the helm is hard over, and being nothing when the helm is amidships.

The resistance wire ordinarily used is the same as that used in the Fiske range-finder—an alloy of 70 parts of copper and 30 of nickel, nearly the same alloy as that used in the United States 5 cent piece. It is No. 22 gauge and has a resistance of about ⅛ ohm per foot. It is laid in an arc, of which the center is the center of the rudder post and the radius is about 22 inches; the radius may be varied, of course, to suit different places.

In the apparatus constructed for carrying the wire b b' and the contacts, called the transmitter, the wire is laid in a groove in an arc of wood, which is secured on a curved base plate of metal and covered by a similar curved piece of metal. The details of construction are shown in Figs. 2, 3 and 4; and Fig. 5 shows the method of securing the transmitter to the rudder post.



METHOD OF CONNECTING HELM INDICATOR TRANSMITTER TO RUDDER POST.

to E and H will be traversed by an electric current in the direction shown by the arrow-heads and the needle will move to the left. If, however, the contact E were to the right of H, it would press on a point on the wire which had a lower pressure than H, so that the current would flow through the galvanometer in a reverse direction from that indicated in the diagram and the needle would move to the right. If the contact E rested on H, as it does when the helm is amidships, the contacts E and H would have exactly the same pressure, and no current would flow through the galvanometer, and the needle would not deflect. In the galvanometers employed for this purpose, the position of rest of the needle is at a zero point in the middle of the scale.

In Fig. 1 there are four galvanometers connected in parallel (or multiple arc) to the wires f and f' which come from the contacts E and H. The reason for not connecting the galvanometers in series is that an accident to any galvanometer in action, or at any other time, would break the circuit and no galvanometer would operate. But if the galvanometers are connected in parallel, as shown, and if the wires f and f' are led below the protective deck, any accident to any galvanometer, or its leading wires, will cripple that galvanometer only. As the resistance of each galvanometer is about 60 ohms, and as the wires f and f' are of copper about No. 16 gauge, and the resistance of the wire b b' is extremely small

Referring to Figs. 2, 3, 4 and 5, the guide F is a curved plate of metal, supported by standards, 15, which rise from a base plate, 16. The plate 16, guide F and standards 15 form a box, or case, for the arc of wood, B, and movable contact point, E. Upon the upper side of the guide F is a rib, 19, which enters a groove in the under side of the traveling plate, 20. This plate has a flange, 21, which extends around the edge of the guide F. To the plate, 20, the tiller of the rudder is directly connected, so that, as the rudder is swung from one side to the other, the tiller will move the plate, 20, over the guide, F. Or any suitable intermediate transmitting mechanism may be interposed between rudder and plate, 20, to cause the stated motion of said plate and contact.

Note.—In case a needle gets bent it may be straightened with the fingers. But if, when at rest, it does not point to 0, and yet is straight, the trouble is that the little clamping screws near its pivot, shown in Fig. 6, have slipped. In this case these screws must be slackened and the needle turned carefully on its pivot until it points correctly, and then the little screws re-tightened.

Note.—Fig. 6 shows coils of resistance wire inside of the case for adjusting the sensitiveness of the galvanometer. Where extreme accuracy is required it becomes necessary to have an adjustable resistance outside the case as in the Fiske range-indicator, in order to compensate for sudden variations in the strength of the magnet due to changes of temperature. But this refinement is not considered necessary in helm indicators or steering telegraphs.

Weight of transmitter, 35 pounds; weight of indicator, 22 pounds; diameter, 10 inches; resistance, 60 ohms.

To the flange, 21, is secured an arm, 22, the end, 23, of which is of insulating material and carries a pivoted bracket, 24, which supports a short arm, 25, on the end of which is the contact point E. The arc, b b', of resistance wire is embedded in a groove in the edge of the wooden arc, B, which is secured by screws to the upper side of base plate, 16. Also to said blocks is secured the fixed contact point H. A spiral spring, 27, connected to the arm, 25, and to an eye, 28, held in an insulating block on arm 22, serves to hold the contact point E against the resistance wire b b'.

The wires d and d' are secured to plates 30 and 31, and from those plates the wires d'' and d''' lead to the terminals of the resistance b b'. The wire f' connects to a similar plate, 32, and from this plate the wire f''' leads to the fixed contact H. The wire f, Fig. 5, is connected to a plate on the arm extending from the rudder post to the traveling plate, 20, and from this plate the wire f'' leads to the contact piece E.

The resistance wire b b' should be kept covered with a thin film of oil or vaseline. If this is done the friction of the traveling contacts will not cause the wearing away of the contacts or the wire, and the contact will move smoothly without jumping.

In case of trouble with this apparatus, the cause will be found in nine cases in ten to be a faulty contact.

In some cases the details of the transmitter have to be changed slightly in order to make it fit in certain places; for instance, the sliding plate, 20, sometimes has a flange fitting around the outside edge of the base plate, 16, instead of around the inside edge.

The galvanometer usually employed in the helm indicator, steering telegraph and engine telegraph is like that used in the Fiske range-finder and range-indicator and is illustrated in Fig. 6. The current passes through a light coil of wire in the form of a bobbin pivoted between the poles of a stout magnet, M. It is held normally at a position of rest in the middle of the scale by two spiral or volute springs, one at each end of the pivot. The effect of a current going through the coil of wire is to turn the coil in one direction or the other according to the direction of the current, and this tendency is resisted by the springs, so that the needle assumes a resultant position, in which the force of the springs just balances the magnetic force operating between the magnet and the current, the movement being small or great according as the current is small or great.

The galvanometer is mounted in a heavy water-tight case. In the helm indicator and steering telegraph circuits, the cases are usually made of heavily japanned cast iron, both for strength and for the reason that the iron case acts as an armature to the magnet inside, and decreases the effect of the magnet on any compass in the vicinity. But an indicator should not, if possible, be closer to a compass than three feet.

The iron cover carries under it a strong circular plate of glass, held on to it by an iron ring. The circumference of the glass is encircled by a rubber band, between which and the glass, white lead is placed to insure water-tightness. For the same purpose, white lead is thickly laid in the grooves for the glass plate in the cover and the iron ring, so that, when the iron ring is screwed on to the cover (the glass being between), the complete cover thus formed is itself water-tight. Before screwing the cover on to the galvanometer case, a rubber gasket is secured to the case by shellac. When the cover is screwed on, it forces the gasket into such intimate contact with the case that it cannot afterwards be pulled off without tearing. Shellac and white lead are omitted between the cover and the rubber gasket, in order to make it easy to take off the cover, if it becomes necessary. To make the case water-tight, therefore, the cover must be screwed on tight.

A space of about $^1/_{32}$ inch is left between the glass and the outer iron plate in order to protect the glass against any blow that might be transmitted through the iron plate. To drain off any water that might run in between the glass plate and the iron plate, a quarter-inch hole is cut near the lower part of the iron plate. The helm indicator was given a year's test in service on board the armored cruiser New York. It has since been installed in the battleships Indiana and Massachusetts, using five indicators in each ship, the year's test having been passed successfully. It is now being installed in the Texas and is to be installed in the Brooklyn.

To illuminate the indicators of the helm indicator and steering telegraph for night use, a small electric lamp L is introduced into the case as shown in Fig. 6. It lies within a stationary water-tight glass receiver, or globe, so that it can be taken out for inspection when desired, and replaced by another lamp, if necessary. The lamp may be lit by the current from a storage battery, or from the electric light mains of the ship, connected to the binding posts, BB, resistance being interposed to cut the current down to about ⅓ ampere. The lamp is lighted by turning the water-tight switch shown at S, Fig. 6. The scale is printed on cardboard secured on a brass gauze translucent backing.

The copper wires connecting the instruments should not be less in size than No. 16 American gauge.

ALTERNATE CURRENT TRANSFORMERS.—IX.

BY DR. J. A. FLEMING, F. R. S.

(Concluded.)

THE following table shows us that practically the largest conductor which should be used in connection with alternating current work is a cable having an outside diameter equal to a 19/12 cable, and that if the cable has a greater diameter, then its resistance to alternating currents of a frequency 100 is sensibly different from its resistance to continuous currents. In the next place, with regard to capacity, suppose that a concentric cable is formed by putting one cylindrical tube in the interior of another cylindrical tube, the space between the tubes being occupied by non-conducting material or dielectric having a specific inductive capacity equal to K; then, if R_0 is the radius of the inside of the outside tube, and R_1 is equal to the radius of the outside of the inner tube, and if L is the length of the tubes, the capacity of this concentric cable in microfarads is given by this expression:

$$C = \frac{KL}{2(\log R_0 - \log R_1)} \cdot \frac{1}{2{\cdot}303 \times 10^5}$$

Then, as regards the value of K for paper insulation, such as is used in the Ferranti cables, K has a value very nearly equal to 3; but, if India-rubber is used, then K has a value very nearly equal to 4. On calculating out these values for most ordinary cables used for the conveyance of high tension alternating currents, it will be found that for such insulating materials as paper, Fowler-Waring composition, or various resinous substances, the capacity of the cable is generally about one-third of a microfarad per mile.

TABLE OF RESISTANCE OF HIGH CONDUCTIVITY ROUND COPPER CONDUCTORS.[1]

Cable. Strands and size.	Total cross-section area in square inches.	Resistance in ohms per 1,000 yards. For continuous currents.	For alternating currents. Frequency 100 ~ per second.

From what has been said above with regard to the resistance effect, it must be noted that in the construction of a concentric cable the maximum thickness of the copper conductor cannot be more than about ½ inch. In cases where larger currents have to be conveyed than can be carried through the

[1] The wire numbers are given in British Standard Gauge.

equivalent of a 19/12 cable, it is desirable to employ two concentric cables in parallel. Let us consider, then, the capacity effects. If a long concentric cable is connected to an alternator, the far end of the concentric cable being insulated, it is found that an electric current flows into and out of the cable, which may be sufficient to light one or more incandescent lamps. This is called the capacity current of the cable, and it is a current flowing across the dielectric or non-conductor from one copper member to the other. If C is the capacity of the cable measured in microfarads, V, the difference of potential between the two copper members measured in volts, and if P represents $2 \pi n$, where n is the frequency, then the capacity current, I, is given by this expression:

$$I = \frac{C, p, V}{10^6}.$$

Thus, for example, supposing a cable, having a capacity current one-third of a mile capacity, has a potential difference of 2,000 volts between its inner and outer conductors, and P equals 500, then the capacity current is one-third of an ampere, or equivalent to the lighting current of one 8-candle-power lamp. Hence, in very large concentric systems, this capacity current going out of the station may amount to a considerable value. We have then to consider briefly what are called the resonance effects. If an alternator is separately excited so as to give a certain potential difference at its terminals, suppose 2,000 volts, and if a long length of concentric cable is connected to this alternator, the far end of the cable being insulated, then it will be found that such cable, when associated with the alternator, may greatly increase the electric pressure between the terminals of the alternator, and that for a certain critical length of the cable a very marked rise in pressure may take place. The same will be found to be the case if a long length of concentric cable is connected to the high pressure side of a step-up transformer being excited from a 100-volt alternating circuit on the low pressure side. Accordingly, in testing concentric cables, the engineer must always be on his guard against this resonance effect. Suppose, for instance, it is desired to test whether a certain length of concentric cable will stand 2,000 volts, the most natural method of doing this would be to connect the high pressure side of a step-up transformer, raising the volts from 100 to 2,000, and to serve the low pressure side of this transformer from a 100-volt circuit. The inexperienced person might naturally suppose that this would invariably place upon the cable a pressure of 2,000 volts, but under certain conditions, depending upon the capacity of the cable and the inductance of the transformer, the pressure might rise far beyond 2,000 volts between the two members of the cable, and the only method of making sure that this is not the case is to have an electrostatic voltmeter kept connected between the inner and outer members of the cable as the pressure is gradually increased. Then, in the last place, not only are there the resonance effects above referred to, by which a concentric cable when switched on to an alternator or transformer permanently raises the pressure, unless the exciting current of the alternator is reduced, but there are certain very important initial effects which take place at the moment when a concentric cable is switched into connection with either an alternator or another live cable. If a condenser is connected with an inductive resistance, it can be shown that at the moment when this system is brought into connection with the source of alternating electromotive force, if the connection is made at a particular instant with respect to the phase of the electromotive force, there is an electrical oscillation set up in the combined condenser and inductive resistance, the amplitude of the oscillations of current greatly exceeding those which would exist when the steady state has been established, and oscillations of potential difference occur at the same time, the result of which is that the difference of potential between the two plates of the condenser will undergo a periodic change, the amplitude of the oscillations of which is, however, in the initial stage much greater than that of those which take place when the whole system has settled down into a steady condition under the influence of the impressed periodic electromotive force. Suppose, then, that a series of transformers are connected to the two copper members of a concentric cable, and that the concentric cable is, as usual, lead covered and steel armored, with a layer of insulation between the lead covering and the outer copper members. As already stated, there is a certain capacity in the concentric cable between the inner and the outer members, which will be generally something like one-third of a microfarad a mile, but, at the same time, there will be a capacity between the outer member of the concentric cable and the lead casing or the earth; and this capacity between outer and the earth, as it is called, is very much larger in general than the capacity between the inner and outer; it may be ten times as great. Hence, if the transformers are connected between the inner and outer conductors we may regard the primary circuits of the transformers, which are inductive circuits, as connected in series with a condenser, which is formed of the outer members of the cable and the lead covering. If, therefore, such a cable, with transformers attached to it, the secondary circuits of which are unloaded, is switched into connection with the omnibus bars of an alternating current station, the connection between the inner member of the cable with the proper omnibus bar being made first, then, at that instant, an electromotive force is impressed upon the system, consisting of the inductive primary circuits and the condenser in series with them. For a particular phase of the impressed electromotive force, it can be shown that oscillations of potential are set up in the condenser, causing a periodic potential difference between its two sides to be greater than that due to the steady action of the periodic electromotive force. This sometimes results in breaking down the insulation between the outer members of the concentric cable and the lead covering, and as this insulation is generally in all cases made much thinner than that between the inner and outer members of the cable it is not unfrequently pierced. Alternating current station engineers are very familiar with failures of such concentric cables occurring between the outer members of the cable and the earth. The remedy for this is one of two things, first, the outer the concentric cable must be connected to its proper omnibus bar first before the inner member of that concentric cable is connected. If this is done, then it is impossible to set up destructive oscillations of pressure between the outer members of the cable and the lead covering. Another remedy is to introduce in the circuit with the inner member of the concentric cable a variable inductance, which is gradually removed in such fashion that the inner member of the concentric cable is not connected suddenly with the source of potential, but is connected through a choking coil, the choking quality of which is gradually removed. This can be done in the following manner: A large transformer is arranged so that its secondary circuit can be gradually short-circuited by lowering two lead or iron plates into an insulated tub of water; the primary circuit of this transformer can be connected in series with the inner member of the concentric cable, which is to be brought into connection with the system. The operation, then, of connecting the long concentric cable to the omnibus bars is as follows: The series transformer first has its secondary circuit opened, its primary coil is then connected in series with the inner members of the concentric cable to be connected, and with the proper omnibus bar, the outer member of the concentric cable is then connected with the other omnibus bars; the plates on the secondary circuit of the series transformer are then gradually lowered into the water, and when the secondary circuit of this series transformer is practically short-circuited the primary circuit of the transformer is also short-circuited, and the transformer is then removed, leaving the main in connection with the omnibus bars. The operation, moreover, is performed in such a manner that there is no rush of current into the cable, and no possibility of setting up violent oscillations of potential between the outer members of the concentric cable and the earth. In no case should long concentric bars be connected to omnibus bars, or to other parts of an alternating current system without some such process as the above, of gradually setting up the full current in them, or else the risk of piercing the outer insulation of the concentric cable is very considerable. Engineers, in connection with alternating current stations, should always be on their guard against these initial effects, and remember that long concentric cables, with transformers connected to them, possess a quality which resembles inertia, and that currents can no more be started and stopped instantly in these cables and transformers than heavy machinery can be started and stopped at once.

In addition to the initial effects taking place in cables, I showed, in 1892, that there were certain initial effects, called current rushes, taking place in transformers when suddenly switched into connection with a live cable. Under some circumstances, depending upon the phase of the electromotive force in which the switch is closed, a strong rush of current may take place into the primary circuit of a transformer, the maximum value of that current rising to twice the maximum value of the current when the steady state is established; and, under some conditions, in switching off a transformer, there may be a certain rise in the difference of potential between the parts of the primary circuit and the iron case or secondary circuit which may pierce the insulation. If a large current is flowing in an inductive circuit, and a switch is suddenly opened, interrupting that circuit at an instant when the current has its maximum value, then a large inductive electromotive force is set up in that circuit, which may result in breaking down the insulation between parts of that circuit.

The effect arises from the same cause that frequently destroys the insulation of a field magnet of a continuous current motor or dynamo if the field magnet is suddenly switched off at a moment when the magnet is in a state of excitation. Broadly speaking, as a practical rule, it should be remembered that long concentric cables, having transformers lightly loaded connected to their ends, should never be suddenly switched into connection with alternators, or switched off, but should always be put into connection with the source of electromotive force through a regulating resistance or inductance, so arranged as to prevent or check the formation of any oscillations of current other than those due to the natural period of the impressed electromotive force. In the early days of the working of many large alternate current stations, many difficulties were experienced, owing to the failure of large transformers, and the piercing of long concentric cables, which were due to these causes; but experience has now shown how to overcome these difficulties, and to prevent any of these disastrous initial effects. In many cases cables and transformers, which suddenly fail when switched into connection with the circuit, after being idle for a time, have really been injured at the instant when they were last switched out of connection with the working system, owing to the rise of potential that has taken place at the instant when the current was interrupted at a particular instant during its phase. Hence the removal of a cable from a working system at the omnibus bar, or at any intermediate point, must always be effected with the same care as the connection of a cable, and in no case should a long concentric cable, whether connected to transformers or not, be switched on or switched off from the live omnibus bars of the station abruptly. This, of course, does not apply so much to short lengths of a few hundred yards as to long lengths of one or more miles; but it behoves the engineer always to be on his guard against these sources of failure.

The time will not allow me now to develop at any greater length these points, and in closing this brief discussion on the construction and action of transformers, there is no need to emphasize the fact that much has perforce been omitted, owing to the limits of our time, which a complete treatment would necessarily include. I have endeavored to direct attention rather to a few principal practical considerations, and to portions of the subject not quite elementary in character, and to assume, as I said at the beginning, that the fundamental principles were already familiar to most present.

Great as has been the progress in ten years in alternate current working, no one would be so rash to assume that we have reached the limit of its improvement. The practical perfection of the transformer placed in the hands of electrical engineers an instrument of enormous utility and power for effecting the distribution of electric current. Large as may be our indebtedness to those whose scientific and constructive ingenuity has brought about this advance, we must at the same time remember, with due meed of honor and praise, the pioneering experiments of Paul Jablockoff and Lucien Gaulard, in 1887 and 1882, which, even if not the first suggestions for the employment of the induction coil in electric lighting, certainly forced the attention of engineers to consider closely the value and use of that device, and the service it might be brought to render in the solution of the problems of public and private electric supply.

ELECTRIC SEALSKIN.

The first consignments of sealskins reached London, now the greatest market and distributing center of the world's yearly crop of fur, a few weeks since, but the sales are not likely to be held before December. Although the skins from British Columbia and the Behring Sea, as well as from the Prybilov and Copper Islands, are much smaller than those of last year, it is quite possible that prices will not be raised in proportion to the depreciated catch. This is largely due to the fact that what is called "electric seal" has found its way into common use to such an extent that the value of true sealskin has become lessened in the eyes of the furriers' fair customers.

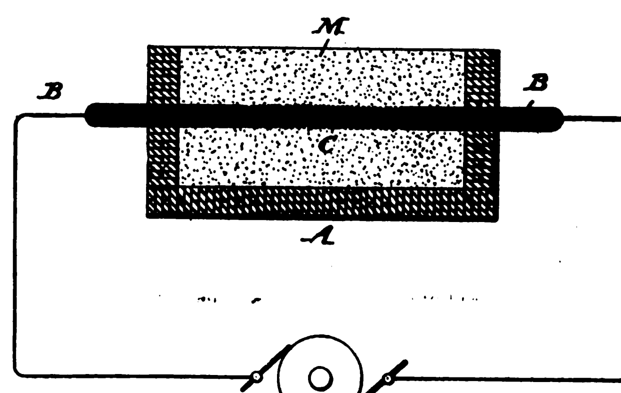
Electric seal is nothing more than the skin of the ordinary French tame rabbit scientifically treated. The skins are first dressed to obtain pliability and softness, the coat afterward passing under a machine of extraordinary delicacy, which shears down the stronger and coarser hairs, giving at the same time a softness and "flow" to what is left. The dyeing is skilfully managed to give artful gradations of golden brown under the surface, while the final stage of manipulation is assisted by electricity, really marvellous machinery removing any undesirably stiff hairs that may have been left by the first machine. It is curious that only the skin of the domestic rabbit can be so treated.

I am told by one who ought to know that sable and ermine, as well as chinchilla, will, this coming season, dispute the supremacy of sealskin. No successful imitation of the rare Russian sables has yet been found, and it is likely that these beautiful skins will bring a more exorbitant price than ever this year.—"Philadelphia Public Ledger."

GRAPHITE FROM THE ELECTRIC FURNACE.

ONE of the most remarkable as well as useful of the products of the electric furnace which has reached the stage of commercial availability is the well known carborundum of Mr. E. G. Acheson, now being extensively manufactured by the Carborundum Company, at Niagara Falls. From the beginning of his experiments in the production of carborundum, which is a silicide of carbon, Mr. Acheson noticed the formation of graphite among the products of the carborundum furnace, but the quantities formed, though of great purity, were comparatively small. Encouraged by these results Mr. Acheson proceeded to investigate the conditions under which graphite is formed in the carborundum furnace, and as a result of this work he is now enabled to produce this valuable material in any desired quantities.

In converting carbon in its ordinary conditions as found in commerce and in nature into pure graphite by subjecting the carbonaceous material to a high temperature, such as is obtained in an electric furnace, it would naturally seem that



ACHESON'S METHOD OF PRODUCING GRAPHITE IN THE ELECTRIC FURNACE.

the purer the carbon used in charging the furnace the more abundant would be the yield, and it would perhaps be generally considered that there was a direct transformation or conversion of the carbon into graphite. Mr. Acheson has discovered, however, that such is not the case, and that the percentage of graphite produced by highly heating pure carbon in an electrical furnace is insignificant and impracticable. He has also discovered that in order to produce pure graphite from carbonaceous materials there is an indirect conversion, and that the act of formation of the graphite is more in the nature of an act of dissociation of the carbon from its combination with other materials than a conversion of the ordinary carbon into graphite, and that as a preliminary step the carbon has to be combined chemically with some other material. Thus he has found that if the carbonaceous material or carbon used in the process contain a considerable proportion of mineral matter, or if it is mixed with a certain proportion of oxid, such as that of silica, clay, alumina, magnesia, lime or oxid of iron, etc., and subjected to the treatment described below, the yield of graphite is enormously increased and the product is most satisfactory.

The accompanying diagram represents graphically a longitudinal vertical section through the center of the furnace, A, built of firebrick. Carbon rods, B B, connected with the source of electric energy, pass through the end walls of the furnace; a granular carbon-core, C, extends the length of the furnace between the carbon rods, and this core is surrounded by the mixture, M, of carbonaceous material and oxids, out of which mixture the graphite is to be produced.

The mixture, M, is composed of powdered coke, sand, salt and sawdust, the coke forming about fifty per cent., by weight, of the mixture, and these materials are thoroughly mixed and introduced into the electric furnace surrounding the core of granular coke, which is of sufficient size to conduct the current through the mixture at the beginning of the operation and until the graphite is formed in sufficient quantity to act as a conductor of the current. The furnace being

thus prepared, the current is turned into it with an amperage sufficient to impart to the core the requisite heat. As the temperature rises, the resistance of the core decreases, and thereby more current passes through it. The size of the core and the current strength must be sufficient and so proportioned as to raise the temperature of the core to a point where the portions of the mixture immediately surrounding it will be subjected to the chemical and other changes necessary for the production of the graphite out of the carbon or coke contained in the mixture of carbon and silica. As the temperature of the core rises the heat radiating therefrom passes into the mixture, and the carbon unites with the silicon of the sand to form a carbid of silicon. When this chemical combination takes place, there is formed around the core a layer of amorphous and crystalline carbid of silicon or silicide of carbon, which in its crystalline form is called carborundum, and as this process continues this layer or zone of carborundum is gradually increased.

Upon continuing the application of the electric current, producing a very high temperature, much higher than is necessary for the formation of the silicide of carbon or carborundum, the carbon is dissociated or separated from the carbid of silicon into the graphite form, while the silicon is volatilized and passes off in the form of vapor. As the destruction of the carbid goes on and the graphite is formed around the core the graphite becomes a conductor and the core is increased as the graphite is formed, so that the intense heat necessary to the production of the graphite is transmitted to the surrounding carbid, and more carbid is destroyed and graphite deposited on the core until the graphite formation has extended outward to a point so close to the walls of the furnace as to endanger them from the intense heat produced.

The process may thus be said to embody a complete cycle, by means of which pure carbon in its amorphous condition is converted into free pure carbon in its graphitic form, and in accomplishing this the amorphous carbon is first caused to form a chemical union with one or more elementary bodies, as the silicon, and this chemical compound is then disassociated or separated into its elements, the carbon assuming the graphitic form and the elementary body, as the silicon, being volatilized.

Mr. Acheson has found that when in carrying out this process a carbonaceous material is used containing an unusual amount of ash the oxid added should be correspondingly diminished, and if the carbonaceous material is so impure as to contain more than the requisite proportion of foreign matter a proper charge may be made by the addition to such impure carbonaceous material of a sufficient amount of ordinary hard coal, coke, or the like. He has found it also advisable to use a carbonaceous material containing as little volatile matter as practicable, as when such material is present energy is wasted on destructive distillation.

Various strengths and conditions of current may be used. As an example, with the graphite furnace indicated, having a core seven feet long by four inches wide, composed of granular coke or carbon, the current at starting is about six hundred and fifty volts and fifty amperes. As the graphite is formed and becomes a conductor, extending the core, there is a change, say, to one hundred volts and one thousand amperes before the completion of the run or operation and the production of the entire amount of graphite.

THE DE LAVAL ELECTRIC IRON SMELTING PROCESS.

We print below an interesting account of the new process for reducing iron directly from its ores by the electric arc, communicated to "The Iron Age" by Mr. F. H. Daniels, general superintendent of the Washburn & Moen Manufacturing Company, who has returned from a trip to Europe, which included a visit to Sweden:

Dr. De Laval has become one of the best known Swedes and is regarded as their greatest mechanical and metallurgical genius. He is perhaps best known to the general public as the inventor of the separator for extracting cream from milk and as the inventor of the De Laval steam turbine. He has also lately brought out the lactator, a machine for milking cows, which is in successful operation near Stockholm. His most recent undertaking in the direction of reducing iron ore to metallic iron by means of an electric arc has excited widespread curiosity through Europe, especially so in Sweden. The fact that Dr. De Laval has been in the past a very successful inventor and that his inventions have returned large revenues, both to himself and his associates, leads many conservative engineers in Sweden to believe that his experiments have already been or will be successful, and that the final outcome will be a successful and commercial process for reducing iron ore directly to metallic iron or steel. It is stated on good authority that a company has already been formed, with a capital of 20,000,000 kronor, and that Dr. De Laval's financial backing is already assured, the most largely interested being men whose names are well known all over the world. Dr. De Laval commenced his experiments something like three years ago at Trollhattan. During this period he has been assisted by a competent corps of mechanical engineers and metallurgists, and it is evident these experiments have produced results, from the fact that he has purchased one side of the entire water power at Trollhattan, which is made up of four falls, an aggregate horse-power of from 60,000 to 70,000. He has also purchased at considerable expense very much larger water powers in the North of Sweden.

It is interesting in this connection to note that quite a number of the iron and steel works in Sweden have become so interested in the possibilities of this process that they have purchased all of the available water power in their vicinity. It is a matter of fact that water falls are in demand at the present time in Sweden, and in favorable localities can be disposed of on very advantageous terms.

It is understood that this process does not contemplate the manufacture of iron sponge. It is proposed to either manufacture steel direct or manufacture a cast product which can afterward be utilized in the Siemens-Martin furnace. In a general way, it is understood in Sweden that Dr. De Laval's process consists in mixing pulverized iron ore with carbon, probably in the form of pulverized peat, and subjecting the same in some form of a rotating cylinder to heat, after which it is brought into direct contact with an electric arc of tremendous power, which reduces the ore to metallic iron. The melted iron then flows into a large and highly heated furnace, where it can either be manufactured directly into steel or cast in any suitable form for further treatment.

WATER FOR BOILERS.

BY M. W. DANIELSEN.

THERE never was a time when it was more necessary to look after the equipment of the mill or shop than the present, and we are glad to see that some manufacturers are putting their establishments in shape, so as to be able to meet the closest kind of competition. It would be difficult to define the exact advantage a good equipment has over a poor one—the ordinary expression, "covers a profit," does not fully describe it. But involved in the matter is a point which is sometimes overlooked, namely, good water to correspond with the efficient boiler equipment.

If one desires to locate a factory or central station, one of the most important factors, which should lead to the acceptance or abandonment of a certain locality, is the question of quantity and quality of the available water supply. The boilers will have to be supplied with suitable water, stock is to be cleansed by water, water may have to be used as a dissolving agent for chemicals, and there should be water fit to be used for miscellaneous purposes.

Some steam users usually consider that if pond water is used, there is less trouble likely to arise than if spring water is fed into the boilers. Pond or river water is almost sure to bring with it, at times, vegetable matter or other troublesome materials. It is well known that works that use spring water have more trouble with scale, than the boilers directly fed from ponds or brooks, for spring water has not the same chance to mix and dilute its scaling properties as water which flows some miles before used, and water which will make the clearest bleach, is sure in most cases to make a very hard scale.

The water which evaporates from the surface of the ocean and has again been precipitated as rain, under the influence of cold air currents mixing with the warm vapor-laden currents from the ocean, is practically free from dissolved inorganic impurities or salts. Yet in its descent through the air it absorbs all the impurities contained therein, soot, dust and organic matter and germs of all kinds; it is likewise rich in ammonia and nitrous acid. It purifies very easily in consequence, when it is kept in cisterns.

The inorganic substances mainly met with in waters are lime, magnesia, oxide of iron, potash and soda, in combination with sulphuric acid, phosphoric acid, hydrochloric acid, nitric acid, carbonic acid and silicic acid or silica. I have always found that rain water is the ideal boiler water and use it in my boilers. In order to keep a basin of such water in good condition, I rig up the system of pipes shown in the accompanying diagram, Fig. 1.

The pipe, B, is covered by a strainer, A, through which the water enters. The current flows upward through C, and downward through D, into a drain. To the pipe, C, is at-

tached an overflow outlet, E, which is adjusted so as to keep the water line a few inches above the level of the pipe, C. Thus there is a downward pressure into the submerged outlets, slightly in excess of the upward thrust which is necessary to effect an escape and serves to keep the water supply in good shape for the boilers, as the water is drawn from the lower part of the basin, and not wholly from the top as usual.

If the rain water passes through soil its composition changes

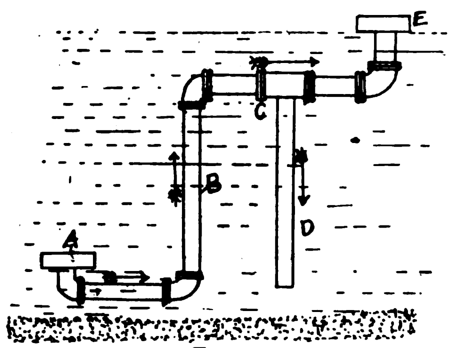


FIG. 1.

considerably, but the changes wrought differ with the composition of the soil. In the first place the soil acts like a filter and removes much of the natural impurities of the rain water, especially the undissolved portion, the soot, the germs and organic debris. Then, however, it may act chemically on the dissolved substances like nitrous acid and ammonia, and finally the soil yields certain substances to the water, which increase the dissolved impurities of mainly inorganic nature, but frequently also inorganic matters.

In passing through a soil derived from the disintegration of granite and gneissy rocks, the water takes but little inorganic material, and such a water remains therefore soft.

In passing through layers of old sand stones they are likewise soft; formations consisting alternately of younger sand stone and limestones, especially the latter, impart generally great hardness to water.

I have found it beneficial to run greasy water through an

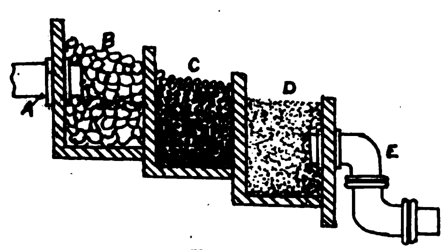

FIG. 2.

arrangement like that shown in Fig. 2, before feeding it to the boilers. Any carpenter can build the chambers, B, C, D, of wood, in the first of which should be put stones, in the second gravel, and third sand. The water should be filtered through this, entering the pipe, A, and going to the boilers through the pipe E.

LITERATURE.

WHAT IS ELECTRICITY? By Prof. John Trowbridge, S. D. New York: Appleton & Company. Illus. 12mo, illus. 315 pp. Cloth. Price, $1.50.

We don't know, and we never shall know, is the answer that Prof. Trowbridge gives to his own question; but the book is something more than a miserable and irritating confession of human ignorance. It sets forth in a series of naturally sequential chapters the outlines of knowledge in regard to electrical phenomena, and winds up by saying that: "We have already strong grounds for believing that we live in a medium which conveys to-and-fro or periodic movements to us from the sun, and that these movements are electro-magnetic, and that all the transformations of light and heat, and, indeed, the phenomena of life, are due to the electrical energy which comes to us across the vacuum which exists between us and the sun—a vacuum which is pervaded by the ether, and which is a fit medium for the transmission of the electro-magnetic waves." To have gone thus far is to have done a great deal, and Prof. Trowbridge's pages are full of the data upon which certainty is assured, no matter what may be the ultimate interpretation. Chapter 21 is particularly interesting in its comments upon the nature of the sun as the source of heat and therefore of all our forms of energy, including electricity, and as being itself nothing but an electric oven on a vast scale. Many of our readers will enjoy this book as a review in popular form of current physical science, and they have plenty of friends to whom they can offer it as a helpful exposition of the subject.

POOR'S MANUAL OF RAILROADS. New York: H. V. and H. W. Poor. Price, $7.50.

This, the twenty-ninth issue of the manual, is more valuable than ever. It presents the statistics of more than 4,000 companies, of which over 1,200 are in the street railway field. A remarkable feature is the inclusion of industrial securities, and State and municipal investments. The book is a mine of information.

"GODEY'S MAGAZINE" has begun a short series of articles on "Benjamin Franklin." It is a relief to know that his were the victories of peace, and that there will be no pictures of battle and bloodshed in which he will appear as the chief actor.

LETTERS TO THE EDITOR.

THOMSON WATT METERS IN CANADA.

I have read Mr. Haskins' defense of the Thomson wattmeter and would state that all electric meters in Canada are inspected and sealed by the Government and remain sealed for 6 years, when they are again tested.

This, you must admit, changes the matter considerably, and I am sure when Mr. Haskins makes some experiments with these meters which have been sealed up for any length of time, the results will not be so accurate as those obtained from the experiment he describes.

THE KINCAID STREET ARC LAMP REFLECTOR.

I notice in one of your London contemporaries a brief note on my street arc lamp reflector, described in the Electrical Engineer of August 5, 1896, which the editor criticizes on the score that "if the mirrors are accurately designed the result would be to give four narrow beams of light. The width of the beams would also be much more narrow than the roadway."

In answer to this I would say that if such were true there would certainly be reason for serious objections to the use of the reflectors. But, as experience proves, an accurate mirror of that description is a commercial impossibility. And again, the source of light, the crater and carbon tip is very far from being a mathematical point in size, producing altogether a beam more or less diverging.

I found, however, that with the foci and arc coinciding, the beam was rather too narrow, and widened it by slightly altering the focal points of the reflectors.

To widen the beam in the immediate vicinity of the lamp I found it advantageous to gradually depart from a true parabolic curve at each extremity of the reflectors. This had the desired effect without unnecessarily widening, and thereby diminishing the intensity of that part of the beam cast by the perfect curve of the middle portion of the reflector, and intended to light the most distant points. As the beams of light diverge from a comparatively narrow source, it must necessarily follow that in the immediate vicinity of the lamp there will be shadows, to light which I would use a convex, annular, translucent reflector placed directly under the side reflectors on an ordinary globe holder.

Of the direct rays of light incident upon this translucent reflector part will be reflected over the dark areas, and the remainder in passing through will be diffused over the roadway underneath.

There being "no strong local light," there can be no objection on that point. In driving toward the light the reflected light was no more severe on the eyes than that from the naked arc, as was proved by removing the reflectors. Only at distances exceeding 200 or 250 yards does the greater penetrating power of this light become apparent.

OCEAN TELEPHONY.

AUTHORITIES in matters telephonic have so long and so often, and with good reason, pointed out the insuperable difficulties that stand in the way of telephony through submarine cables between Europe and America, that work in this field has up to the present time been monopolized almost exclusively by charlatans. When one considers the inexorable laws which govern the speed of transmission in cables, it does give one a sharp twinge of surprise to have the possibility of accomplishing the feat pointed out by a man whose work in the past entitles him to unquestioned respect, and whose utterances are not to be lightly brushed aside. Encouraged by the results reached with the channel cable, forming part of the telephone line connecting London and Paris, Mr. Preece, in his paper, read before the British Association, describes the results obtained with an improved type of cable, which lead him to the belief that at no distant day he will be able to hold telephonic communication between England and Germany over submarine cables 225 miles in length. Mr. Preece goes even so far as to hint at the possibility of transatlantic telephony with a type of cable identical with the old Edison halfmoon lighting conductors.

Perhaps the most marked feature in the construction of the proposed cable is the adoption of paper insulation immediately surrounding the conductor. We dare say that had such a proposition been made but five years ago it would have been ridiculed in England, yet we think America may, with justice, claim to have brought about the adoption of this method of insulating telephone cables, which has had a marked influence on the method of manufacture of telephone cables the world over. As one looks back scarcely a decade to the time when the specifications for telephone cables called for no lower electrostatic capacity than .2 microfarad per mile, and considers that to-day manufacturers are guaranteeing cables with close on to .07 microfarads, the great strides made and the possibilities which such a reduction in capacity opens up are apparent. Mr. Preece's plans may be looked upon as visionary, but we hope that he will carry them out and test them to the fullest extent. It has been argued in some quarters that nothing would be gained, in a practical way, by transmitting messages telephonically over the Atlantic cables, as the best types of such cables at the present time, working duplex, transmit with almost as great a speed as speech could be transmitted and recorded by telephone, having due regard for accuracy, which is here of special importance, since the larger part of cable work is done by code, in which one word bears no relation to the next. We are not among those who look upon the question in this light, however. As an

achievement alone, the work would be well worth undertaking, if it could be carried out at a reasonable cost, and we feel certain that once accomplished, a use would be found for transatlantic telephone cables, just as a use has been found for that magnificent network of long distance telephone lines, which have brought all of our cities east of the Mississippi within hailing distance of one another, notwithstanding the previously existing telegraph lines.

WORK FOR THE N. E. L. A.

THE National Electric Light Association exists because there is good reason for its existence. We doubt if any other such organization has, during the present year, given so many proofs of its usefulness to the industry represented or of desire to conserve and build up the constituent members and promote their prosperity. First and foremost, of course, among its achievements stands the electrical exhibition in this city, which has already made a deep impress on the electrical arts, and which has given decided stimulus to the central station industry by showing that all the improvements are not exhausted and that many new things remain to be done. This was a great work, but as if to show that it was not seeking mere spectacular glory, the association has turned at once to the directly practical and technical sides of the industry, and has suggested reforms that everybody must heartily welcome. The spirit and the attitude of the president of any association must count as a large and determining factor in work of this character, and it is only fair that the keen intelligence and profound knowledge of the conditions involved, brought to bear on the duties of his office by Mr. Frederic Nicholls, should be recognized and heartily commended.

We publish elsewhere in this issue the report, ad interim, the second of the kind presented by President Nicholls since his election only last May. We also give an account of the conference called by him on the subject of socket and lamp-base standardization. Here was a vital question "in the air" and waiting for somebody to grapple with it. Our own pages have been full of discussion of it, but a newspaper is a forum, not an executive body, and it required that the lamp manufacturers should themselves set the great work of uniformity and standardization on foot and push it to perfection. If Mr. Nicholls' incumbency of office bore no other mark of effort than this beginning of the great period of standardization in electric lighting details it would be honor and credit enough. But there are other things to be attended to, and we are satisfied that no good work will escape the association's vigilance and laudable ambition, with its present energetic executive.

STORAGE BATTERY LOCOMOTIVES.

WE have no doubt that many electrical engineers, on reading the illustrated account of the placing of a storage battery locomotive on the elevated railways in New York, which appeared in our last issue, shrugged their shoulders at the idea, and mentally classed this experiment with numerous preceding ones in electrical work as foredoomed to failure. We must confess that at first sight the proposition to operate storage battery locomotives in competition with the direct system of conductors seems somewhat difficult to carry out, but nevertheless the projectors of this exceedingly interesting trial feel convinced that they can demonstrate the feasibility of the system. On another page we print a discussion of the benefits claimed for this system, which merits the closest attention of those interested in electric railway work, whether for elevated or surface traffic. The cost of feeders on any extended system of railway, the management of which has due regard to the character of its service, becomes more and more onerous as traffic increases, while, on the other hand, the fluctuating nature of the power drawn from the central station is a matter of well known loss of efficiency at that point. To equip each motor car or locomotive, as the case may be, with an independent source of current, albeit small in capacity, unquestionably removes the objection which the present existing method of operation involves. It is true that a large proportion of the many troubles incident to electric railways could be avoided by the introduction of storage batteries at the central station itself, or distributed at suitable points on the line, but the ideal method, it must be admitted, is that proposed by those undertaking the present work on the elevated railroad in New York. It is, of course, still too early to look for a definite result regarding the experiment, but we consider the attempt a most important one, and one which should meet with all encouragement at the hands of the electrical railway fraternity.

BRAINY LITTLE JAPAN.

DURING the past few months this country has been favored with the visits of three or four highly intelligent Japanese engineers and technical experts, who have given special attention to American electrical development with the object of ascertaining how far their country can be placed in line with our own in the utilization of modern inventions and ideas. It now appears that one of the first moves resulting from the inquiry is the extension of the telephone system, upon which a sum over 12,800,000 yen is to be spent by the government in a term of seven years, or, say, $1,400,000 a year. The public is eager for telephonic service, and it is said that in Tokio alone there are now 2,000 subscribers and 2,000 applicants waiting for connection with the exchange. In many other cities similar conditions exist, while the long-distance service will in particular receive attention. Another point to which the commissioners visiting this country paid special attention was that of power transmission, the plan being to employ for lighting and railway work many of the fine waterpowers scattered about Japan. In all this the courage and progressive spirit of the Japanese is to be greatly admired, and their enterprise will bear fruit generously.

SOUND MONEY LITERATURE.

SOME excellent work in the diffusion of sound money literature is being done by Mr. Allen R. Foote, editor of "The American Exporter" of this city. He has long made a study of the financial problem and of the influence of national monetary legislation upon industry and commerce. We have before us now copies of letters sent by him to gas and electric lighting companies in important States, fifteen in all, and of another letter to street railway companies in the same regions. He points out the vital necessity of sound money to all such enterprises, and invites their co-operation in distributing literature on the subject. This literature has been carefully prepared and is of small cost, and we trust it will be largely used. The subject is one demanding public education, and Mr. Foote is doing a good work that should be liberally availed of and assisted right now.

TELEPHONY AND TELEGRAPHY.

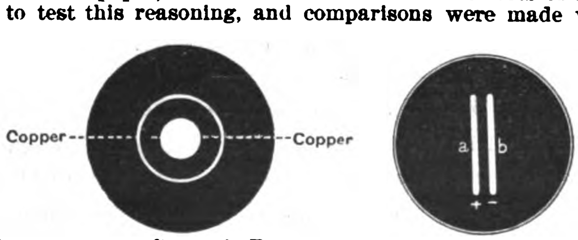
ELECTRICAL DISTURBANCES IN SUBMARINE CABLES.[1]

BY W. H. PREECE.

The author's paper was divided into two sections, the first treating of telegraph and the second of telephone cables. In the former he traced the changes which had been brought about in the speed of signaling in the Anglo-German cables, leading up to the latest type in which the cable, consisting of four stranded conductors, has each conductor core surrounded by a brass tape which entirely shields the conductor from electrostatic induction. The possible rate of working of the 1896 cable is 33 per cent. better than that of the 1891 cable.

In the section devoted to telephone cables the author stated that the total energy expended in any circuit in a given time may be considered under three heads: 1. That expended in overcoming resistance. 2. That expended in producing the electric field. 3. That expended in producing the magnetic field.

In each case we must consider the energy stored up and that dissipated. The former tends to retardation, the latter to work done, and therefore to reduction of efficiency. Careful regard must be paid to the directions in which the different disturbing forces act, for it may be that they oppose each other, and direct the energy into the original channel under modified and more favorable conditions. Thus, if the whole effect of the electrostatic field is neutralized by that of the electromagnetic one, the total energy developed is expended on the circuit itself, disturbances are eliminated, and the service improved. This is the case of a metallic circuit having a microphone transmitter at one end and a telephone receiver at the other. The capacity of such a system will tend to store up a portion of the energy of each current, but the electromagnetic induction between them will tend to supply the deficiency. If the two wires of the loop be far apart the influence of mutual induction will be much less than that of capacity. As they approach, the electromagnetic induction must increase at a greater rate than that of the electrostatic induction, until, finally, at the limit where they coincide, the one must exactly neutralize the other. This, perhaps, is better seen if we consider the case of a concentric cable; for, in this case, the number of lines of electric force does not increase, while the number of lines of magnetic force cutting the other conductors does increase rapidly as the outer conductor approaches the inner. The maximum induction from each source must take place when the two conductors are infinitely near each other, and this maximum must equal the primary current, for it cannot exceed it unless there were fresh creation of energy. Thus, as the separating dielectric becomes smaller and smaller, the two effects approach each other closer and closer, until, at absolute contact, they annul each other. The result must be that if these be the only conditions present, the time constant must diminish as the two conductors approach each other, and in the limit it must disappear. Twenty miles of concentric cable (Fig. 1), insulated with paper, were made and laid in the streets of London to test this reasoning, and comparisons were made with



FIGS. 1 AND 2.—PREECE'S EXPERIMENTAL TELEPHONE CABLE.

ordinary parallel cylindrical conductors, insulated both with gutta percha and with paper and air. The result was very encouraging; but an unsuspected difficulty arose from the want of symmetry of the capacity of each conductor and the earth. The insulation resistance of each conductor was also different, and the result was that when the concentric cable was joined to overground wires, serious disturbances were experienced in the working circuits, which, however, were remedied by crossing the conductors of the concentric cable at several points, so that each side of the circuit was sometimes the inner and sometimes the outer conductor. This, however, is a cure that could not easily be applied to a submarine cable. It is clear that in such a cable symmetry of capacity with earth and of insulation is essential.

The experiment with the concentric cable shows that we have to consider not only the capacity between the two conductors, but that between each conductor and earth. Symmetry can be produced if the conductors be shaped and arranged as in Fig. 2. Only a certain number of lines of electric force, dependent on the voltage present, can emanate from each conductor. The closer a and b (Fig. 2) are to each other, and the further they are from the earth, the greater the number of lines between the conductors and the fewer to the earth. The electric field is, in that case, confined almost entirely to the space between a and b.

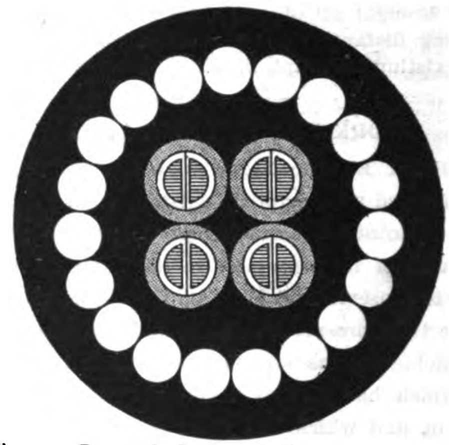


FIG. 3.—PREECE'S PROPOSED TELEPHONE CABLE.

The problem resolves itself into a practical question: What is the best form to give the cable with our existing experience and our available materials? My present solution is given in Fig. 3. The conductors are insulated first with paper and then with a thick coating of gutta percha. Paper only exists between the conductors. The cable is sheathed and compounded in the usual form. There are four circuits, instead of two, as at present in the London-Paris cable.

With such a cable I have little fear of speaking between England and Germany (about 225 miles); but to test the practical points that arise in the manufacture of such a cable it is proposed to make and lay a short one to the Isle of Wight. If my reasoning is correct, and so far experiment has confirmed it, then not only ought we to be able to speak to great distances, but the type of ocean cables must be revolutionized, for what is true for telephony must be equally true for telegraphy. Cables such as those across the Atlantic might, with the same weight of copper, be made to transmit a greater number of words per hour than they do now.

[1]Abstract of a Paper Read Before the British Assoc. at Liverpool.

SEEING BY ELECTRICITY.

BY ED. WAGEMAN.

THE results of my experiments with the problem of seeing at a distance by means of electrical appliances of different construction have been as follows:

First of all an instantaneous transmission I have not yet been able to obtain; the person or the scenery must be immovable at least for a minute in front of the transmitter, and the light strike right in front of the same. In the receiver appear white spots and shadows, grouping themselves into a sort of daguerreotype of a clear and distinct nature. If from any cause the positions in front of the transmitter are in the least changed, the outlines in the receiver become blurred, assuming new outlines only after a lapse of about one minute. In no instance was the least trace of a transmission of color observable. The line, having capacity, made the outlines at times unduly enlarged. The same effect resulted from an electrical disturbance in the vicinity of the wires and the apparatus.

I have come to the conclusion that the problem will not be successfully solved by the employment of only one wire. In my experiments three wires are employed, one wire each for the direct and the alternating current, while in the return wire the one current is superposed on the other. The employment of iron wire will very likely not be possible, and the employment of relays or electromagnets must be avoided as

much as possible or their construction altered to suit the conditions.

An ordinary 16 candle power Edison incandescent lamp gives by far better results than the Crookes tube with Röntgen rays. I am unable at present to perceive how to get the color transmitted and reproduced. Selenium pure and simple will not accomplish it; besides, the selenium film alone does not seem just exactly the proper medium to reproduce color.

In my opinion, the solution of the problem will necessitate the co-operation of the physicist, electrician and chemist, and of the latter, one who has made the study of the hydrocarbon group a specialty. It will not be accomplished by one man alone, and those investigators who have at their disposal the largest and best laboratories and money to back them up will get ultimately closest to the solution of the problem.

THE HISTORY OF THE HARRISON INTERNATIONAL TELEPHONE CO.

IN Chicago last week Judge Grosscup issued an injunction restraining the Harrison International Telepnone Company and the Harrison International Telephone Construction Company from disposing of any of the company's assets. The injunction was issued for J. A. Williams and D. J. Young, of Fort Smith, Ark., as complainants. The list of defendants is a long one, and includes many men prominent in national politics and finance.

In the bill of complaint it is stated that the Harrison International Telephone Company was incorporated under the laws of Illinois in December, 1892, with an authorized capital of $80,000,000, divided into 800,000 shares. This stock was to be non-assessable. Stock was subscribed by the following: Edward M. Harrison, $30,000,000; Charles M. Ferree, $20,000,000, and Albert L. Stone, $30,000,000. It was claimed at the time that E. M. Harrison owned certain patents which would give the company almost a clear field in the telephone business of the country.

After the stock was issued 500,000 shares were set aside as treasury stock, and the remaining 300,000 were to be divided among the three original subscribers. In order to place the company in such a position that its stock would sell easily, the following men were each given 20,000 shares of treasury stock, and their names used as directors and active managers of the company: Stephen B. Elkins, R. C. Kerens, George R. Peck, William Warner, Patrick Egan, Howard M. Holden and Charles Foster. The stock given to these men was entered in the company's books as donated. Stephen B. Elkins was elected president and Patrick Egan secretary.

It is asserted by the complaint that these men were fully aware of the fraudulent issue of stock, and that their names were to be used to give the company prestige in the eyes of investors. It is also stated that after their election this board of directors took active charge of the affairs of the company and were fully aware of the fraudulent transactions of the company.

From that time the sale of stock assumed enormous proportions. It was heralded that the Harrison Company would enter into active competition with the Bell Company. Buyers of stock were in many cases widows, small trust companies and others who had been led into the company because of the eminence and respectability of the board of directors.

In March, 1894, the telephone company virtually passed out of existence, as its directors transferred the right to sell, use and introduce its electrical appliances to the Harrison International Telephone Construction Company. The stock was reduced one-half, but to such straits had the company come that the stock did not appreciate. The directors of the old company, in order to relieve themselves of liability, transferred a controlling stock interest to L. E. Ingalls for a nominal sum.

The complainants owned stock in that branch of the general company known as the Arkansas Telephone Company, with a plant valued at $25,000. This stock, upon representations of stability, was transferred for that of the Harrison International. May 4, at the annual meeting, it was learned that the tangible assets of the Harrison International Company would not amount to more than $100,000, and that these were about to be transferred to the construction company. A receiver is accordingly asked for to wind up the affairs of the telephone company, and until such a receiver is appointed the complainants asked for an injunction to prevent the sale of tangible assets.

SAVANNAH, GA.—A new exchange is to be built at Savannah by the Southern Bell Telephone Company.

POWER TRANSMISSION.

PRESENT STATUS OF THE DISTRIBUTION AND TRANSMISSION OF ELECTRICAL ENERGY.[1]—II.

BY DR. LOUIS DUNCAN.

CONTINUOUS CURRENT LOW VOLTAGE DISTRIBUTION.

SOME of the most important stations supplying incandescent lamps are operated on the three-wire continuous current system. In the last few years a considerable advance has been made in the sale of power for motors from these stations, and this has increased the revenue and has given better average output. The tendency in this country has been in the direction of using storage batteries in such stations, and abroad practically every continuous current station uses batteries. It would unquestionably be more economical, in many instances, to use single stations, to transmit power from these stations to centers of distribution, where batteries may be located and to distribute from these centers on a three-wire system. A case in point is the system used at Buda Pesth, where the energy is distributed from the central station to rotary transformers at sub-stations, these rotary transformers feeding batteries, current being distributed from these batteries on a three-wire system. The reports of the operation of this station show that it is both economical and successful, and it might well be copied by some of the companies in this country.

ALTERNATING CURRENTS FOR LIGHTING.

Alternating currents have been employed for lighting in this country, and they have been especially valuable where a district is to be supplied in which the distances are considerable as compared with the number of customers. It has been almost the universal custom to supply small transformers for each consumer, and while the average size of transformers is greater now than it was a few years ago, yet they are comparatively small. No power has been supplied from such stations, and although alternating arc lamps are used to a limited extent, yet the number is not increasing, and in some cases continuous current arc lamps have been substituted for the alternating. Under these conditions the load on the station is even more variable than in the case of a continuous current supply where motors may be employed, and the constant loss due to the large number of small transformers used, places this system at a disadvantage as compared with the continuous current system. Abroad in the last few years most of the new stations that have been built use continuous currents, although some years ago the greater proportion of them were alternating current stations. It is also the custom abroad to use sub-stations with large transformers for distribution, thus doing away with a considerable part of the constant loss due to the small transformers used here. It is not possible, at this present time, without greatly complicating the system, to obtain a steady load on the station, and the only question that arises is the value of sub-stations, and the possibility of using some form of alternating current other than the single-phase.

METHODS OF ELECTRICAL TRANSMISSION.

Coming to the question of transmission of electrical energy as distinguished from the supply to customers from distributing centers, there have been great advances made in the last few years, and these mainly through the introduction of multiphase alternating currents. Single-phase alternating currents permit the transmission of power to long distances and its distribution for lighting purposes. It is also possible to supply power from such circuits to large motors working under a steady load. It is not possible, however, to distribute power economically for ordinary uses. The introduction of multiphase alternating systems, where two or more alternating currents are employed, the currents differing in phase, has completely changed the situation with respect to long distance transmission. I shall consider briefly the possibilities of such systems and their value as compared with any direct current system.

CONTINUOUS CURRENT TRANSMISSION.

The first long distance transmission plant was operated by the continuous current system, and even now plants are being built in which continuous current of high potential is used to transmit energy to distances up to 15 miles. If we consider the relative cost of the copper in the line for a given amount of power transmitted and for a given maximum potential be-

[1] Presidential inaugural address read before the American Institute of Electrical Engineers, Sept. 23, 1896.—Abstract.

tween the conductors, we will find that the relative amounts for the continuous current and the different alternating current systems, will be as follows:

Continuous Current	100
Single-phase Alternating	200
Two-phase "	200
Three-phase "	150

We see then that the continuous current has a marked advantage over the alternating current systems as far as the cost of copper is concerned. There are, however, certain practical disadvantages belonging to this system. The high voltages necessary for long distance transmission make it impossible to distribute the current at the receiving end without first reducing the voltage. With continuous current this can only be done by employing a rotary commutator of some kind. A plan which has been practically and successfully used has been to run a number of dynamos in series at the generating end of a line, while at the receiving end are a number of motors, also arranged in series, which are used to drive other generators to give the required type of current and the desired voltage. It has not been found possible to make either dynamos or motors of any great output, as there are practical difficulties in running dynamos of high potential where the current taken from them has a considerable value. M. Thury, has installed a number of continuous current transmission plants that have apparently given excellent results. At Biberist, a transmission of 15 miles is employed. At Brescia, 700 horse-power are transmitted over 12 miles at a maximum of 15,000 volts. M. Thury states that generators for 45 amperes can be constructed up to 3,000 volts, and he thinks that 4,000 could be successfully used. These machines, however, are small when compared with the 5,000 horse-power dynamos in use at Niagara, for instance, and where the transmission is a large one the great number of machines necessary would be a serious objection to this type of transmission. It will be seen that the greatest possibility of trouble, in such a transmission, lies at the ends of the line, in the generating and receiving apparatus. It must be recognized, however, that this system has been successfully used and has given excellent results in a few cases of transmission. Its great advantage lies in the decreased amount of copper as compared with the alternating systems, and in the absence of induction effects, which are a drawback to alternating current transmission.

TRANSMISSION BY ALTERNATING CURRENTS.

A large proportion of the transmission plants that have been installed in the last few years have been of the alternating current type. These have, as a rule, given satisfactory results, and the installations that are now being erected or planned are almost exclusively on an alternating current basis. The great advantage of this system lies in the fact that it is possible to change the voltage of the current without the use of rotating apparatus, and at once economically and safely. If we compare this method with the continuous current system, we will see that to obtain an alternating current of the required pressure at the receiving end of the line, we would use the same number of transformations required by the continuous current system. We have the great advantage, however, that our changes in voltage have been obtained by the agency of stationary apparatus, which is much cheaper, is more efficient and is safer than that required in the continuous current system. It is possible to increase the voltage by means of transformers to almost any value with perfect safety and with an efficiency as high as 98 per cent. or 99 per cent. If then our alternating current, when it has been reduced at the receiving end, is as valuable for distribution as the current obtained by the direct current system, there will be no doubt that alternating transmission has great advantages over continuous currents.

There is no single-phase motor in successful commercial operation that does not require to be started from rest by some outside means. This prevents a single-phase current from being used at the present time for power distribution; and as, in most transmission, the distribution of power is an important item, single-phase currents are not suitable for this purpose. In a two-phase system the currents are usually carried on separate pairs of wires, while in the three-phase system, three wires are generally used, a common return being unnecessary as the sum of currents is zero, unless the circuits are unbalanced. In distributing on the three-phase system, a fourth wire can be employed, as it gives an advantage in the amount of copper used.

In all these alternating systems the great difficulty lies in the fact that the inductance of the circuit causes the current to lag behind the electromotive force. In the case of transmission to very long distances the line inductance is a large proportion of the total, while the inductance of the receiving apparatus depends upon whether lights or motors are to be supplied and upon the construction of the latter. The difficulty due to the uneven loading of the circuits is specially marked in the case of the three-phase system, and it is one of the principal objections that have been urged against the employment of this system for distribution. It should be pointed out, too, that it is not enough to balance the quantities of current for the three-branches of the system, but the character of the current must also be considered.

As for line inductance in the two-phase and three-phase systems, there is no question that the latter has an advantage in this respect. By suitable arrangement of circuits the line inductance can be brought to a minimum, and this is of the utmost importance in long distance transmission. I will not take into account the supposed increased efficiency of three phase motors and dynamos as against two-phase apparatus, as there is a question as to whether a superiority exists, but simply considering the decreased amount of copper required and the decreased inductance of the line, there is no question, in my mind, that for transmission, the three-phase system is superior to the two-phase. It is well known, of course, that the inductance of the circuit can be, in some measure, compensated for by the use of condensers or over-excited synchronous motors. The first of these remedies is, however, a very uncertain quantity commercially, while the second should be used as much as possible, that is, as many synchronous motors should be connected as is practicable. The best remedy, as things stand at present, lies in the careful construction of the line and the apparatus, so that the effects, although they exist, can be reduced to a minimum.

It has been shown by Mr. Scott, and others, that it is possible to transform a two-phase into a three-phase current, to transmit it and to transform it back again to a two-phase current. This will allow us, if we wish, to use two-phase dynamos for generating the current, to transmit with the advantage incidental to the use of three-phases, and at our reducing end to use two-phase circuits for transmission. This has some advantages as far as balancing the voltage on the circuit goes, and it has been proposed in the case of several plants whose installation is being considered.

Looking broadly at the value of alternating transmission as against continuous current transmission, we have a gain in the simplicity and safety in the transmission, and at the distributing end the use of multiphase currents enables us to supply both lamps and power with an economy and success comparable to that of the continuous current system. If it is necessary to use continuous currents for certain types of distribution at the receiving end, they can be obtained by the use of rotary transformers, by which the alternating current is transformed into a continuous current. These machines have approximately the efficiency of corresponding continuous current dynamos, while the output for a given size is about 50 per cent. greater.

MARRIED.

MEIKLEHAM—DASH.—The marriage took place on October 7 of Mr. T. D. R. Meikleham, of C. C. Sibley & Co., to Miss A. D. Dash, at the Church of the Mediator, Kingsbridge. New York City. The officiating clergyman was Dr. Morgan Dix, assisted by the Rev. Dr. McKee Brown and the Rev. George Nattress. Mr. W. A. Meikleham was his brother's best man.

STEERS—BEALES.—On Wednesday, October 7, 1896, at Clover Nook, Scarsdale, N. Y., Mr. James Rich Steers was married to Miss Mary Dolores Beales, daughter of Mrs. James A. G. Beales, and grand-daughter of the late Eugene Kelly. Owing to the illness of Mrs. Beales, the wedding ceremony was held at the home of the bride in a quiet manner, none but members of the family being present. Although a large number of friends and acquaintances had originally been invited, the cards were recalled some days ago. Mr. Steers has been connected with the electrical business for some years, starting with the Interior Conduit and Insulation Company, and now being the partner of Mr. A. K. Warren, trading under the name of A. K. Warren & Co. Mr. Steers has also the distinction of being a nephew of James Steers, the builder of the racing yacht America. He is a graduate of Columbia College.

OBITUARY.

HIPPOLYTE LOUIS FIZEAU.

The death is announced at the age of seventy-seven, of Fizeau, who devised the first method for the determination of the velocity of light by means of the revolution of a toothed wheel, placed between the observer and a distant reflecting mirror. Fizeau also made researches on the velocity of propagation of electricity. He was a member of the French Academy of Sciences, and made many contributions to the "Comptes Rendus" of that body.

SOCIETY AND CLUB NOTES.

NATIONAL ELECTRIC LIGHT ASSOCIATION.—PRESIDENT'S INTERIM RERORT NO. 2.

PRESIDENT Nicholls, of the National Electric Light Association, has just issued his second ad interim report, which is printed below:

I have to advise you that, since issuing my first interim report in August last, the officers and Executive Committee of the association have been actively engaged in endeavoring to promote the interests of the association and its members. There have been many services performed for individual members, which, being more or less of a private nature, are not set forth herein; this report dealing more directly with the public policy of the association and such other matters as may be of value to the electric lighting interests in general.

INCREASED MEMBERSHIP.—I am pleased to report that a number of new members have been added to the roll of the association within the past few weeks, and that the prospects are that, before our next convention, we will have a larger active membership than at any time previous; and our secretary, who has just returned from a visit to a number of central stations, reports that an active interest is being taken in the work of the associaion.

MUNICIPAL LIGHTING STATISTICS.—In August last we issued to members for confidential use, a preliminary report of the cost of arc lighting in the cities and towns of the United States, and promised a supplementary report at an early date. This supplementary report has been incorporated with the preliminary one, and the bulletin containing these statistics has been compiled with an end to handy reference, and is most complete. A copy is herewith inclosed.

REPORT OF COMMITTEE ON DATA.—The most important standing committee of the association has been the Committee on Data, and it has been a matter of regret that the self-sacrificing efforts of its able chairman, Mr. H. M. Swetland, have not heretofore met with the support to which they were entitled. The information for the guidance of the committee was sought to be obtained in the past by correspondence and the filling out of blank forms, but always with discouraging results.

This year, with the approval of the Executive Committee, a different course has been adopted. Mr. Swetland and myself have had several conferences regarding the matter and scope of the report for our next convention, and a practical engineer of high standing was retained to personally visit a number of central stations in the East and West, and gather from first hands the information we had decided upon as being necessary. I have this week carefully reviewed such portions of the report as have been completed, and can promise our members that it will, in my opinion, when completed, be the most valuable publication yet issued by the association. It will be printed in book form, and will, I hope, be ready for distribution on or about March 1, next, so that members may have ample time to prepare for its discussion at the convention.

CONSOLIDATION OF LIGHTING AND RAILWAY INTERESTS.—Whilst admitting that there is plenty of room for widely divergent views as to the benefit, or otherwise, to those interested in a consolidation of the National Electric Light Association and the American Street Railway Association, I considered that the present was an opportune time for the discussion of the subject, and wrote Mr. H. M. Littell, president of the latter association, suggesting a conference. A letter, of which the following is a copy, has been received from the secretary:

"Frederic Nicholls, Esq., President,
National Electric Light Association,
Toronto, Ont."

"Dear Sir: The following is an extract from the minutes of a special meeting of the Executive Committee of the American Street Railway Association, held in New York City, September 9 and 10, 1896.

"'A letter from Mr. Frederic Nicholls, of Toronto. Ont., president of the National Electric Light Association, relating to the matter of the consolidation of the two associations, was read; and the secretary was instructed to notify Mr. Nicholls that the Executive Committee would be willing to have Mr. Nicholls appoint three representatives of the National Electric Light Association, engaged exclusively in the lighting business, to confer with three representatives of the American Street Railway Association, engaged exclusively in the street railway business; and that those gentlemen consider the subject fully'"

"Yours truly,
(Signed) "T. C. PENNINGTON,
"Secretary and Treasurer."

I have appointed the following active members of our association, Mr. W. S. Barstow, Brooklyn, N. Y.; Mr. Henry Clay, Philadelphia, Pa.; Mr. Chas. E. Scott, Bristol, Pa., to confer with the three gentlemen to be appointed by the American Street Railway Association.

A LEGAL OPINION REGARDING THE RIGHTS OF LIGHTING COMPANIES TO USE OF STREETS FOR OVERHEAD WIRES.—The following request for information was recently published in a New York electrical journal:

"We are having trouble with house-movers cutting our wires, claiming that they have a right to the highway. Our attorney here does not find any law bearing directly on this trouble, and we wish to make them stop bothering us if the law is with us. Please cite us to where we will find cases of this kind decided; and any other information relating to same will be thankfully received.

"Yours respectfully,
"McPherson Water and Electric Company,
"J. E. WRIGHT, Manager.
"McPherson, Kas., September 15, 1896."

The correspondent was referred by the editor to the secretary of the National Electric Light Association as being the most likely source from which to procure the information desired. Although this is one of those questions usually considered private, and the information sent direct to the inquiring member, I have thought that an opinion on the rights of central station companies to the use of the streets for the purpose of stringing wires would be of interest to our members generally, and therefore submit herewith an opinion from Mr. Eugene H. Lewis, of the law firm of Messrs. Eaton & Lewis, of this city:

"Frederic Nicholls, Esq.,
"Toronto, Canada.

"Dear Sir: You have requested my opinion as to the rights of owners of electric light wires strung along the streets of a city as related to the rights of the owenrs of buildings to move them along the highway and to cut all wires interfering with their progress.

It is difficult to give a satisfactory answer to a question of this character that would be applicable to both cases, as different States have different rules of public policy, and in different States the statutes, municipal charters and grants differ so widely as to render each case independent of others and determinable only upon the facts specially pertaining to it.

My opinion in general is that the moving of a building along a highway is not one of the rights enjoyable by the general public in a public highway for the purpose of travel, and that if a person moves a building along or across a highway, he must do it with due regard to the rights of property enjoyed by those who are then using the highway for purposes of transmitting electricity for power or illumination. You will hardly expect me to give my reasons in detail for this view, and I will not do more within the limits of this letter than to refer you to a few cases which have come under my observation bearing upon this subject.

"New York & New Jersey Telephone Company vs. Dexheimer." (14, N. J. Law Journ., 295.)

"In that case telephone wires were stretched across the highway in pursuance of the act under which the company was incorporated and with the consent of the municipal authorities. There was a proviso in the charter that the wires should be so located as to in no way interfere with the safety or convenience of persons traveling on or over the roads or highways. There was a statute declaring that the use of a public street "in any of the incorporated cities or towns of this State, shall be subject to such regulations and restrictions as may be imposed by the corporate authorities of said cities or towns." The city of Orange had adopted an ordinance declaring that "all telegraphic and telephone wires shall be placed so as to hang not less than twenty feet above the street crossing." The defendant had a special license to move a house along a street, and in moving it he cut all the overhanging wires, and in an action by the telephone company it was insisted on the part of the plaintiff that thirty of these wires were more than twenty feet above the street. Judge Depue, of the New Jersey Supreme Court, charged the jury that the use of a public highway in moving a building was not within the right enjoyable by the public in a public highway for the purpose of travel, and that the defendant's act was not justified on the ground that he was obstructed in the use of the highway for public travel. He held, however, that since the defendant had a special license to move the house, the defendant was justified

in cutting such wires as were maintained in violation of the city ordinance less than twenty feet above the surface, and he left it to the jury to decide whether any of the wires that were cut were more than twenty feet above the roadway, and to assess damages for the cutting of these, and these alone.

"The case of 'Williams vs. Citizens' Street Railway Company' (8, St. Ry. Jour., 102) arose in the State of Indiana, and was decided by the Indiana Supreme Court in December, 1891.

"In that case it appears that a church congregation, with the tacit permission of the city council, sought to move its edifice across a street occupied by a line of street railway, operated by electricity, with the overhead wire system. The building being too high to pass under the wires, the contractor employed by the congregation threatened to cut the wires, relying upon the tacit permission of the city and upon the claim that the company had forfeited its right in the streets by changing its motive power without specific authority. In a suit by the company, to enjoin the threatened destruction of its property, the point was made by the defendants that the court had no jurisdiction to control the city council in the exercise of its authority over the streets. The court, very promptly and properly, decided that the authority to determine legal controversies concerning personal or property rights had not been vested in the common councils of the cities of that State; that the failure or refusal of the common council to take steps to prevent the injury or destruction of the railway property did not preclude the company from seeking redress in court; that no individual could insist that the corporate existence of the company had terminated, or that he could, at pleasure, confiscate or destroy its property in order to move a house across its tracks; and that, although citizens had the right to the ordinary use of the streets, they could not interrupt traffic or discommode the public by tearing down street car lines in order to remove buildings along the streets.

"In your own city of Toronto, there arose the case of 'Toronto Street Railway vs. Dollery' (112, Ont. App., 679), in which it was held that a person cannot lawfully blockade the tracks of a railway company by moving a building.

"It is true that as far back as 1852, in the case of 'Telegraph Company vs. Wilt' (11, Am. Law Journ., 374), it was held that legislative authority and municipal license to set up a telegraph line in the street, were no defense in an action for injury to a house being moved along the street and caught by the wires. But that case does not seem to have been well considered, nor has it been generally followed by the courts, and it is expressly disapproved by Scott & Jarnagin in their works on telegraphs, section 53.

"I have not had time since receiving your request to search the decisions of the past three years relating to this subject, but, in my opinion, the foregoing cases in New Jersey and Indiana are much more likely to be followed than the case last referred to.

"I hope that the views expressed in these few lines will avail you for your purpose.

"Yours truly,

(Signed) "EUGENE H. LEWIS."

STANDARDIZATION OF INCANDESCENT LAMP SOCKET AND BASE.—The question of a standard incandescent lamp socket and lamp base has frequently been discussed in an informal way at meetings of the association, but no effort made to bring together those most directly interested.

Believing that much might be accomplished by holding a meeting under neutral auspices, I wrote to the manufacturers of sockets and lamps, inquiring if they would be willing to attend a meeting to discuss ways and means of endeavoring to solve this difficult problem, if such were called by the association. The replies received were unanimous in their expressed desire to be present at a meeting to be called by the association for such a purpose, and I therefore, on the 24th ult., issued the following notice of meeting. (Here follows the notice.)

Whilst I am doubtful of any direct result towards the desired end from this first meeting, I am hopeful that we can enter the thin end of the wedge at least, and by sustained and persistent effort accomplish what we have in view.

In conclusion, I have to request that members will promptly communicate with our secretary on any subject that properly pertains to the business of the association, and regarding which they may desire information or action.

THE AMERICAN INSTITUTE FAIR.

The American Institute Fair, which is in progress at the Madison Square Garden, New York, brings again the favorite exhibition with all its vigor and variety of exhibits which the Institute may well be proud of. With working machinery on the main floor and machinery downstairs and a splendid exhibit of flowers, fruits and vegetables in the concert hall there is so much for 25 cents' admission that no one can be disappointed who visits the Madison Square Garden. The music every afternoon and evening is a prominent feature, and, taken all in all, there is something for everybody to see and much for everybody to enjoy. The display in the concert hall will be kept complete until October 24, under the administration of the Committee on Agriculture and Horticulture and the Farmers' Club.

STANDARDIZING INCANDESCENT LAMP SOCKETS AND BASES.—MEETING OF MANUFACTURERS.

PURSUANT to a call of President Frederic Nicholls, of the National Electric Light Association, a representative body of incandescent lamp manufacturers met at the rooms of the American Institute of Electrical Engineers on October 9 for the purpose of devising ways and means to bring about the adoption of a standard socket and lamp base.

Mr. Nicholls, in opening the meeting, spoke as follows:

"In order that there may be no misunderstanding in regard to the attitude of the National Electric Light Association, I take the opportunity of stating before the business of the meeting commences that on behalf of the association I have endeavored to bring together the several interests here represented for the purpose of discussing the question at issue, and of trying to solve the somewhat difficult problem of standardizing the incandescent lamp socket and lamp base. This association is absolutely impartial, and it was thought that more could be accomplished by holding such a meeting under neutral auspices than in any other way. The object of the association in bringing together such a representative gathering now having been attained, it becomes your duty to elect a chairman."

On motion, Mr. Nicholls was requested to act as chairman, and Mr. Geo. F. Porter as secretary.

Mr. F. S. Terry then moved the following resolution; seconded by Mr. Hills.

"That it is the opinion of those present at this meeting that a standard lamp socket and lamp base is desirable." This was carried.

A long general discussion then ensued, nearly every gentleman present taking part, and many facts of interest were brought out, and seeming difficulties were debated as they arose.

The final results of the meeting are set forth in the following resolutions, which in each case were carried unanimously, it being understood that another general meeting is to be called to receive the report of the committee appointed.

Resolution moved by Mr. Ries, seconded by Mr. Rockwell:

"That before proceeding to investigate the patent situation or licensee question, to obtain the opinion of this meeting as to whether any existing type of socket or lamp base fulfills all the requirements that a standard socket should possess."

Resolution moved by Mr. Terry, seconded by Mr. Bryant:

"That the most desirable lamp base and socket, in itself considered, is a socket adapted for Edison base lamps."

"Resolved, That a committee composed of Mr. Terry, Mr. Rockwell, Mr. Bryant and Mr. Hills, be appointed to confer with the licensers and licensees of the socket patents with a view to arranging for their general use, and to report back to a meeting at an early date, and that the president of the National Electric Light Association be requested to act as chairman."

Among those present were the following: Frederic Nicholls, President National Electric Light Association; Geo. F. Porter, secretary, N. E. L. A.; Chas. I. Hills, Perkins Electric Switch Manufacturing Company; W. C. Bryant, Bryant Electric Company; C. E. Scott, Bristol Electric Light Company, Bristol, Pa.; A. A. Pope, Edison Electric Illuminating Company, New York; A. D. Page, Harrison Lamp Works, Harrison, N. J.; M. K. Eyre, General Electric Company; F. W. Hawkins, Electrical Engineering and Supply Company; A. B. Field, Anchor Electric Company; C. H. Rockwell, Buckeye Electric Company; F. S. Terry, Sunbeam Incandescent Lamp Company; C. D. Marsh, Bryan-Marsh Company; A. P. Seymour, Pass & Seymour, S. Wheelwright, John E. Criggal, Newark, N. J.; H. C. Wirt, General Electric Company; E. E. Ries, New York; W. F. Hanks, "The Electrical Engineer"; C. W. Price, "Electrical Review"; W. J. Johnston, and J. B. Taltavall, "Electrical World."

NEW YORK ELECTRICAL SOCIETY.

The society is to hold its first meeting for the season, on October 13, at 8 p. m., at Columbia University, Madison avenue and Forty-ninth street, when President Emery delivers an inaugural address entitled: "Reminiscences of Forty Years of Engineering Experience." Dr. Emery has rich resources to draw upon, and we have no doubt that his address which will have been delivered by this time will charm and instruct a large gathering of the members.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The next meeting of the Institute will be held at 12 West Thirty-first street on Wednesday evening, October 21, and will be devoted to a topical discussion on the subject of "Electric Traction Under Steam Railway Conditions." The discussion will be opened by Dr. Charles E. Emery, and prominent steam engineers as well as electrical engineers have accepted invitations to participate. Arrangements are being made for a similar meeting to be held at Chicago the same evening.

THE SPECIAL TRAIN from New York for the street railway convention at St. Louis, is to leave on Saturday instead ot Sunday, owing to the desire of many to be in St. Louis throughout Monday preparing their exhibits, etc.

DR. MARGARET A. CLEAVES, director, has issued an interesting report on the work for the year at the New York Electro-Therapeutic Clinic, Laboratory and Dispensary.

VEREINIGTE ELECTRICITAETS ACTIENGESELLSCHAFT OF VIENNA.

The firm of B. Egger & Company, of Vienna and Budapest, has been incorporated into a stock company with the above title. This is one of the oldest electrical firms in Austria and among the first to take up electric lighting and power work. Mr. Ernst Egger, who spent several years in this country studying American methods of manufacture, is chief engineer of the company. Both he and the company have our best wishes for their future.

EDUCATIONAL.

Y. M. C. A. STEAM ENGINEERING CLASS.

The steam engineering class of the Young Men's Institute, 222-224 Bowery, this city, opened its 1896-97 session on the evening of October 7, and will continue open Wednesday and Friday evenings of each week until April 29, 1897. The class is in charge of Mr. William H. Weightman, as usual.

Its object is the instruction of all employed or expecting to be employed in the practical operation of engines, boilers and machinery, and desirous of gaining a knowledge of or improving themselves in the theoretical branches, rules and practice of steam engine, boiler and power transmission calculations. Those desirous of availing themselves of the opportunity should join at once.

NEWS AND NOTES.

THE CHICAGO GREAT SOUND MONEY PARADE.

THAT the great parade which took place in Chicago on Friday, the 9th instant, was a truly magnificent pageant, goes without saying. All the trades in the city turned out in their strength determined to do their utmost to show that the great majority of their representatives thoroughly believed in the sound money standard, and were averse to any blind experimenting. Amongst the representative trades which took part in this splendid display the electrical industries had a most prominent place. Several meetings were held, having been originally called by Messrs. B. E. Sunny, C. E. Gregory and J. F. Gilchrist. A branch association was also established with F. E. Drake, president; C. T. Gage, secretary, and B. E. Sunny, treasurer. There were also other committees appointed, the principal one having representative men of every branch of the electrical industry to take charge of some particular duties, and be able to show what could be done by those engaged in this great industry on such an occasion. The electrical division, which mustered some 1,500 strong, formed at Haymarket Square, and joined with the steel and ironworkers, who composed the principal part of the second division.

Mr. F. B. Badt, who was appointed marshal, was unfortunately prevented from filling that office through sickness, and his place was taken by Mr. H. F. J. Porter. The electrical division was headed by one of the American Electrical Vehicle Co.'s electric carriages, and also by a banner, on which was inscribed, "Youngest industry in the line," "One thousand millions represented." Then came the squadrons of the various electrical industries of the city, including the Western Electric Co., 350 men, with banner, badges and gold canes; telegraphers, 350 men; Chicago Edison Co., 350 men, band, banner, gold badges, gold hats, gold umbrellas and white gloves; Chicago Telephone Co., 200 men; General Electric Co., 60 men, torch sticks, with incandescent lamp head, and decorated with bows of national colors, also banners with appropriate electrical terms, as applied to the present campaign; Electric Appliance Co., 35 men, full uniform, gold derby hats, gold capes, gold shoes, dark trousers, with gold stripe, and also an effective equipment of electrical apparatus. This company was drilled and officered under United States tactics, with drum corps. Central Electric Co., 32 men, gold sticks and several banners adorned with incandescent lamps and colored bows, and amusing inscriptions, which were apropos to the occasion, such as "The cat came back, and so will prosperity;" "Central Electric Co. for sound money;" "100 cents make a dollar," "Okonite, it never disappoints," and others. The remaining part of the electrical division, consisting of about 190 men, included electrical engineers, electrical contractors, and some who had had no special places assigned to them.

Another most important feature of the electrical division of the parade was the connection by long-distance telephone of several cities, East and West, with Chicago. Two large banners were placed at the Telephone Building and Great Northern Hotel, on which was the sentiment, "Your cheers at this point will resound throughout the union." At the former place were several large transmitters to convey the shouts of applause to the distant listeners, and there were also additional transmitters at the Great Northern Hotel and other points along the line of march. These cheers were heard in New York and other cities and by the Republican candidates.

MORSE RELAY SIGNALING BY MEANS OF HERTZIAN WAVES.

At the recent meeting of the British Association, Mr. W. H. Preece stated in the course of the discussion on Prof. Chunder Bose's paper on "Electric Wave Apparatus," that a young Italian, Signor Marconi, had described experiments in which he had, by means of Hertzian waves, transmitted signals over a considerable distance, and as a result Mr. Preece had assisted Signor Marconi to continue his experiments in London and on Salisbury Plain. Signor Marconi has now succeeded in producing electric waves and reflecting them from one parabolic mirror to another one and a-quarter mile distant, the waves falling on a receiving apparatus, which actuated a relay and produced Morse signals; the experiments have been made with crude apparatus and without employing any great amount of radiant energy.

MOISSAN'S EXPERIMENTS WITH THE ELECTRIC FURNACE.

In the current number of the "Annales de Chim. et de Phys.," M. Moissan, says "Nature," gives an interesting account of the experiments on the volatilization of refractory substances in the electric furnace. The sublimates were condensed on the outside of a curved copper tube placed two centimetres below the arc, and just above the substance under examination. A rapid current of water was passed through the tube, and kept it cool during the experiments, which usually lasted for about five minutes. The volatilized metals were copper, silver, platinum, aluminum, tin, gold, manganese, iron and uranium. Quantitative experiments were not made in every case, but it appeared that manganese was sublimed more rapidly than the others, and that the rate of volatilization of copper was about five times as rapid as that of gold. The condensed metal was usually, in great part, in the form of little spheres. Silicon and carbon were also volatilized and condensed on the tube, though the amount collected of the last named element was very small, and lime, magnesia, zirconia, and silica were sublimed without difficulty. M. Moissan draws the conclusion that the most stable compounds hitherto known disappear in the electric furnace, being either decomposed or volatilized. Nothing resists these high temperatures except the series of perfectly crystallized compounds discovered by him, and consisting of borides, silicides and, above all, carbides of the metals. M. Moissan intends to publish a description of these compounds shortly. He regards them as being probably among the original constituents of the globe, and as still existing in some of the stars.

PROF. ROENTGEN has received a copy of the Thompson & Anthony book on X-rays, and writes that he has read it with great interest.

"I do not want to miss a single number of The Engineer. Each number is a treat and is thoroughly appreciated."—B. Quinn.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Electro-Chemistry:

AN ELECTRIC FURNACE FOR IRON AND STEEL.—By R. Urbanitzky. A furnace suitable for preparing pure iron, which must subsequently be carbonized, is described in "Zeitschr. für Elektrochemie," vol. ii, p. 350.

Measurements:

TESLA'S ELECTRICAL CONDENSER.—Description of this instrument, for which patent was issued Sept. 15, 1896.—"Elec. Rev.," Sept. 23, 1896.

Miscellaneous:

ELECTRIC FARMING.—A few results obtained at the Agricultural Department of Cornell University and by Mr. Rawson, a farmer near Boston, are recorded in "Scientific American," Sept. 26, 1896.

FORT WAYNE ELECTRIC CORPORATION.—An extended, well illustrated description of the electrical apparatus of this company.—"Elec. World," Oct. 3, 1896.

Power Transmission:

GAS VERSUS ELECTRICITY IN POWER TRANSMISSION.—By Nelson W. Perry. Author compares the transmission of electricity with other methods, namely with water, coal and gas. The latter he finds to be an exceedingly economical method.—"Engineering Magazine," Oct., 1896.

ELECTRICAL ENERGY AT TOULOUSE.—A water power plant. Each turbine controls two dynamos which are run together to give the three-wire distribution. The tariff of charges is as follows:

Lamp of 10 candle power per month	....	$.70
" 16 " "	....	1.10
" 20 " "	....	1.30
" 30 " "	....	1.80

For arc lamps of four amperes or above one dollar per ampere per month is charged. For motors $1.20 per horse-power per annum is charged for 10 hours a day.—"Western Elec.," Sept. 26, '96.

TESTS OF POWER ABSORBED BY ELECTRICALLY DRIVEN MACHINE TOOLS.—By C. W. Pike. These tests were made at the Baldwin Locomotive Works and include the following: Three-spindle drilling machine, two-spindle drilling machine, radial drilling machine, several planers, slotting machine, double head locomotive frame slotting machine and shaping machine.—"Am. Machinist," Sept. 24, '96.

Railways:

WILLOW GROVE PARK AND ELECTRIC ROAD.—By Hermann S. Hering. A description of this pleasure park and of the road leading to it. Several maps, charts and tables. The article is begun in "Elec. World," Oct. 3, 1896, and is to be continued in subsequent issues.

LONG DISTANCE AND HEAVY DUTY ELECTRIC RAILWAYS.—By F. W. Darlington. Paper read before the Penn. Str. R'way Assoc., Altoona, Pa., Sept. 2, 1896. Author points out the many advantages of the electric systems, believes in the value of the direct current. He also discusses the questions of grading, curves, trucks, etc.—"Elec. Engr.", Sept. 9, 1896.

INSPECTION AND CARE OF CAR EQUIPMENTS.—By J. B. Cahoon. Paper read before the Str. R'way Convention at Binghamton, Sept. 8, '96. Speaker suggested the desirability of trip inspections, daily and monthly inspections.—"Elec. Engr.," Sept. 23, '96.

STREET RAILWAY TRUCK CONSTRUCTION AND MAINTENANCE.—By Geo. Neilson. Paper read before the Penn. Str. R'way Convention, Sept. 2, '96. First: No arbitrary specification should be made, regarding foundation, but should be built in accordance with desirability as one goes along. Second: Concrete mixture described. Third: Ties should be 6 inches on face, 7 feet 6 inches long and of white or rock oak and thoroughly seasoned. Fourth: At least 70 lb rails should be used. Fifth: Splices, frogs, grading, wagon traffic form other points of discussion.—"Elec. Rev.," Sept. 23, '96.

USE OF OLD RAILS AS UNDERGROUND CONDUCTORS.—By F. O. Rusling. Paper read before the N. Y. Str. R'way Assoc. at Binghamton, Sept. 8, 1896. Author stated a case where old rails were used practically four in multiple to convey the grounded current back to the station.—"Elec. Engr.," Sept. 23, 1896.

RAILWAYS OF THE WORLD.—In an editorial note the existing mileage of railway is given thus: Europe, 152,422; North America, 203,138; South America, 23,799; Asia, 26,078; Africa, 8,141; Australia, 13,795.—"Age of Steel," Sept. 19, '96.

TROLLEY LINES BETWEEN LAKES ERIE AND ONTARIO.—By Orrin E. Dunlap. The process of constructing this road is novel in several respects.—"Western Elec.," Sept. 26, '96.

Roentgen Rays:

REVIEW OF THE SUBJECT TO DATE.—By Prof. J. J. Thomson. Opening address before the Mathematical and Physical Section of the British Association for the Advancement of Science.—"Electricity," Sept. 23, 1896.

ROENTGEN RAY TUBES.—By W. M. Stine. A contribution on the various tubes in vogue, with a statement of the why and wherefore of special shapes of tubes, anodes and cathodes.—"Elec. World," Oct. 3, 1896.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED OCT. 6, 1896.

Alarms and Signals:—

NIGHT SIGNALING. R. O. Crowley, Elizabeth, N. J., 568,838. Filed Dec. 12, 1895.

Signaling apparatus employing suitably controlled lights behind colored glass, whereby signals made up of different colored flashes can be made.

STATION OR STREET INDICATOR. E. B. and W. R. Lodge, Cuyahoga Falls, N. Y., 568,859. Filed June 15, 1896.

A roller displaying the names of streets to be passed and means for employing a shunt current from the overhead conductor to rotate the roller at predetermined points. The circuit is closed by a projecting arm at street corners.

LOCK-AND-BLOCK SIGNALING ON RAILWAYS. W. R. Sykes, Jr., and J. P. O'Donnell, of London, England, 568,993. Filed Feb. 6, 1895.

Details of construction.

Switches, Cut-Outs, Etc:—

INSULATED ELECTRIC CABLE. M. Guilleaume, Mulheim-on-Rhine, Germany, 568,756. Filed Nov. 25, 1895.

The insulating material is arranged inside and outside alternate convolutions of windings of fibrous material.

ELECTRIC CABLE. S. P. Thompson, London, England, 568,964. Filed Dec. 19, 1893.

The combination with a single conductor electric cable for submarine use of compensating branches, consisting of an insulated conductor having both a higher resistance and a higher self-induction than the entire length of the main conductor jointed into the cable at some intermediate point and constituting an integral part of the cable.

Dynamos and Motors:—

OSCILLATING RECIPROCATING TRIPOLAR ELECTRIC MOTOR. T. H. Hicks, Detroit, Mich., 568,947. Filed Dec. 19, 1892.

The combination of a solenoid and a magnet, journaled in bearings so as to oscillate together.

Electro-Metallurgy:—

APPARATUS FOR THE ELECTRODEPOSITION OF GOLD OR SILVER. E. Andreoli, London, England, 568,724. Filed July 10, 1895.

Comprises a solution, a tank provided with anodes and a series of amalgamated cathodes, consisting of perforated plates and a layer of mercury in the bottom of the tank into which each of the cathodes dip.

PROCESS OF EXTRACTING GOLD FROM SUBSTANCES CONTAINING IT. H. R. Cassel, New York, 568,741. Filed Feb. 9, 1895.

Employs bromin solutions and regenerates the solution.

PROCESS OF TREATING METALLIC SULFIDS. V. Engelhardt and D. Nettel, Vienna, Austria-Hungary, 568,843. Filed April 20, 1896.

The sulfid is first treated with a reagent consisting of sulfhydrate of the alkalies in aqueous solution and is then decomposed by electrolysis.

Lamps and Appurtenances:—

ELECTRIC SLIDE FOR CHANDELIERS. G. J. Carson, Chicago, Ill., 568,740. Filed Oct. 23, 1895.

Comprises a tube having on its inner surface electric conductors insulated from the rod, but exposed interiorly, and electric connection with the conductors by means of a rod located in the tube.

ELECTRIC ARC LAMP.—R. Scheefbauer, Hoboken, N. J., 568,798. Filed Sept. 24, 1895.

The carbon holders are fitted to slide upon hanging tubes.

ELECTRIC ARC LAMP. N. G. Meade, Jamestown, N. Y., 568,861. Filed May 15, 1896.

Directly operated by the electric current acting upon an electromagnet.

SOCKET FOR INCANDESCENT ELECTRIC LAMPS. J. Pass and A. P. Seymour, New York, 568,919. Filed Feb. 14, 1896.

Porcelain socket. Details of construction.

Miscellaneous:—

MEANS FOR GENERATING ELECTRIC WAVES OR OSCILLATIONS. D. McF. Moore, Newark, N. J., 568,863. Filed Dec. 7, 1895.

Consists in momentarily interrupting in succession a series of induction circuits turning the electric vibrations thus produced in each interruption into a working circuit common to the induction cir-

cuits, and in the intervals between interruptions of each circuit and during the operation of other circuits, connecting each circuit to the source of electric energy. Uses a rotary interrupter.

ELECTRIC MINING MACHINE. R. H. Wiles, Freeport, Ill., 568,-833. Filed May 22, 1896.

The combination with a suitable carriage, of devices arranged thereon to cut a kerf into which the carriage may advance, means for forcing the carriage into the kerf so cut, and a wheel revolubly mounted upon the carriage and arranged to bite into one, only, of the kerf's broader walls, as the carriage is forced forward.

ELECTRIC CLOCK STRIKING MECHANISM. F. E. Girod, Geneva, Switzerland, 569,099. Filed Oct. 11, 1895.

Details of construction.

ELECTRICAL GAS REACTION APPARATUS. A. A. Naville and P. A and C. E. Guye, Geneva, Switzerland, 569,122. Filed Feb. 4, 1896.

Comprises independent aligned tubular electrodes, a tubular collector, insulating tubes connecting the tubular electrodes with the collector, and connections between the electrodes and a suitable source of electricity.

Railways and Appliances:—

ELECTRIC LOCOMOTIVE. J. E. Lockwood, Detroit, Mich., 568,-779. Filed June 10, 1893.

Embodies a supplemental frame supporting the motor gearing, the castings at the sides of the frame connected with the truck frame, the supporting springs and the motor mounted on the frame.

ELECTRIC MOTOR TRUCK. N. C. Bassett, Lynn, Mass., 568,891. Filed March 20, 1891.

Comprises elastically supported motor carrying bars, and an electric motor pivoted thereto in substantially the center of gravity of the machine and geared to the driven axle.

RAIL BOND. H. S. Newton, Syracuse, N. Y., 568,918. Filed Aug. 10, 1896.

Consists of a soft copper bond wire to the end of which are attached metallic end pieces, and means for securing them to the rail.

AUTOMATIC ELECTROMAGNETIC BRAKE FOR RAILWAY CARS. E. A. Hauerwas, Saratoga Springs, N. Y., 569,101. Filed May 23, 1895.

Comprises electromagnetic brakes adapted to engage with a track between the wheels of a truck upon closing a circuit.

Switches, Cut-Outs, Etc:—

SWITCH FOR ELECTRIC HEATING DEVICES. J. E. Meek, New York, and F. L. Powers, Brooklyn, N. Y., 568,783. Filed May 13, 1895.

Obviates the use of a rheostat.

MULTIFUSE CUT-OUT. W. Ehrhardt, Union, N. J., 568,971. Filed Dec. 23, 1895.

Fresh strips can be put on the cut-out to replace burned out or damaged ones without turning off the current or taking the cut-out cylinder from its support.

Telephones:—

TELEPHONE SWITCHBOARD. L. W. Davis, Mineral, W. Va., 568,840. Filed Dec. 5 1895.

Embodies an arrangement whereby all the lines will be always in communication with each other, or with the call bell of the central office.

TELEPHONE. A. Gartnerm, Newark, N. J., 569,018. Filed Feb. 15, 1896.

Embodies a series of balls arranged in the receiver and forming an annular bearing for one side of the diaphragm, and an annular curved flange forming the bearing for the other side of the diaphragm.

REPORTS OF COMPANIES.

A RECEIVER FOR THE E. S. GREELEY & CO.

It is with much regret that we note the collapse of another famous old concern under the pressure of the hard times and bad business, no less a pillar in the elctrical supply trade than The E. S. Greeley & Co. Last week upon application to Judge Lacombe in the U. S. Circuit Court, Gen. E. S. Greeley, president, and J. W. Sands, secretary, were appointed receivers for the concern. The business was established forty years ago by L. G. Tillotson & Company. Gen. Greeley became a partner in that firm in 1865, and in 1884 succeeded to the business after the death of Mr. Tillotson. The firm style was changed to The E. S. Greeley & Company, and the business was incorporated in 1887, under Connecticut laws, with a capital stock of $250,000. The liabilities are $160,000, of which $65,000 is for merchandise and $70,000 due on notes. The assets are $180,600.

LEGAL NOTES.

MR. A. J. DeCAMP'S RIGHT TO BE COUNCILMAN IN PHILADELPHIA.

The prominence of Mr. A. J. De Camp in electric lighting circles renders of interest a decision handed down at Pittsburg by the Supreme Court on October 5 in the case of the Commonwealth of Pennsylvania against A. J. De Camp, appeal from a judgment of ouster.

In 1894, while Mr. de Camp held stock in the Brush Electric Light Company, it entered into a contract for street lighting with the city of Philadelphia. Mr. De Camp was the company's secretary. In February, 1895, he was elected common councilman. The plaintiff claimed he had no right to assume the office. He demurred, but a judgment of ouster was ordered and he was enjoined.

Justice Sterrett says: "When he entered upon the discharge of his duties as Councilman he was interested as an officer and stockholder of the Brush Electric Light Co. in the contract which it had made with the city. Under the facts the court was fully justified in ousting him and, therefore, affirms the judgment."

PERSONAL.

MR. CHARLES A. GRANT. The directors of the Erie Telegraph and Telephone Company have elected Mr. Charles A. Grant treasurer of the corporation, to succeed Mr. Charles J. Glidden, who was recently chosen vice-president. Mr. Grant has been in the service of the company as general cashier and assistant treasurer for nearly fourteen years, and he has a large circle of friends who are well pleased with his advancement.

ANOTHER SET OF UNDERGROUND RAILWAY PLANS FOR NEW YORK.

The Underground Railroad Company of New York City has been incorporated with the Secretary of State. The new company is a consolidation of the Central Tunnel Railway Company, the New York and New Jersey Tunnel Company and the Terminal Underground Railroad Company. The company is organized with a capital stock of $5,000,000, and the directors are Charles C. Vost, of Ridgewood, N. J.; G. A. Liebig, of Brooklyn; Bernard F. O'Connor, Cornelius V. Sidell, Spencer Schuyler, Arthur M. Hatch, William C. Nickoll, James M. Fisk and Raymond L. Ward, of New York City.

According to the papers filed the company will construct an underground railroad in New York City which will be approximately five miles in length. The proposed line of the new road is: Beginning at the City Hall, running northerly to Chambers street, under Reade Street to Elm, northerly under Elm to and under Spring street and Marion or Mulberry streets to and under Great Jones street, northerly under Lafayette place to and under Astor place and Eighth street, northerly under Ninth street to Fourth avenue, northerly through and under Fourth avenue to and under Forty-second street, to the Grand Central Depot, connecting with the Fourth Avenue Improvement Co.

There will be three connecting branches with the main line. One at Thirty-third street, which will run to the East River, connecting with the Thirty-fourth street ferry; a second, beginning at the City Hall Park, running to the East River and southerly along the East River to South Ferry street, and the third starting from the City Hall Park and going to West street and following West street to South Ferry street. It is well understod that the company proposes to use electric traction.

RECENT CONTRIBUTION TO ROENTGEN RAY LITERATURE.

Papers on X-rays still form the staple article of the foreign scientific press. Useful abstracts of these are found both in Wiedemann's "Beiblätter" (No. 8) and in the Physical Society. The latter for September mentions that Messrs. Novák and Sulc have found absorption to increase with the number of atoms in the molecule, and with their atomic weights. Fluorine has an exceptionally high absorption, and bones owe their opacity mainly to fluoride of calcium.——C. Doelter has found that the absorption of X-rays is often anomalous; rock salt, sulphur, potash nitre, and realgar are opaque, considering their lightness; cryolite, corundum and diamond, though heavier, are perfectly transparent. He finds, in contradiction to the last author, that chemical constitution affords no guide, and the direction of the crystallographic axes is also without influence. He proposes a scale of transparency for these rays, consisting of diamond as the most transparent, corundum, talc, quartz, rock salt, calcspar, cerussite, and realgar as the most opaque.——Messrs. Eder and Valenta have failed to shorten exposures by using orthochromatic plates, but have shortened it by heating to 50° C., or by a screen of fluoride of calcium, used with a silver-bromide and celluloid film.——Among the "Beiblätter" abstracts, we find an account of Grunmach's success in discovering phthisis colonies in the lungs of a young man by means of a fluorescent screen, which also was capable of revealing arteriosclerosis of the aorta. M. Levy, in addition, observed the working of the stomach and the heart, which is the most opaque of the internal organs. G. Brandes found that X-rays could be seen if the crystalline lens were removed from the eye. All the humors of the eye are more or less opaque to them.—London "Electrician."

Trade Notes and Novelties

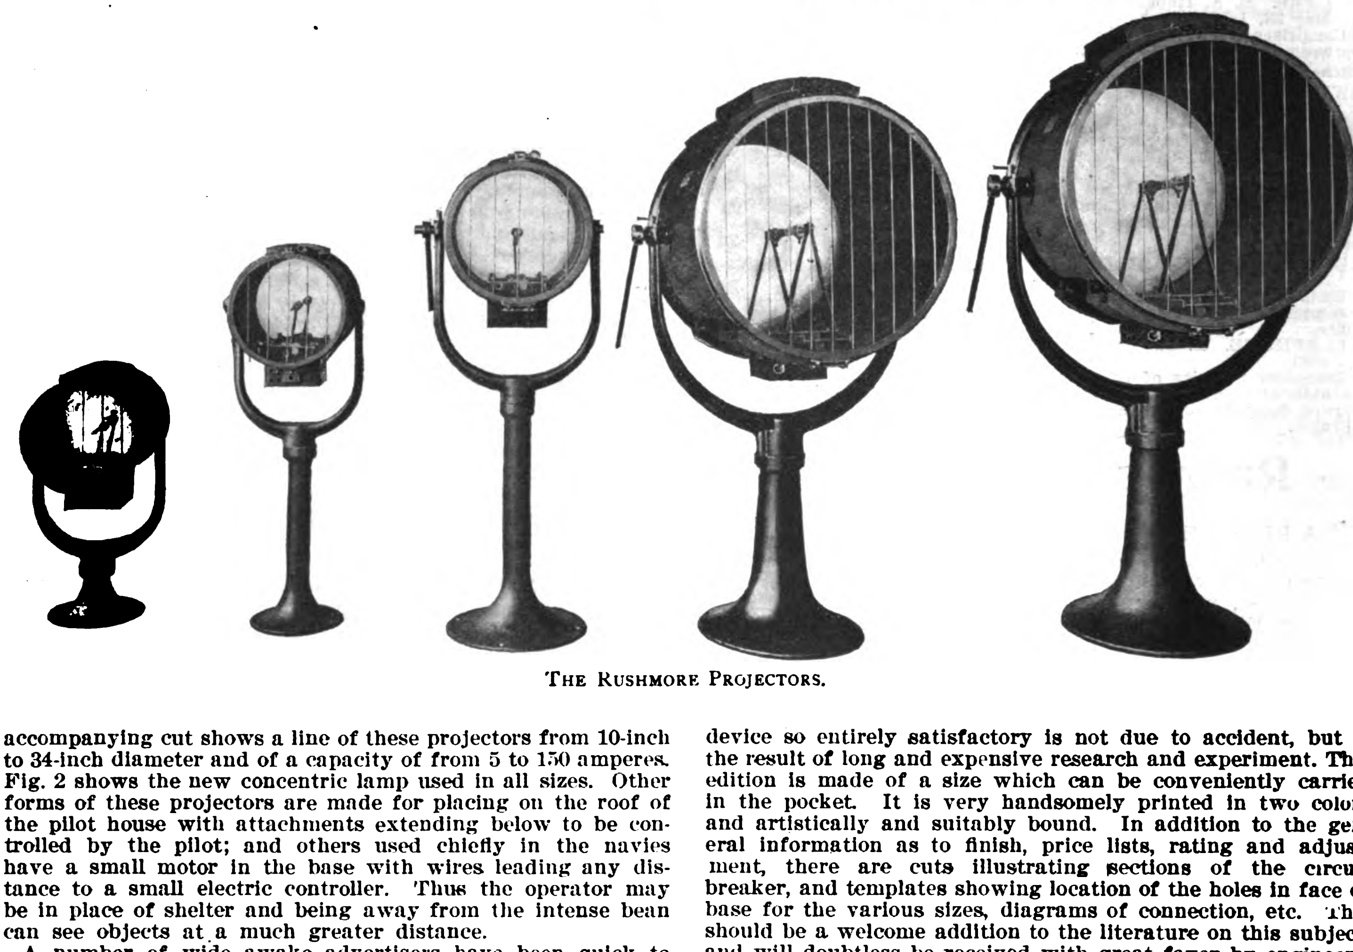
AND MECHANICAL DEPARTMENT.

RUSHMORE PROJECTORS.

OWING to the enormous cost of lenses as made by the old methods there were, it is said, no real searchlights used up to the present year except in the Navies and further, the mechanism employed heretofore has been so complicated and delicate as to render it impractical for use in commercial work.

Early realizing that there was a good demand for a cheap and perfect searchlight, Mr. .. W. Rushmore, who was one of the first in this field, has made a study of the subject, and after long experimenting succeeded in producing the special glass castings required. He has also perfected a machine for their finishing that brought the cost to but a fraction of that by the old methods. He also perfected a lamp mechanism that while containing fewer parts than the common street lamp will feed the heavy carbons toward or away from each other and hold the arc within one volt variation. This is the only arc lamp in use that feeds the carbons in both directions while containing no motors or contact devices of any kind.

This lamp with the new lens mirror, mounted in a sheet metal cylinder, forms the modern high power projector as made by the Rushmore Dynamo Works, of Jersey City. The accompanying cut shows a line of these projectors from 10-inch to 34-inch diameter and of a capacity of from 5 to 150 amperes. Fig. 2 shows the new concentric lamp used in all sizes. Other forms of these projectors are made for placing on the roof of the pilot house with attachments extending below to be controlled by the pilot; and others used chiefly in the navies have a small motor in the base with wires leading any distance to a small electric controller. Thus the operator may be in place of shelter and being away from the intense bean can see objects at a much greater distance.



THE RUSHMORE PROJECTORS.

A number of wide awake advertisers have been quick to appreciate the value of these lights and a number of tall buildings in the large cities are already equipped with powerful lights that throw their rays for miles around and attract the attention of all who may be out of doors. One of these 34-inch projectors is mounted on the lofty tower of the great New York department store of the Siegel-Cooper Company, which burns every night and is said to be clearly visible over 80 miles away.

THE SHOENBERGER STEEL COMPANY, Pittsburg, Pa., have awarded contracts to the Ball Engine Company, Erie, Pa., and Siemens-Halske Electric Company, New York, for a complete electric power plant, consisting of one 400 and one 150 horse-power vertical compound engine, direct connected to 225 kilowatt and 100 kilowatt generators.

EDISON X-RAY APPARATUS.

The Edison Manufacturing Co. are now placing on the market a complete line of Mr. Edison's X-ray apparatus. They are prepared to supply a range of outfits operated by battery power, and also the special high speed break wheel equipment, operated by the Edison current, as exhibited by Mr. Edison at the recent electrical show in this city. No genuine Edison apparatus has up to the present time been sold, as Mr. Edison has wished to bring the appliances to a high degree of perfection before allowing them to be placed on the market.

The Edison Laboratory now has a staff of men employed in making Edison X-ray focus tubes, all of which are manufactured under Mr. Edison's personal supervision.

THE CUTTER CIRCUIT BREAKER CATALOGUE.

The Cutter Electrical and Manufacturing Co. announce a new edition of their "Circuit Breaker Catalogue," complete and accurate as to price and data to October 1. This edition will be known as the "Engineers' Edition." The Cutter Company have been led to bring out a new catalogue by the success which attended the former edition, published in May last. They do so with a hope of giving information as to the scope of their work in this important and, until recently, much neglected field. The protection of circuits carrying heavy currents is a subject of first importance to users of electricity, and the fact that this company has been able to produce a device so entirely satisfactory is not due to accident, but is the result of long and expensive research and experiment. This edition is made of a size which can be conveniently carried in the pocket. It is very handsomely printed in two colors and artistically and suitably bound. In addition to the general information as to finish, price lists, rating and adjustment, there are cuts illustrating sections of the circuit breaker, and templates showing location of the holes in face of base for the various sizes, diagrams of connection, etc. This should be a welcome addition to the literature on this subject, and will doubtless be received with great favor by engineers, for whom it is especially intended.

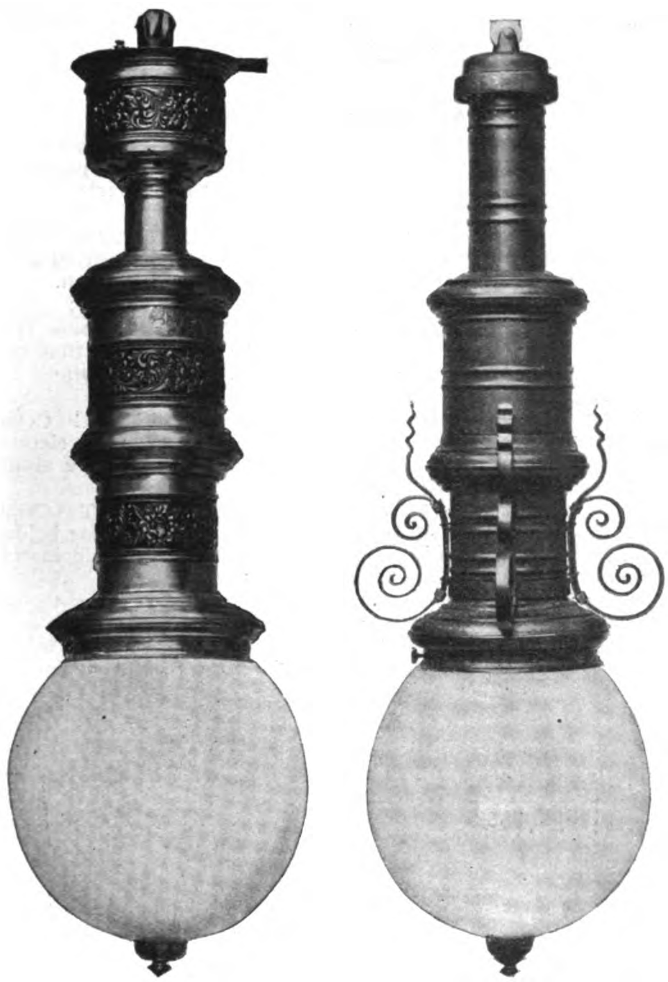
A few pages are devoted to the important details of the well-known C. S. switch, so that the possessor of this catalogue has at hand for immediate reference a concise description of the output of the Cutter factory, well known, as it is, for producing work which is electrically and mechanically of the highest standard of excellence. This catalogue will be sent on application.

THE GEORGE B. INMAN CONTRACT CAMPANY has been formed in this city under the laws of New York, with a capital stock of $10,000, and with G. B. Inman, E. L. Hunt and G. Froh, as directors. The object is to contract for the construction of waterworks, gas and electric light plants and electric railroads.

NEW STYLES OF PIONEER ENCLOSED ARC LAMPS

We have just received from the Electric Arc Light Co. a very neat catalogue announcing four new numbers of "Pioneer" long-hour lamps, and note that considerable improvements have been made in beauty of outline and detail of finish since their first lamp was put in the market.

Their new standard indoor lamp, illustrated in Fig. 1, has a length of 41 inches and is made of polished brass, with three decorative bands embossed with black background. The lamp is entirely enclosed and takes a 12-inch upper and 4¾-inch lower carbon, the globe being opal. Another indoor lamp of the same general appearance is only 37 inches long,



FIGS. 1 AND 2.—NEW STYLES OF PIONEER ENCLOSED ARC LAMP.

but intended for a 10-inch upper carbon. Fig. 2 represents the new style of "Pioneer" outdoor lamp. This lamp is 41 inches long, and finished dead black, with upper carbon 12 inches in length. As will be seen, the lamp is completely weatherproof, no hood or storm protector being required. It is furnished both with and without ornamental scrolls.

Although but a comparatively short time since entering the field, the "Pioneer" lamp has made a host of friends, as witnessed by the strong testimonials of users printed in the Electric Arc Light Co.'s catalogue.

THE COMMERCIAL CONSTRUCTION CO.

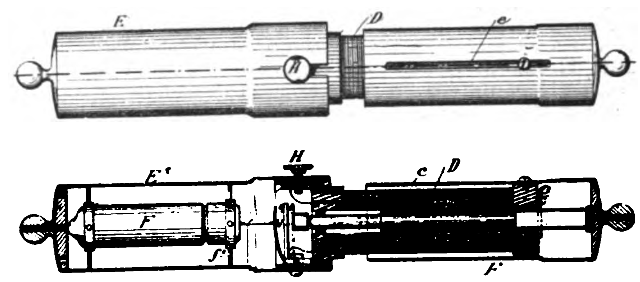
Under the above title a new concern comes forward in New York City for electrical engineering patronage, and with every prospect of doing a large business. It has established headquarters in the Metropolitan Building, Madison Square and East Twenty-third street, and is already engaged with a variety of contract and construction work. The president of the new company is Mr. A. J. Martin, who, though young, has already had a very active career in the field of electric lighting manufacture and installation, and whose latest achievement was his work as the electrical engineer of the Electrical Exposition, at the Grand Central Palace, last May, where a gigantic task had to be put through successfully in a very short time. Associated with him as treasurer of the concern is Mr. Geo. Hilliard and Mr. G. M. Still, a leading oyster merchant, who is secretary. The company will be glad to hear from all parties requiring responsible work done promptly, and will be glad to give estimates with regard to electric railways, electric subways, electric lighting, wiring, telephone plants, etc.

THE LEVY POCKET FARADIC BATTERY.

The accompanying engravings illustrate an improved portable faradic pocket battery.

The exterior casings of the battery form the electrodes and serve as an inclosure for a dry cell, F, and the induction coil, so that the battery can either be held by both ends in the hands or held at one end in one hand, while the remaining part is applied by means of a sponge or other electrode to the part of the body to be treated.

On the reduced portion of the tubular parts surrounding the core are arranged the usual primary and secondary windings of the induction coil, D. The induction-coil is inclosed by a sliding sheet-metal casing, E, which is guided by a longitudinal slot. The end of the metallic sliding casing, E, is made with a hollow knob, so as to form connection with an



electrode, if one is to be used in connection with the battery. For ordinary purposes the sliding casing forms one electrode of the battery. At the interior of the sliding casing, E, is fixed a brass tube, which fits over the core when inserted into the induction-coil and which serves as a damper, which can be drawn in or out.

The secondary winding is connected with a metallic block attached to the interior hollow portion. When, therefore, the switch-screw, H, is turned in sufficiently so as to form contact with the casing, E', the circuit is closed and the induction-coil operated by the battery. By removing the casing, E, sponges, brushes or other electrodes can be applied to the induction coil whenever special application to the body is made, the combination being then held by the casing, E', which forms the other electrode.

This handy combination is the invention of Mr. Leo Levy, of New York.

BALL ENGINES FOR RUSSIA.

The Ball Engine Co., Erie, Pa., the celebrated builders of automatic engines for electric purposes, have recently shipped several engines to Mexico, and one 200 horse-power to Russia. They have an order at the present time for one 400 horse-power vertical cross compound condensing engine, direct connected to Siemens-Halske Electric Co. generator, to be used for electric power in a large steel works at Marlepol, Russia.

TUBING CHICAGO SKY-SCRAPERS.

The Silversmiths' and the Stewart Building are Chicago's two latest additions to its long list of towering office buildings. The Electric Appliance Company are particularly interested in the construction of these two mammoth buildings, as they are to tube them throughout with Armorite.

EDWARD R. KNOWLES.

Mr. Edward R. Knowles, E. E. C. E., long and favorably known in engineering circles as an expert electrical, civil and mechanical engineer, has opened an office in the Tract Society Building, 150 Nassau street, New York, where he will continue his practice as a consulting engineer, making the application of electric power a specialty in addition to his regular engineering work. Mr. Knowles is consulting electrical engineer to the New York and Brooklyn Bridge, having charge of the installation of the new electric traction system which is being introduced in place of the cable traction system now in use. He is also consulting engineer to the "New York Journal," the Mergenthaler Linotype Company, Blake & Williams, and other like corporations. Mr. Knowles has had a long and varied experience in designing, manufacturing and installing electrical machinery. He is prepared to act as expert and engineer in making examinations and

reports, drawing up specifications, laying out and designing electrical installations and supervising the erection of the same.

TELEPHONE LINE MATERIAL.

The demand for telephone line material during the past year has been one of the features of the electrical supply business, and has tended to somewhat relieve the depression caused by the smallness of the demands for electric light material. The Electric Appliance Company has been one of the first companies to recognize this demand, and prepare for it by putting in a liberal stock of telephone line material. It is carrying in Chicago immense stocks of special telephone cross arms, pony insulators, galvanized telephone wire, etc., and is at present prepared to supply almost any demand for these goods.

H. W. JOHNS CO. AT THE CONVENTION.

The H. W. Johns Manufacturing Company will be represented at the St. Louis convention by Mr. J. H. MacLennan, of St. Louis, H. A. Reeves, of the Chicago branch, J. W. Perry, of Philadelphia, J. Emory Meek, of their New York office, and E. B. Hatch and Herbert Luscomb, of the Johns-Pratt Company, Hartford, Conn. The company's exhibit will consist principally of the "H. W. J." car heaters and the well known Moulded Mica line materials and Vulcabeston insulating parts. The Johns Company has revived the sale of the "Hercules" mechanical clip, which is specially adapted for holding the "8"-shaped trolley wire. An exhibition car in the space of the American Car Company will be equipped with the "H. W. J." car heaters.

WHERE TIME IS MONEY.

Calculagraphs are now in constant use for calculating and printing in minutes and fractions of a minute the time which has elapsed in the transmission of toll messages in the following telephone exchanges, viz., American Tel. & Tel. Company (long distance) New York, N. Y.; Buffalo, N. Y.; Troy, N. Y.; Avon, N. Y.; East Onondaga, N. Y.; Boston, Mass.; Springfield, Mass.; West Boylston, Pa.; Philadelphia, Pa.; Temple, Pa.; Hazleton, Pa.; Harrisburg, Pa.; South Williamsport, Pa.; Altoona, Pa.; Maumee, Ohio; Tadmor, Ohio; Cincinnati, Ohio; Cleveland, Ohio; Baltimore, Md.; Terre Haute, Ind.; Evansville, Ind.; Indianapolis, Ind.; Waterloo, Ind.; Providence, R. I.; St. Louis, Mo.; Chicago, Ill.; Milwaukee, Wis.; Washington, D. C.; The Southern Massachusetts Telephone & Telegraph Company, New Bedford, Mass.; Fall River, Mass.; Taunton, Mass.; Brockton, Mass.; Southern New England Telephone Company, New Haven, Conn.; Hartford, Conn.; Bridgeport, Conn.; Waterbury, Conn.; Wisconsin Telephone Company, Milwaukee, Wis.; New England Telephone & Telegraph Company, Boston, Mass.; Worcester, Mass.; Springfield, Mass.; Salem, Mass.; Pittsfield, Mass.; Northampton, Mass.; North Adams, Mass.; Gloucester, Mass.; Greenfield, Mass.; Haverhill, Mass.; Lawrence, Mass.; Lowell, Mass.; Lynn, Mass.; Bellows Falls, Vt.; Concord, N. H.; Manchester, N. H.; Nashua, N. H.; Portland, Me.; Lewiston, Me.; Bangor, Me.; Central Union Telephone Company, Columbus, Ohio; Indianapolis, Ind.; Peoria, Ill.; The Bell Telephone Company of Philadelphia, Philadelphia, Pa.; Pacific Telephone & Telegraph Company, San Francisco, Cal.; Chicago Telephone Company, Chicago, Ill. The Calculagraph is also in use in London, Paris, Berlin, Antwerp and Gothenburg, Sweden.

RAILWAY ARC LAMP.

The need of an arc lamp to operate satisfactorily on the 500 volt circuits of street railway is met by the type brought out by the General Electric Company in 1893 and recently improved. These lamps may be placed in any location where arc lamp light is required, running them in series of ten for the usual street railway voltage. They are automatic in action, simple in construction and require no more attention than the common series arc lamp. Variation of pressure on the trolley or feeder line is taken care of by a rheostat in the circuit.

While such lamps find ready use in the carbarns and around stations, the growing establishment of pleasure resorts, picnic grounds, music pavilions, waterside parks, etc., on the lines of street railways has created a large demand for them. Especially designed for use on trolley circuits, they form the only practical means of illuminating such large areas on the railway line as those mentioned above, and while lending an air of attraction, give a soft light which interferes in no way with the enjoyment of the surroundings, and the sentiments which the summer and fall evenings are supposed to bring in their train.

MICA INSULATOR CO.

Their exhibit at the St. Louis convention will consist in micanite in its various forms, such as commutator segments, rings, tubes, troughs, insulating cloth and paper and peculiar forms of insulation for various types of electrical machinery. Eugene Munsell & Co. will exhibit mica in the sheet, commutator segments and mica as it comes from the mines. Their exhibit will be one of special interest to electricians and superintendents of motor equipment.

A very pretty mica souvenir has been gotten up and will be given to the visiting delegates. A generous supply of blotters will also be distributed, which will remind visitors of the fact when they reach home the place to send their orders for insulation in any form is 218 Water street, New York City, and 153 Lake street, Chicago, Ill. Both the Mica Insulator Co. and Eugene Munsell & Co. exhibit will be in charge of Charles E. Coleman, manager of the Chicago office.

ADVERTISERS' HINTS.

MR. L. S. MARSH, Howell, Mich., invites correspondence with those interested in gas engine plants for private purposes. Mr. Marsh is a consulting and constructing electrician and makes this branch a specialty.

THE CUTTER ELECTRICAL & MANUFACTURING COMPANY have just issued a new catalogue of their "I-T-E" circuit breakers, which will be mailed on application.

THE COLBURN ELECTRIC MANUFACTURING COMPANY, Fitchburg, Mass., illustrate in their "ad" a new type of their well known dynamo. It will be remembered that this company devote particular attention to their machines for electro-plating.

THE HART & HEGEMAN MANUFACTURING COMPANY have brought out a new indicating switch for electric car heaters, breaking circuit at four points. They are single pole and made for 10 amperes at 500 volts.

THE WESTON ELECTRICAL INSTRUMENT COMPANY show a style of their portable galvanometer for bridge work. This is but one of a complete line of portable instruments made for all conditions of service.

THE STANDARD AIR-BRAKE COMPANY refer to the U. S. statutes requiring the equipment of all freight cars with air-brakes before December 31, 1897, and ask: "Which is the more important, the safe transportation of freight or passengers?"

NEW YORK NOTES.

A. K. WARREN & CO., of this city, whose plant was destroyed by fire in the early part of the summer, have in no wise been hindered by the misfortune. After a summer of unusually good business, they are now situated at 451-53 Greenwich street and 15-21 Desbrosses street, where they have larger quarters than before, and improved facilities for carrying on their work. With an undaunted energy they are pushing to secure whatever new and old work offers in their field.

GEO. CALLAHAN & COMPANY, 154 South street, New York, are finding in the electrical field a large market for their specialties. Among these are their belt dressing and their steam joint cement. The belt dressing is very popular and has proved eminently serviceable, besides being reasnoable in price and economical in use. It has been tried and not found wanting, by several electric light companies, and among those in this vicinity may be named the Flemington, Deckertown and Harrison Edison plants in New Jersey. Callahan's steam joint cement is also in extensive use for flange joints, tank joints, piping, screw joint, man holes, hand holes or any other place difficult to keep from leaking. It is a favorite with such concerns as the New Bedford Gas & Electric Light Company, the General Electric Company at Schenectady, the Edison Company in Philadelphia, and the United Gas Improvement Company, as well as hosts of other concerns who cheerfully speak in its praise.

NOTHING is more important in steam work than the joints Leaks at those spots may cause endless annoyance and expense. Just so in electrical work. For want of a good insulating washer or bushing an otherwise excellent piece of apparatus may be rendered useless. Mr. A. O. Schoonmaker, 158 William street, New York, has given special attention to the manufacture of mica washers and bushings of high insulating qualities, and manufactures them in all sizes or thicknesses for any kind of work. He will be glad to forward samples for inspection and trial.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

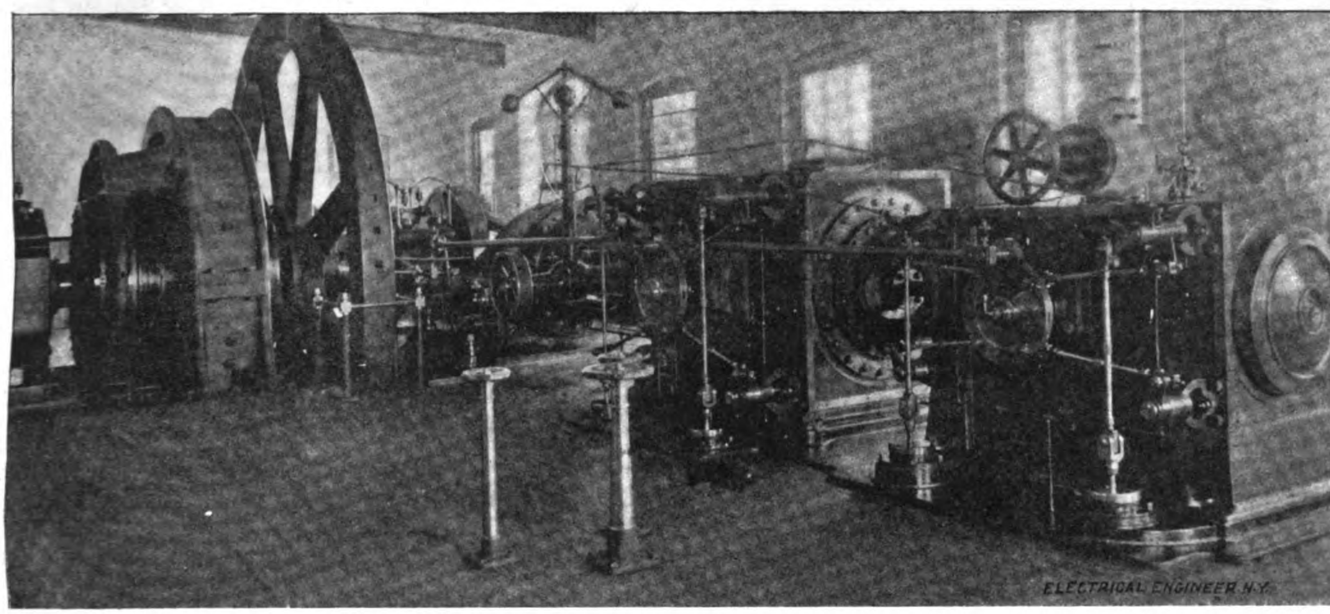
Vol. XXII. OCTOBER 21, 1896. No. 442.

Electric Transportation.

THE FAIRMOUNT PARK TRANSPORTATION CO., OF PHILADELPHIA,—ITS PLANS AND WORK.

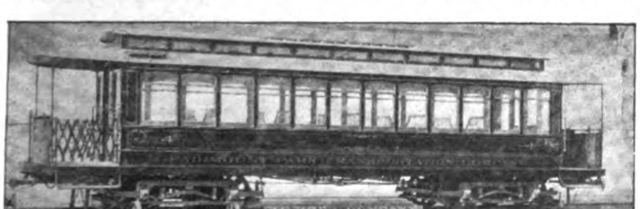
THE first step toward the construction of the road of the Fairmount Park Transportation Co. was taken on July 6, 1889, when the Commissioners of Fairmount Park granted to William Wharton, Jr., a license to lay down, construct, operate and maintain for the term of fifty years from date a passenger road in Fairmount Park. The route, as originally adopted, differs but slightly from the final location. The route in the West Park begins at the intersection of Belmont and Elm avenues, thence with double track skirting the boundary of the park, via George's Hill, to Belmont Summit, near the head of the old inclined plane. From this point a loop extends along the beautiful wooded slopes and hillsides near the Schuylkill River, to Chamounix and the lakes. Thence closely following the northern boundary of the park, it joins the double track at Belmont Summit.

The line is about seven miles long, single track measurement. There is also a branch railway with double track beginning at Ridge avenue, Twenty-third and Dauphin streets, passing Strawberry Mansion, crossing the Schuylkill on a steel bridge, ninety feet high, and connecting with the tracks in the West Park. The railway connects in both the East and West Parks with all the railways running to the park, and is so situated that passengers can be brought to the road by both the Reading and Pennsylvania Railroads. The territory traversed by the road is a part of the park that is practically unexplored by the public, and its opening will mean the enjoyment of a beautiful and heretofore non-frequented region of the park.

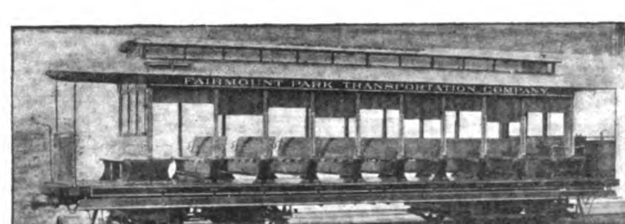


INTERIOR OF POWER HOUSE, FAIRMOUNT PARK ELECTRIC RAILWAY, PHILADELPHIA.

The power house and car house are erected on the line of the Pennsylvania and Reading Railroad, on the westerly bank of the Schuylkill, near the Columbia bridge, and are so situated that coal can be delivered either by railroad or canal at the lowest cost and with the greatest possible advantage. Passenger stations are placed along the road at all desirable points, and stops are confined to these stations. The steam engines, boilers, generators and all other machinery and appliances are of the most approved types found desirable for economy



CLOSED CAR, FAIRMOUNT PARK ELECTRIC RAILWAY.

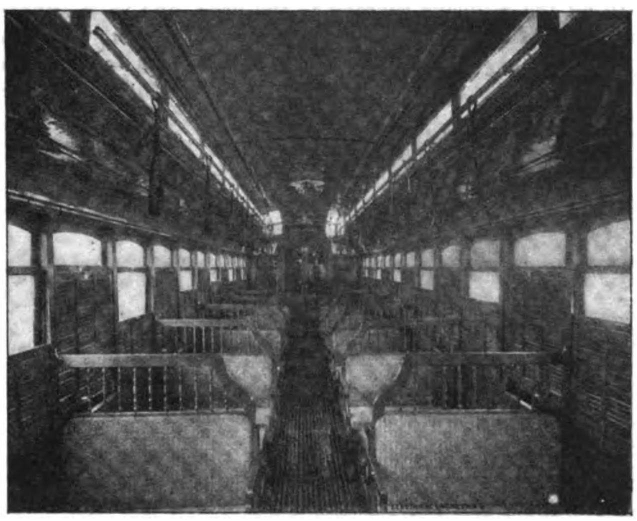


OPEN CAR FAIRMOUNT PARK ELECTRIC RAILWAY.

Bridge Across the Schuylkill for the Fairmount Park Trolley Road.

and service. The fare for the round trip is 5 cents, and in company with adults children under five years of age are allowed to ride free. This feature will add largely to the popularity and business of the company.

Although the main part of the business will consist in carrying people for pleasure, yet there must of necessity be a large amount of travel over the line, as it will provide a short cut from the northern and northwestern parts of Philadelphia



Interior of Fairmount Park Railway Car.

to West Philadelphia. This will include Germantown, Roxborough, Manayunk, Falls of Schuylkill and all the adjacent localities which the extended area of the park has up to this time cut off from all direct railway communication with other sections of the city.

No grade crossings exist at any roadways, bridle paths, or foot paths, and the tracks over the Schuylkill bridge are entirely separated from carriage and foot travel. All ravines and roadways are crossed, when overhead, by steel viaducts, and when below grade by stone masonry tunnels.

The cars used are eight-wheeled Brill cars, having a seating capacity for seventy-two persons. They are made up into trains consisting of one motor car and one trail car. The motor cars are equipped each with four "G. E. 1,000" motors, electric brakes, and two K. 4 controllers, which regulate the current actuating both motors and brakes. The trail cars are equipped with electric brakes on all four axles. Both motor and trail cars are equipped with especially powerful hand brakes in addition to those already mentioned. At present the road is supplied with sixty cars, thirty motor and thirty trailers.

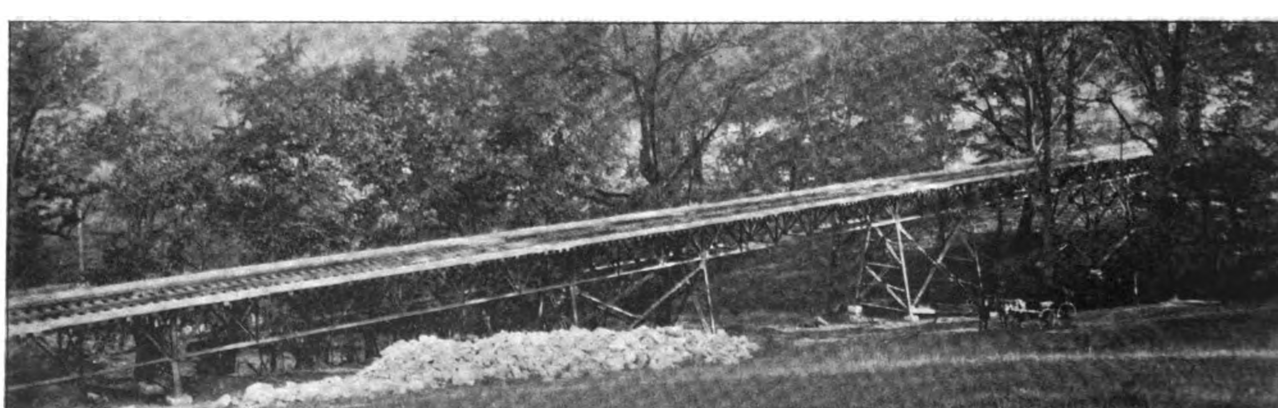
The roadway is graded so that there is no ascending grade greater than four per cent. slopes, banks and space between tracks being filled to the top of the rail, and sodded or planted with grass seed. To make the permanent way as little unsightly as possible, the slopes are made of warped surfaces,

Arch for Carriage Drive, Fairmount Park Electric Railway.

so as to avoid a rectilinear perspective. The cuts are very open and planted with shrubbery.

The track and overhead construction are of especially heavy character. The rails are 90-pound T rails, 36-inch angle bars, with cast iron chairs at the curves. The bonding is the Harold P. Brown plastic bond. These are put in double. The rails are connected to the negative bars with ten 1,000,000 circular mils copper cables, whereby a smaller drop of potential in the ground circuit is obtained than in any other road constructed up to the present time.

The feeder system is made up of a number of braided lead encased paper covered cables of 500,000 and 650,0000 c. m. The maximum drop of potential in the entire system is 10 per cent. The average drop will be under 5 per cent. The cables are drawn into a subway of the ordinary type, built of

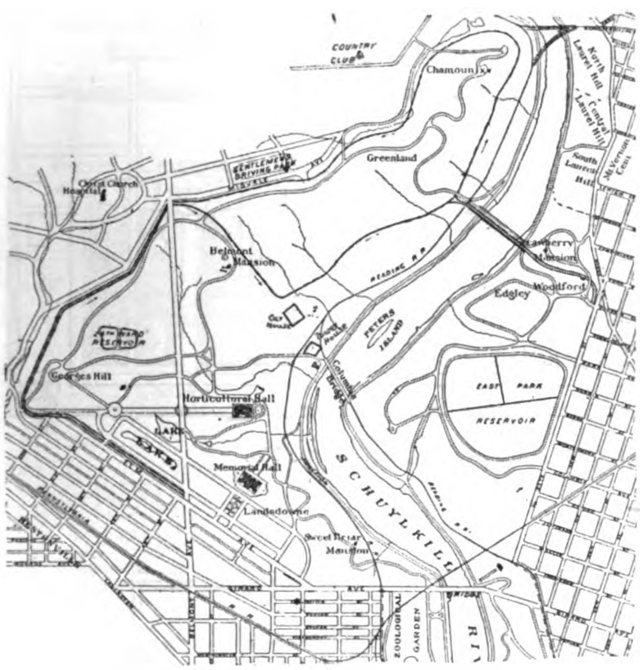


A Viaduct of the Fairmount Park Electric Railway, Philadelphia.

treated wood ducts, the distance between manholes averaging 500 feet. The trolley wire is of No. 0000 hard drawn copper, with especially heavy poles, span wire and fittings. In fact, owing to the unusually severe service to which this road will be subjected, more like that of a steam railroad, the entire construction and equipment is of an extra substantial character. This has, therefore, made special construction necessary.

The agreement with the Park Commission having prevented any grade crossings, the total number of bridges, including that on the Schuylkill River, is twenty. These are all of the highest grade of work, both from the standpoint of the engineer and of the artist, as shown in some of the accompanying illustrations. The bridge over the Schuylkill River is to have a forty-foot roadway for carriages. On the north side of this roadway is a twelve-foot sidewalk, while on the south side are the two railroad tracks. The bridge will be paved with asphalt, and will be lighted by twelve arc lamps on ornamental posts. The current for these will be supplied by the railway company.

The rolling stock consists of thirty motor and thirty trail cars, as mentioned above. These are each mounted on two



PLAN OF FAIRMOUNT PARK ELECTRIC RAILWAY.

four-wheel trucks. The wheels are thirty-three inches in diameter, and four inches tread, with extra heavy flanges.

The car shed is 425 feet long by 114 feet wide, constructed in two bays. Aside from its substantial character and handsome exterior, as required by the Park Commission, it differs but little from the regular car shed of the larger roads. Every effort has been made to have the powerhouse an ornament to the park. It is built of two shades of Pompeian brick, with granite belt courses and a base course, eight feet high, also of granite. The cornice and ornaments, pipes and roof balustrade are of copper. The roof is of slate. There are skylights in the roof of the engine room.

The engine room is 156x55, and the boiler room 156x36. Extending under the tracks of the Pennsylvania and Reading Railroads is a coal vault entering into the boiler room of sufficient capacity for storing one month's supply of coal.

The station is equipped with three tandem compound Corliss engines directly connected to 500 K. W. General Electric generators. They move at a speed of 90 revolutions per minute. These engines were built by Robert Wetherill & Co., of Chester, Pa., who also furnished the boilers. These are of the Berry vertical type, have water grates and fire tubes. There are six boilers each of 250 horse-power. The condensers and pumps are furnished by the Blake Co. The air pumps are of the twin vertical type, admiralty pattern.

Instead of a stack or chimney, induced draught and an economizer is used. Experience in Philadelphia has shown that this arrangement not only effects a great saving in coal, but is of further benefit in that it diminishes the scale in the boiler. In cases where the economizer has appeared not to pay for the cost of installing, its failure, on investigation, has been found to be due to mismanagement. The engine room is equipped with a 20-ton traveling crane, made by William Sellers & Co.

The officers of the Fairmount Park Transportation Co. are as follows: President, George S. Gandy; secretary and treasurer, Ellsworth H. Hults; engineers, Edward B. Ives and Axel H. Engstrom; engineers in charge of construction, T. A. Merryweather, permanent way; W. N. Walmsley, electrical; A. Kuylenstjerma, mechanical.

ST. LOUIS ELECTRIC RAILWAY POWER STATIONS.

ST. LOUIS was among the first of our large cities to adopt electric traction and, with possibly a single exception, has the largest mileage of electric railway of any city in the country. Having begun comparatively early to avail itself of the facilities offered by the electric method, the stations of the various companies present excellent examples of the rise and growth of the art and the gradual replacement of old by improved apparatus, as experience has been gained in operation. The members of the American Street Railway Association, now convened at St. Louis, will therefore have an excellent opportunity of making comparisons and drawing conclusions from the work of their St. Louis brethren, some of whom have paid dearly for their experiences. We cannot, within the limits of the space at our command, enter into a detailed description of each station, but we have selected from among them a number which will give a good idea of their general character.

UNION DEPOT RAILROAD POWER STATION, NO. 1.

Perhaps as good an example of the changes and progress made in electric railway power house equipment as could well be found is that presented by the Union Depot Railroad Power House, No. 1. This station was designed at the time when the best practice was considered to be the operation of a large number of small units belt driven from countershafts, and when direct connected units had hardly entered the domain of discussion, let alone of practice, in railroad work. With the lapse of time the apparatus was changed until at present the station contains just enough of the older type of apparatus to make all the more striking the great strides during the past six or seven years.

The station is situated on the block bounded by Geyer, Missouri, Allen and Jefferson avenues. The original station was started early in 1890, then occupying a space 85 x 129 feet for the engine room and 54 x 109 feet for the boiler room.

The initial engine plant consisted of two Hamilton-Corliss engines, one 24 x 48 inches, and the other 20 x 48 inches. These engines were belted to a jackshaft, which in turn drove a 6-inch countershaft by means of a one-inch rope drive. The dynamo equipment consisted of 14 Thomson-Houston D 62 dynamos, which were likewise driven from the countershaft by means of a ¾-inch rope drive. Experience, however, soon proved the rope drive to be unreliable and belts were substituted in their stead. Increase of traffic during the first year's operation necessitated an addition to the power plant and an extension of the building was erected and another engine added, together with eight additional dynamos, making twenty-two in all.

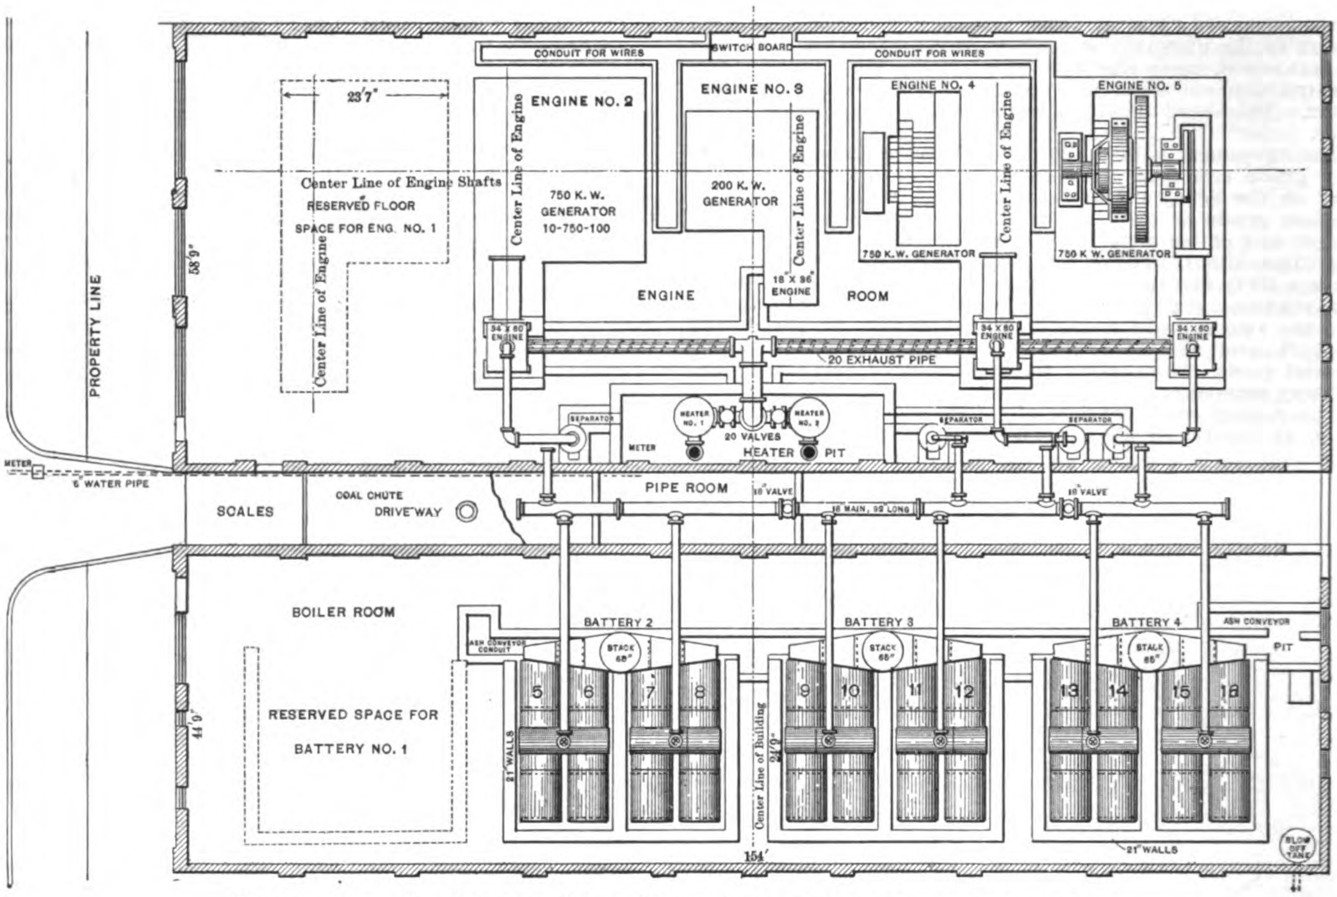
It was not long, however, before further demands were made upon the station, which was enlarged to the dimensions shown in the engraving, p. 388. The equipment early in 1895, consisted of two Porter-Allen engines, 20 x 36 inches, direct coupled to two General Electric M.P. 400 generators and seven D62 Thomson-Houston generators, driven by a 28 x 34-inch Hamilton-Corliss engine, together with eight 250 horse-power Heine boilers. The original equipment of the D62 dynamos with their engines being thrown out of service, was removed from the station. In the fall of last year a General Electric 1,500 kilowatt generator, direct coupled to two Allis engines, was installed with an addition of two 500 horse-power Heine boilers. This unit is the largest in the city.

The destructive cyclone which visited St. Louis in May last, nearly destroyed the entire plant, the two brick smokestacks falling upon the engine house. Most of the machinery was repaired, however, but the engines constituting the original plant have not been put in service since the disaster.

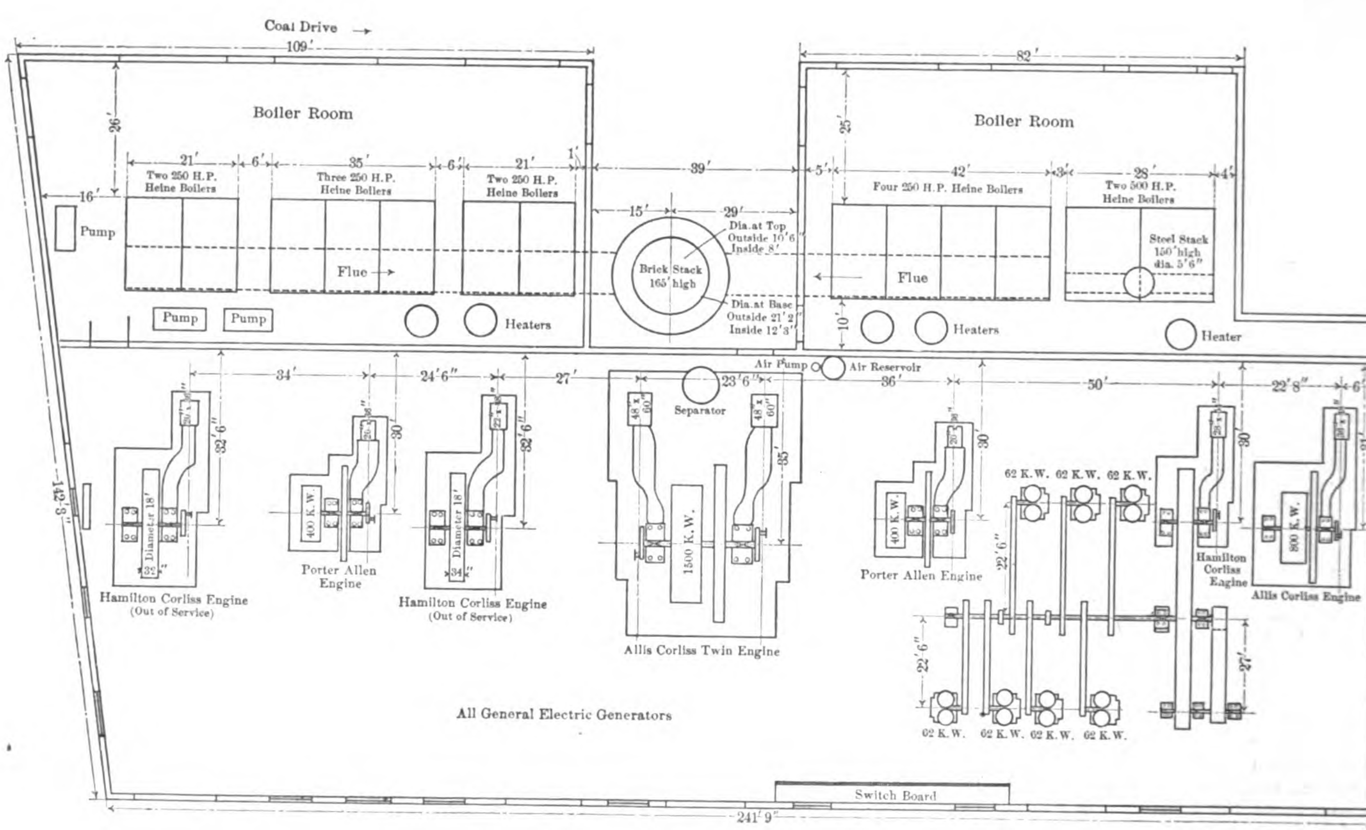
The Union Depot Railroad also operates another power house in North St. Louis.

THE ST. LOUIS AND SUBURBAN RAILWAY POWER STATION.

As was the case with a number of companies in St. Louis, the St. Louis and Suburban Company, operated originally the cable system, but the owners were soon converted to the benefits of electricity. The cable power house proving too



Plan of Power Station, Cass Ave. & Fair Grounds Railway Co., St. Louis, Mo.



GEYER AVENUE

Plan of Power Station No. 1, Union Depot Railroad, St. Louis.

small for the electric requirements, the new power house was located at De Hodiamont, close beside the Wabash Railroad track, and went into operation in the fall of 1891. The original electric equipment consisted of eight 75 kilowatt and two 80 kilowatt generators driven from countershaft by Hamilton-Corliss engines. Three batteries of two boilers each were installed at the same time, the entire equipment being placed on the side facing Vendome avenue, in the engraving below. A month after the plant had gone into operation, the old cable plant was abandoned and its engines removed to the new electric power plant, forming a twin arrangement with the one already installed.

Two years later, in 1893, the engine room was extended and two additional Thomson-Houston 80 kilowatt generators installed driven by a Hamilton-Corliss engine, which was taken from the older portion of the house. Another change was made by taking one of the twin engines and moving it to the east end of the station, where it is belted to two Thomson-Houston, 300 horse-power dynamos. Additional power was also gained by extending the line shafting and belting to it two 270 horse-power generators. The rearrangement is shown in the diagram of the plant.

During the past year the St. Louis and Meremec River Railroad was built, which road had entered into a contract with the Suburban Company, to furnish it with power. This necessitated still further additions to the generating plant. They were begun early this year, and consisted of a 60-foot extension to the engine room and 118 feet to the boiler room. Two Hamilton-Corliss engines direct connected to two General Electric 800 kilowatt generators were put in and eight new boilers added.

The boilers in this station have all been provided with the Hawley down draft furnace and each battery has a steel stack 150 feet high. The boilers are fed with city water. This can be led directly to the pumps, to the heaters, or to the boilers, or to hot wells in the boiler room. The water of condensation from the exhaust pipes, traps, etc., is discharged into the south well. All scum and dirt rising to the top is run off into the sewer, leaving the north well clean so that its water can be pumped into the boilers. The general practice, however, is to run the water through the heaters and pumps and then to the boilers. Four closed heaters are installed at this station, two Goubert, one O'Brien, and one Baragwanath.

THE CASS AVENUE AND FAIR GROUNDS RAILWAY COMPANY'S POWER STATION.

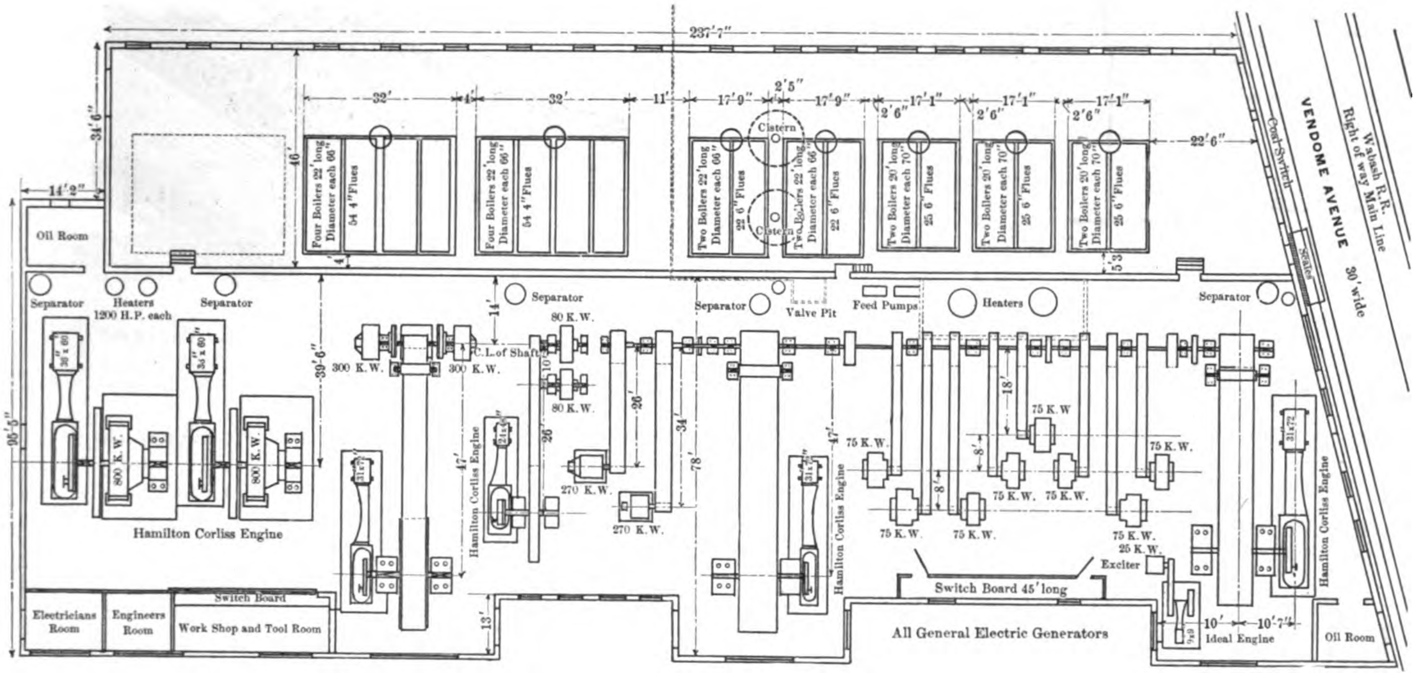
The Cass avenue and Fair Grounds Railway is one of three systems controlled by the National Railway Company, the other two stations operating cable roads.

The Cass avenue Station plant is modern in every respect, consisting of four Corliss engines, three of which are direct connected to 750 kilowatt General Electric generators, and one unit of 200 kilowatt capacity. Indeed it is worthy of special note that the apparatus in this plant was the first of the direct-connected type for railway work installed by the General Electric Company.

The plant was originally intended to operate 70 motor cars. Since then over 100 motor cars have been added, as well as numerous trailers. This has been done without increasing the power equipment at the station.

The boiler room contains twelve tubular boilers 22 feet by 66 inches, with a total capacity of 3,000 horse-power. The Hawley down draft furnace is employed. The grates consist of two-inch water pipes which connect with two water drums at either end of the fire box. The draft being down, the fire is brought in contact with the water pipes forming the grates, thus adding materially to the steaming capacity and efficiency of the boilers.

The arrangement of the boiler house permits of the ready handling of coal. The floor of the boiler room is 12 feet below that of the engine room and is separated from it by a driveway. The coal carts enter this driveway and dump the coal through manholes into chutes which lead directly to the front of the boilers. An excellent system of station accounts is kept and records are made of the performance of engines and dynamos. These records are regularly worked up and the results entered in books kept specially for that purpose, and reduced to coal and water consumed per motor car miles run. In calculating the total number of motor car miles, a trail car mile is taken as equivalent to one-half a motor car mile.



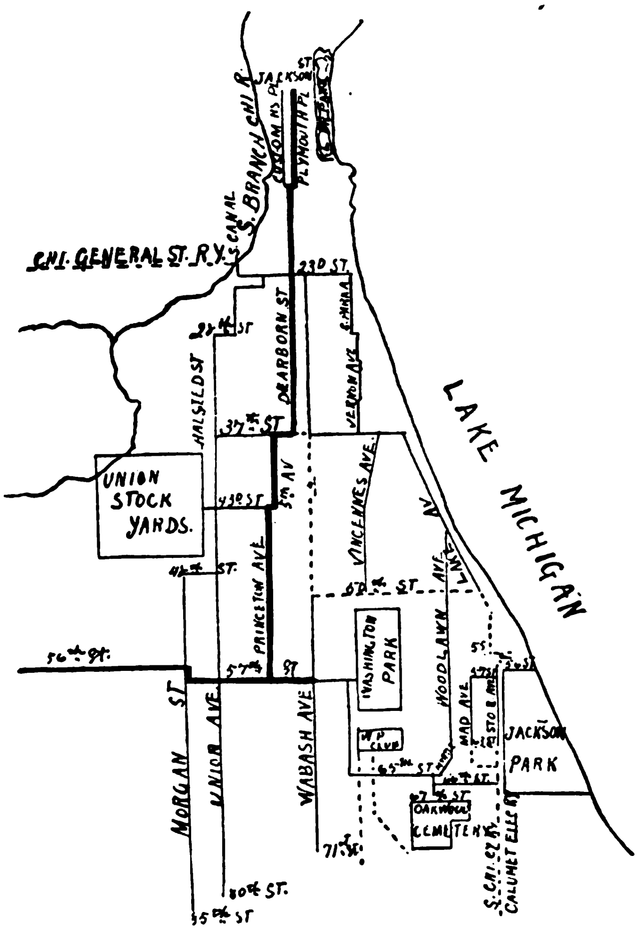
PLAN OF POWER STATION, ST. LOUIS & SUBURBAN RAILWAY, ST. LOUIS.

A LARGE CONDUIT RAILWAY SYSTEM FOR CHICAGO.

FOR some time past public attention in Chicago has been arrested on the plans of the local General Electric Railway Company, in which the Love Traction Company, owning the Love conduit railway system, is largely interested. It will be remembered that the Love open conduit was tried in Chicago once before, in a crude way, but that owing to faulty construction it was abandoned. After a lapse of four years, work is resumed, the General Company having secured franchises over a territory represented in the accompanying map, where the heavy lines indicate the proposed conduit system. The first line to be constructed by the company will have a downtown outlet at Jackson street. As indicated by the heavy lines in the diagram, it will follow Plymouth place to Fourteenth street, thence in Fourteenth to Dearborn, in Dearborn to Thirty-seventh, in Thirty-seventh to Fifth avenue, in Fifth avenue to Forty-third street, in Forty-third to Princeton avenue, in Princeton avenue to Fifty-seventh street, west in Fifty-seventh to Morgan, in Morgan to Fifty-sixth, and thence to Western avenue. A branch will also connect with Wabash avenue on Fifty-seventh street.

It is stated that bonds to the extent of $5,000,000 have been

underwritten by a New York banking house, and J. P. Morgan & Company have been named; but the statement is without confirmation up to date. Mr. Albert G. Wheeler, of the Love



Lines of the General Electric Railway, Chicago.

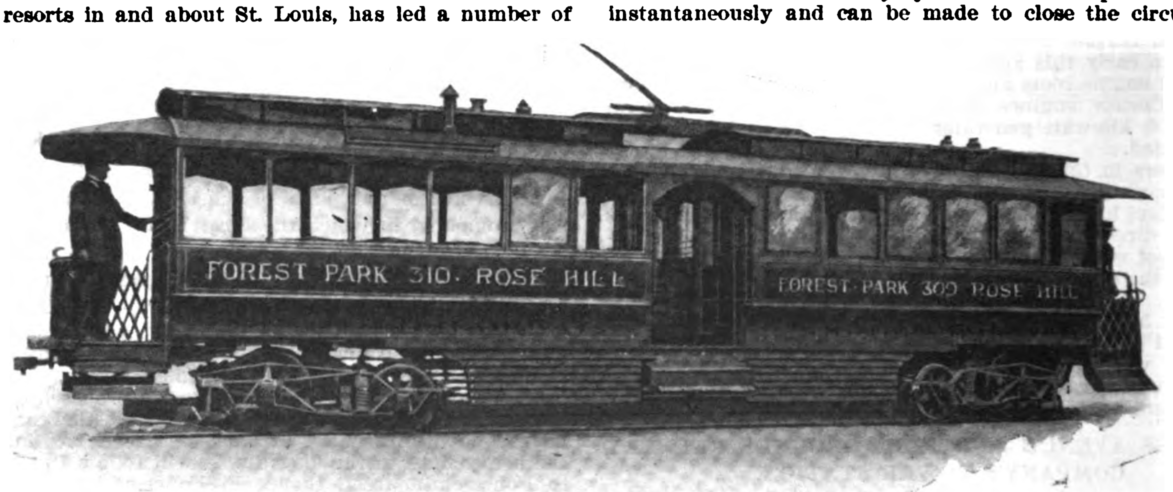
system, is one of the men most prominently connected with the enterprise.

DOUBLE TRUCK VESTIBULE CAR IN ST. LOUIS.

In keeping with the diversity of apparatus in the power stations of the electric railway companies of St. Louis is the variety of their rolling stock. The heavy night and morning traffic as well as that engendered by the numerous pleasure resorts in and about St. Louis, has led a number of the companies to the adoption of large cars. One of these is shown in the accompanying engraving.

This car is of the double truck vestibuled type, built up by splicing two 16-foot cars together. It has an entrance at the middle, thus expediting the time required for boarding and letting-off in busy hours.

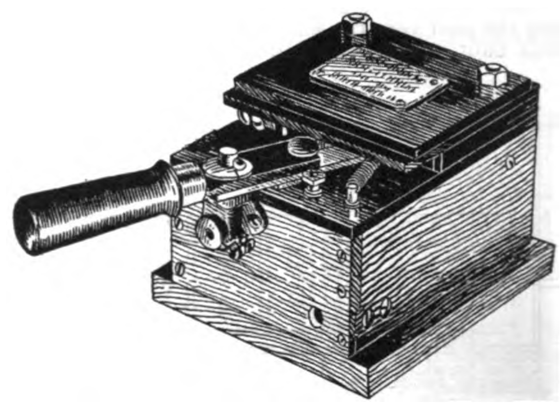
The seats in each compartment are placed longitudinally at the sides, and a short seat is also placed in the vestibule opposite the entrance. The car has a seating capacity for 53 persons, while when crowded 140 can be carried, the total standing room being 95 square feet.



Double Truck Vestibuled Car, St. Louis.

G. E. AUTOMATIC CIRCUIT BREAKERS FOR ELECTRIC CARS.

The motors and other appliances of street car equipments have hitherto depended for protection against injury from excessive currents on the common safety fuse in its box placed beneath the car platform and more or less inaccessible. The blowing of the fuse entails delay until the motorman replaces it, and as a certain time is taken by a safety fuse to blow, considerable injury may be done to the motors and



G. E. Automatic Railway Car Circuit Breaker.

other car apparatus in the interval in which it is reaching the melting point.

To avoid this delay the General Electric Company conceived the idea of making the main motor switch an automatic circuit breaker instantaneously operating and easily reset. This device has been perfected and the automatic circuit breaker for street railway car equipments, known as the "M" circuit breaker, is now being manufactured. In appearance it resembles the main motor switch and in every way answers the purpose of one. It is intended to be placed in the same position under the car hood. The handle is so arranged that the breaker may be opened and closed by hand in the same way as the standard main motor switch. The device is provided with magnetic blow-out and can thus break the severest short circuits without injury to itself. It opens the circuit instantaneously and can be made to close the circuit immediately after it has been opened, thereby avoiding delay to the car.

The "M" circuit breaker is so constructed that an automatic

counter may, when desired, be introduced into it, in such manner as to preclude any tampering with it by the motorman. This registers every time the circuit breaker opens automatically, and affords an excellent method of detecting the improper handling of the cars. It gives to the inspector a means of discovering those motormen who have turned on the current too suddenly, calling for an excessive amount of current.

The "M" circuit breaker is adjustable. By a simple movement of the calibrating spring the breaker may be adjusted to open at any predetermined amount of current within a certain range. The device is manufactured for 75—150 amperes and 150—250 amperes, the first figure representing the lowest tripping point, the second the maximum carrying capacity for steady loads. The adjustment may, however, be made to break the circuit at currents considerably higher than the maximum carrying capacity. This device will be exhibited at the St. Louis convention.

CONTACT SHOE AND BRAKE ON THE NEW YORK, NEW HAVEN AND HARTFORD RAILROAD.

At the time The Electrical Engineer published a description of the electrically operated railroad between Pemberton and East Weymouth on the Old Colony Division of the New York, New Haven and Hartford system, particulars regarding the method of braking and contact were not obtainable. We are now enabled to give these.

It will be remembered that on the line from Pemberton at the extreme end of Nantasket Beach to Nantasket Junction, a distance of 6.91 miles, the cars are operated by overhead trolley contact. From Nantasket Junction to East Weymouth

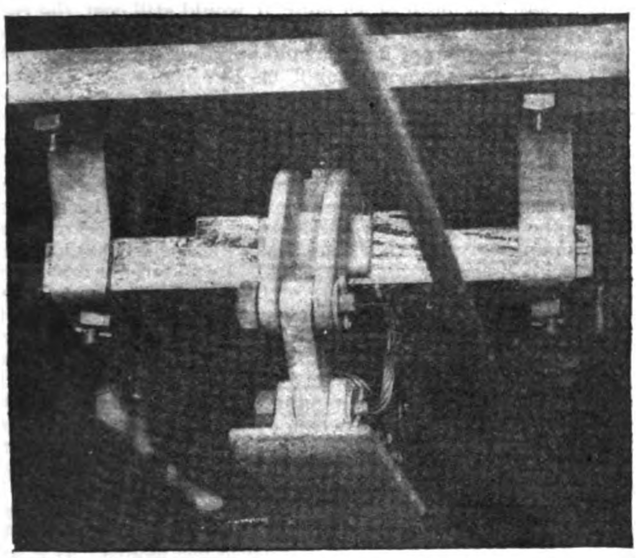


FIG. 1.—CONTACT SHOE, N. Y., N. H. & H. R. R.

the electricity is taken by means of the sliding contact shoes from a third rail laid in the center of each track. When the cars start from the Junction station, momentum is given to the car by electricity taken from the overhead wire and it is carried over to the third rail. The trolley then slips from the termination of the overhead wire, is pulled down and hooked and the shoes, one of which is illustrated in Fig. 1, come into contact with the surface rail. A knife switch under the hood of the car being closed, the current from the rail is thrown into the motors and the operation of the train is continued without interruption.

One shoe is placed between the axles of each truck, immediately under the king pin. It is suspended by two links, and thus hangs loosely. This allows it to slide over the surface of the third rail without difficulty and to make perfect and continuous contact. The distance between each of the shoes on a car is 33 feet; thus at crossings, where no third rail is laid, less than 30 feet wide, one shoe is always in contact with the end of one section or the beginning of the next; at wider crossings the impetus of the moving car brings the shoes into contact again before the car can come to rest. Each shoe is a cast iron plate twelve inches long and five inches wide. It weighs about 20 pounds and is connected to the motor by a flexible cable.

The air for the brakes is supplied by an electrically driven air compressor, Fig. 2, automatically controlled by the air pressure itself. The apparatus consists of a double vertical air pump with single acting cylinders, 5¾-in. x 7-in. stroke, directly connected to a series motor, the lower field of which

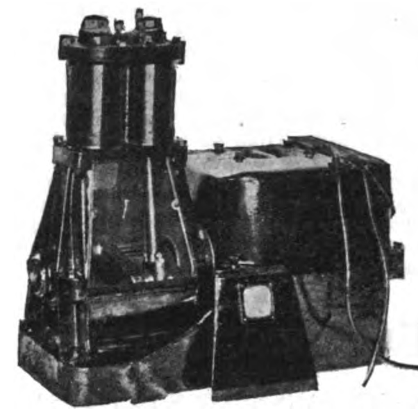

FIG. 2.—AIR COMPRESSOR ON ELECTRIC CAR OF N. Y., N. H. & H. R. R.

is extended to form the base of the air pump. The connection between the two is thus rendered very rigid. The capacity of the pump is 52½ cubic feet of free air per minute working against 90 pounds pressure per square inch. At this pressure the speed is 250 revolutions at 600 volts.

The air compressor is piped directly to the main reservoir, and is controlled automatically by a pneumatic governor consisting of a cylinder containing a piston working against a

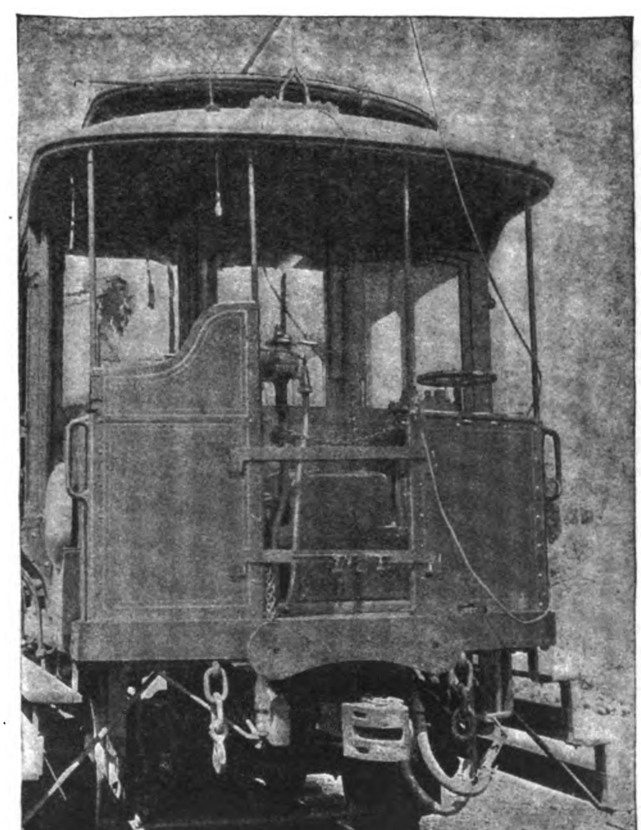

FIG. 3.—PLATFORM, ELECTRIC CAR, N. Y., N. H. & H. R. R.

spring. The action of this automatic control is as follows: The pipe running from the main reservoir enters the cylinder below the piston. As the pressure rises the piston is forced upward against the spring. The other end of the piston rod carries the contacts through which the pump motor circuit is made and broken. Any arcs that may be made when the

contact is broken are blown out in a magnetic field the coils of which are connected directly in series with the motor.

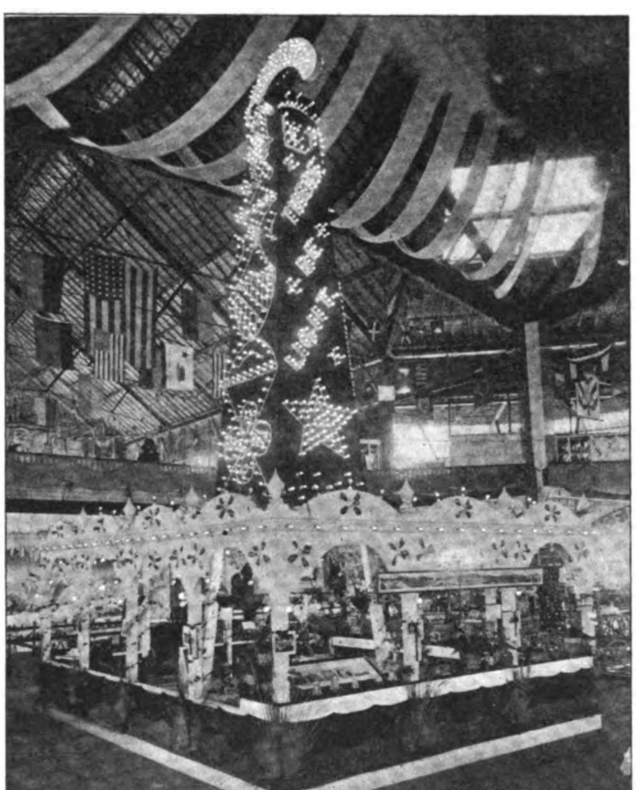
As the pressure in the reservoir falls from five to seven pounds, the piston is forced back into its normal position by the spring. The contacts are pushed down to their seat, the circuit is closed, current flows to the motor and the compressor starts. The circuit remains closed until the pressure reaches normal when it overcomes the force of the spring, forces the piston upward, separates the contact, breaks the circuit and the motor stops. This operation is repeated automatically, the combination of motor and pump requiring practically no attention. These automatic governors can be adjusted to any pressure from 45 to 100 pounds and work on a difference of from five to seven pounds in pressure.

The development of the combined air pump, motor and automatic governor is due to the General Electric Company. It is of recent design and takes the place of the oscillating cylinder type of air pump with which the motor cars were originally equipped.

ELECTRIC LIGHTING.

LONG DISTANCE TRANSMISSION TO THE SACRAMENTO STATE FAIR.

LAST month, at the successful State Fair at Sacramento, Cal., another interesting demonstration was given of long distance current transmission. The Sacramento Electric, Gas and Railway Co. made a fine exhibit in the shape of the beautiful tower, a cut of which is here presented. The height of this tower was 40 feet to the top of the sign, and the floor base was 20 by 25 feet. The number of lamps was 1,600, in six rows, which were flashed in seven combinations. The current was delivered to the tower from the Folsom three-phase circuits, the generating plant being twenty-two miles



TOWER AT SACRAMENTO FAIR, LIGHTED BY CURRENT FROM FOLSOM, 22 MILES AWAY.

away. The tower body was of black, studded with the lamps. On one side was the sentence "Let there be light," and on the opposite side were the names "Edison," "Thomson," "Franklin," and "Tesla." On the two remaining sides were arranged shields, scrolls, stars and other pleasing designs in colored lamps. Around the tower was a booth, the roof, pillars and counters of which were white. This also was tastefully decorated with lamps. The practical part of the exhibit in addition to this evidence of long distance work, consisted of an oven, boiler, tea kettle, chafing dish, curling iron, farina boiler, hot water urn, glue pot heater, laundry iron, tailor's iron, and four fans, all of which were operated by current from distant Folsom. The exhibit was in charge of Mr. J. H. Lawrence, under whose direction it was also set up.

CHARGING FOR ELECTRIC CURRENT ON THE WRIGHT DEMAND SYSTEM.—HOW TO ADJUST RATES SO THAT EVERY CLASS OF CUSTOMER SHALL BE PROFITABLE TO THE COMPANY.

BY R. S. HALE, E. E.

THE expenses of an electric company are of two kinds, of which the first consists of the outlay up to the moment of supplying the current, and the second of the actual expense while supplying the current. The expense of getting ready to supply current or the fixed expense consists of interest, dividends, part of the labor, all the management and legal expenses, etc., while the coal bill forms almost the only item of expense for actually running the machinery. Now if the price per kilowatt hour be 15 cents, and the customer burns his lamps one hour, the company gets 15 cents, of which 13 cents goes for management, dividends, etc., while the balance goes for coal, etc. If the customer burns his lamps a second hour it costs the company nothing more for management or interest or any of the fixed expenses, and if the company continued to charge 15 cents per kilowatt hour it would make a profit of 13 cents on a cost of 2 cents, or, roughly, 650 per cent. On the other hand, if the customer should burn his lights no more than one-tenth of an hour, it would still cost the company 13 cents for interest, etc., and though the coal, etc., for 1-10 hour, at 2 cents per hour, would only be 2-10 of a cent, the total cost to the company would be 13.2 cents per kilowatt, against 1½ cents per kilowatt income, or a loss of 88 per cent.

The following example will show the method by which any company may easily determine the amount of its fixed and running expenses, for it must be remembered that even part of the coal bill, namely, the cost of coal for keeping up pressure in the pipes and for banking fires, this coal being used whether the engines run for one hour or ten, is a fixed expense.

Let us suppose we have a company which sold 9,000 kilowatt hours in an average summer month, July, for example, and that the expenses, including 1-12 of the year's dividends, interest, etc., were $2,300. In December the expenses run up to $2,510, while the company sold about 16,000 kilowatt hours, or 7,000 kilowatt hours more than in June. The fixed expenses for management, dividends, etc., were, of course, no more in December than in June, so that the $210 extra expense in December was all running expense. As this extra expense of $210 was incurred in order to sell 7,000 more kilowatt hours, the extra cost was only $210÷7,000 kilowatt hours, or 3 cents per kilowatt hour. If no current at all had been supplied in June the company would then have saved only 9,000×3 cents=$270, and its expenses would have been $2,300 minus $270=$2,030, which would be the fixed expense per month. If it had supplied no current in December it would have saved 16,000×3=$480, and its fixed expenses would have been $2,510 minus $480=$2,030, or just the same as in June. A plant of this size would be prepared, after allowing sufficient reserve, to supply a maximum demand of about 500 kilowatt. The fixed expenses are then $2,030÷500=$4.06 per kilowatt of plant per month, or $48.72 per kilowatt of plant per year. The result is that if a customer uses 1-500th of the company's plant, in other words, if he burns lights equal to one kilowatt at one time he costs the company $48.72, even if he burns them only one hour in the year, while after that one hour in the year it costs the company only 3 cents per hour more for each hour he burns them.

The table given below shows the resulting cost per kilowatt hour for different fixed expenses and running expenses.

Now, in general, a company does not want to lose so much on one-half its customers that it must charge an exorbitant rate to the other half in order to come out even. Yet it is apparent from the above table that if a company charges 20 cents per kilowatt hour to all customers it loses from 80 cents to $1.80 on every thirty-hour per year customer, and makes from 11 to 18 cents on every ten-hour-a-day customer. Of course, in particular cases the company may charge more or less than enough for a fair profit, as, for instance, when it wants to secure a particularly influential customer, or to have a use for plant that would otherwise be idle, but these are obviously only temporary expedients, and it is apparent that

some system of charging is needed which will draw a profit from the short hour customers without making them feel that they are unfairly treated, and will give a low price to those customers who use their proportion of the plant long hours.

The Wright Demand System.—The Wright "demand system" is based on this principle. It does not interfere with giving an extra discount to the customer who has a very large bill, since one big customer needs less clerical force and is in general less bother than ten small customers. But the Wright system assumes that each customer should pay the fixed expenses, including dividends, etc., on the proportion of the plant that he uses, and in addition should pay running expenses only for the hours he actually uses the plant.

In order to accomplish this the watt hour or ampere hour meter is not sufficient, since the amount of plant required does not depend on the total number of kilowatt hours, but on the maximum current which is used at any one time. In order to show this and to show who are the long and short hour customers it is necessary to have in addition a demand meter to read the maximum current used by the customer at any one time during the year, for this is what determines the plant that must be installed at the central station in order to supply him.

COSTS PER K. W. HOUR.

Yearly fixed expense $60 per k. w. of plant or of demand.

Additional price per k. w. hour as per head of table.

10	3,000	4	6	8	2
24	7,200	3 5/12	5 5/12	7 5/12	1 5/12

Methods of Charging.—The kilowatt hours used by the customer being known from the watt hour meter, and the maximum current used at once from the demand meter, the matter of arranging the charges may be done in several ways. The three following will be found to cover nearly every case.

The first method is to make a list price per kilowatt, and then give, say 10 per cent. discount, to the customer who averages two hours' use of his demand, 15 per cent. discount for three hours' use, and so on.

The second method is to charge 15 cents per kilowatt for the first two hours, and say 5 cents per kilowatt after this. We determine by the demand meter that a customer uses investment corresponding to 3 kilowatt, that being his maximum for the year, then 2 hours × 25 business days is 50 hours per month. His demand meter showed 3 kilowatt during the heavy load, hence he would be charged 15 cents per kilowatt hour up to 3×50=150 kilowatt hours in each month, and 5 cents per kilowatt hour for all kilowatt hours for over 150. This, as well as the discount system, has the disadvantage that the very short hour customer still uses as much plant as the moderate or long hour customer, and unless he should guarantee payment for one or two hours' use of his demand pays you practically nothing for its use.

The third method, which seems best adapted to American practice is to charge a fixed amount per year, payable in twelve equal installments, if desired, as rent for the investment. This is from $30 to $60 per kilowatt per year. Thus, if a customer's demand meter shows that some time during the previous year he used 4 kilowatt (80 lights), his charge for rent would be $240 per year, at $60 per kilowatt, or $20 a month. In addition, a charge of 3 or 4 cents per kilowatt hour would cover the running expenses. Under this scheme, although each customer's bill would be enough to cover his share of the fixed expenses as well as his share of the running expenses, no customer would show profit enough to warrant the company's giving him a lower price except under very unusual circumstances.

These methods may be modified in whole or in detail to suit the circumstances of each company, and the particular prices would be different for each company. Thus the running expenses per kilowatt will be far larger if coal is $5 a ton than if it is $1.50. See table of costs.

Special Advantages of the Wright System.—Every electric company has in its district many gas and oil users, who burn their lights long hours and cannot, therefore, afford to put in electricity at the present tariff. The Wright system gives a chance to offer to such a lower price at a good profit to the company. In addition it offers a lower price at a greater profit to the company to all customers who will use their lights longer hours, and that there are many such is well known to any one who will notice how many houses there are where oil or gas is still used in dark corners where a constant light is required. Under a tariff which makes a very low charge for long hours the advantages of appearance and health will make electricity preferable.

The Wright system will discourage no customers except those who do not pay their proportion of the fixed charges, and who are, in fact, a loss to the company. If desirable these customers may be retained under the old system, though it is usually better that they should be allowed to drop off, thus making room for really profitable customers.

The Wright Demand Meter.—The meter to be used needs special consideration. It must show the maximum current used, it must be accurate, it must be such that it cannot be tampered with by the customer, it must be slow acting, it must not show a short circuit that acts only for a second (there is no part of the investment that will not stand an overload of 100 per cent. for a minute or two), and, lastly, it must be impossible for it to get out of order, since the maximum that the meter records occurs only once in a year, and if the meter is out of order the opportunity is lost.

The Wright demand meter possesses all of these characteristics, and is simple as well as efficient. It consists of two sealed glass bulbs, connected by a U tube filled with colored liquid. The current passes through a coil wrapped around one bulb, the heat expands the air therein, and the air forces the liquid into the other bulb, out of which it is spilled into a closed tube. The greater the current the more liquid is forced up and spilled over. A scale is placed beside the closed tube and may be calibrated so that the height of the liquid spilled over shows the current in amperes or in kilowatts, or lamps, at a given voltage. The reading may be returned to zero by tipping up the glass tube and allowing the liquid to flow back. No allowance need be made for external temperature, since that affects the air in both bulbs equally. The instrument can be calibrated as accurately as desired. It is furnished in a strong iron case that can be locked or sealed against tampering. It cannot get out of order, since the only moving parts are the air and the liquid, and both are hermetically sealed in the glass bulbs and tubes. For the same reason it will never wear out. It will register slowly, approximately, 90 per cent. in 5 minutes, 95 per cent. in 10 minutes, 99 per cent. in 15 minutes, 100 per cent. in 30 minutes, thus being fair to the customer. It will always register 100 per cent., in which, as well as in its reliability and freedom from getting out of order, it has the advantage over any mechanical form.

In conclusion, it is enough to say that some twenty or thirty companies abroad are using the Wright system and have no idea of going back to any other, while hundreds of others are looking forward to adopting it. In fact, it may be said that thousands of companies, both in the United States and abroad, have practically adopted it, since the only reason for selling current for power cheaper than for light is that power customers are long-hour customers.

The first company to adopt this system was that at Brighton, in England, three years ago, and as a result of three years' use all of their 1,300 customers are thoroughly satisfied with the system and the company is to-day selling 50 per cent. more current in proportion to the plant used than it could on the ordinary system of charging. That means that without reducing expenses they can reduce the average price to about 75 per cent. of the former price, keep up the same rate of dividends, and have everything over the 75 per cent. as clear profit. There is no reason why every company in the United States should not make a similar gain.

CONTENTS.

ELECTRIC RAILWAY PROBLEMS.

It would be according small credit to the truly Herculean labors and energy of the large body of intelligent workers who have brought the electric railway art to its present condition, to assert that their efforts had gven us apparatus as far superior to that of ten years ago, as the modern bicycle is to the velocipede of fifty years ago. This is true as much of the electrical as of the mechanical constructions of electric car equipment; but with a full appreciation of what has been accomplished and the example furnished by the improvements of the past ten years, are we not warranted in looking for as great an advance at the end of the next decade? Even the most sanguine advocate of present methods would, we think, admit that improvement is not only possible, but desirable on lines which must be apparent to any one who has followed the course of events in this field.

Leaving out of consideration the minor improvements which time always brings with it, we would like to call attention to a few of the more important ones just at this time. It may be assuming a radical position to assert that gears and pinions must go, but we believe that that time is coming, and that it will be welcomed by all street railway managers. The cost of renewal of these parts of the present apparatus and the waste of power which their employment involves need not here be gone into, as it is a well known fact. That it has been realized is evidenced by the efforts which have already been made to bring about the substitution of other means of transmitting the power from motor to car axle without their intervention. We need only refer to the experiments made with hydraulic and similar devices, and also to the mounting of the motor armature directly on the car axle, but thus far none of these methods has made any perceptible headway in actual practice.

The suspension of the electric motor is another detail, which will bear additional study. For, in spite of the improved methods of this nature now employed, the fact remains that even with the heaviest rails employed the track shows the effects of pounding to an undue degree after but a comparatively short lapse of time. It would seem that some method were desirable for removing the weight of the motors from the car axles altogether, and its suspension from the truck frame entirely. This method has also been tried in a number of instances, but has not met with that success which the object to be attained calls for.

Perhaps many of the existing troubles experienced in trolley car operation, both mechanical and electrical, are traceable, if not entirely, at least in large part, to the continued use of two motors. In spite of the introduction of the multiple series controller the fact remains that the electrical efficiency of the motors is not commensurable with that which would be obtainable from a single motor operating under like conditions of change of load. It would lead us too far to enter into a discussion of the causes of the relative inefficiency of the two-motor arrangement and, indeed, they are too well known to need rehearsal at this late day. But, notwithstanding these unquestioned drawbacks, little has been done to introduce the obvious remedy. We believe that a one-motor equipment can be produced which will do all and more than the present two-motor, and that its advent will be hailed with delight by all railway companies now struggling to keep their rolling stock in running condition. We might continue in this strain and point out the desirability of being able to reverse suddenly without breaking anything, the need of mechanical brakes, and like advantages in other parts of the apparatus, but enough has been said, we think, to show that the individual or company that will bring about these and other improvements will not have to wait long for reward.

MYSTEROUS BREAKDOWNS IN INSULATION.

FROM the very beginning of electric lighting as an established industry the item of repairs has cut no inconsiderable figure in the accounts of central station and isolated plant operation. Later on with the introduction of the electric railway this factor in the operating expenses has in numerous cases swallowed up a good deal of the profits. Repairs of a mechanical nature will always be called for in machinery subjected to the hard usage that electrical machinery has always experienced, and due allowance must be made for the great ignorance still, unfortunately, existing and far too common among those placed in charge of electrical apparatus. But it is not to the mechanical repairs that we would here direct attention, but rather to the electrical, which, in spite of the vastly improved methods of construction employed, call annually for enormous amounts in the aggregate.

The weak spot still existing in electrical machinery is the insulation, and this refers as much to that of armatures and field magnets of generators and motors as it does to conductors, transformers and the like. It may be fairly assumed that competition among manufacturers has led to the employment of the best means of insulation known to the art, and hence the mishaps which still cause so much annoyance may be traced not so much to faulty or inferior construction as to other sources not usually considered, but which it is believed will have to be seriously looked after in the future. One of these causes can, we think, be directly traced to the present method of handling electric currents at the switchboard. The universal practice in the handling of electric currents is to effect the interruption or break in the shortest time in order to avoid destructive arcing, and the nearer this time has approached to instantaniety the more perfect the operation is considered to be. Where the currents to be handled are small this may not lead to any serious trouble, but it can readily be seen that where large currents are involved, such as is the daily practice in many electric light and railway stations, an element of danger is introduced which may in time cause serious trouble in the generating apparatus as well as in the conductors.

In the admirable paper on "Alternate Current Transformers," by Dr. J. A. Fleming, which was recently concluded in our columns, attention was drawn to this point more particularly in relation to its bearing and effect upon concentric alternating cables. Dr. Fleming showed that if a long cable of this character having considerable electrostatic capacity had the current suddenly "jumped" on it or interrupted, resonance effects might, under certain conditions, cause such a rise of potential as to pierce the insulation. One of the remedies for this particular case is to introduce some device into the circuit which will prevent the sudden rise of potential due to this cause.

We think that the warning sounded by Dr. Fleming is to a large extent also applicable to apparatus operating with direct current. It is hardly conceivable that generators or motors delivering currents of several hundred or even thousands of amperes can have their circuits interrupted without in time suffering from the strain put upon their insulation by the high induced electromotive force accompanying the interruption. It is true that it might be a difficult matter to trace the exact cause of failure in conductors or apparatus to this particular phenomenon, but that many of them are traceable to it is highly probable. The remedy for the evil is obvious. If, instead of breaking the circuit instantaneously, it could be effected gradually, though not necessarily occupying a space of time exceeding a second, the object would be accomplished. Such a method of circuit control would probably prevent the numerous "mysterious" failures of cables and puncturing of armature and field insulation which have begun to be looked upon as the work of kobolds, or as due to the inherent cussedness of electrical apparatus. Of course the means and apparatus required for such a method of breaking and making a circuit must not be too bulky or expensive for general application, and we know of no better field for exercise of inventive genius than the designing of such an arrangement.

TELEGRAPHIC STAGNATION.

THE annual report of the Western Union Telegraph Co., which is printed elsewhere in our columns, is a very interesting document to all electrical workers, and particularly to those directly engaged in the transmission of intelligence by wire. A great many inferences may be drawn from the statistics presented, but that which goes more directly to the vital point would teach us the cessation of growth in the telegraphic industry. Do the facts support the theory that any further expansion of the telegraph on a large scale is impossible? Does the telegraph in its growth fail to keep pace with the growth in wealth and population, and if so, why?

Turning to the figures, it is seen that although the number of messages declined in 1894 to 58,632,237, a falling off of about eight millions in one year, there has literally been no recovery since that time. This might be put down to the deep depression in business, but as the telephone has meanwhile been gaining enormously in use, the inference must be that to some extent the telephone has overlapped the telegraph, and, to use a yachting phrase, is persistently "blanketing" it. There is now barely one telegraph message annually per head of population. The number of telephone messages has reached about eleven per head. And even in crediting one per head for telegraphs, we have to add twelve millions at least to the Western Union figures as representing the share of the Postal Telegraph Company. It might be twice as much without materially affecting the comparison.

When it comes to carrying capacity, it will be admitted by all who know the facts that physically the Western Union system is well handled and is in a much better condition than when it was doing its great business of nearly 200,000 messages daily. But although rates have come down, operating expenses have not greatly yielded. Revenue per message is now, broadly stated, around 30 cents, where once it was nearly 40, but the cost per message fluctuates around 25 cents through a long period, and is now, after sharp retrenchment and vigilant economy, about 24 cents.

What can be done to rehabilitate the telegraph as the popular means of swift communication? It has been said that as there is no renewal of the old Western Union-American Bell agreement, the telephone lines will carry telegrams, and vice versa. In such an event the telegraph service would probably show up very advantageously, but we hardly look for that kind of warfare between the two great systems. What we do look for, and what we feel positively convinced must come, is a means of sending letter-telegrams, by machine methods, at a cheap rate, cutting into the incalculable field of mail matter between cities and accelerating correspondence by hours and days. But even that contingency is likely to be faced by other managers of the Western Union than those who have brought it through the late ordeal of business panic and industrial depression with the conservative prudence demanded more than any other quality by the situation.

THE ELECTRIC LIGHTING OUTLOOK.

ONE of the most extraordinary documents submitted lately to the attention of the electric lighting public is the annual report of the Anglo-Brush Co. (Brush Electrical Engineering Co., Ltd.), which coolly accounts for a poor year by intimating that there is no more electric light business to be had. The actual language is: "The directors regret that the profits of the year are not larger. The result is attributable partly to a general falling off in the volume of central station electricity supply contracts. . . . The directors anticipate, however, that the future demand for electrical traction plant will fully compensate for the shrinkage of orders for electric lighting machinery."

This is simply awful, and cannot be too sharply or strongly reprehended. The mere suggestion that England has all the electric lighting it wants or will ever get is so preposterous that even to mention the idea must provoke scorn and ridicule. To-day the electric lighting in England is still an insignificant fraction of the actual and possible illumination. The art has but begun its career, invention is young, the public interest has only recently been seriously aroused, and the numerous good qualities of the light are utterly unknown to the bulk of the nation. Even in America, where the adoption of the electric light has been far more general, it is universally felt that its adoption has but been inaugurated. We could not name a local company that has not plans of extension to be carried out when financial conditions are improved by the certainty of sound money, while new stations are being built all the time.

If the Anglo-Brush Co. is so soon tired and sees no future for electric lighting it had better clear out and make way for men of longer foresight and higher faith in their own products. As for the future of traction, whatever that may be in England, here at least it is certain that the needs for lighting apparatus will far outrun those for street railways. The railway companies are already supplying the public fairly well, while there is not a local lighting company to-day that could meet one-twentieth of the demand possible on it for electric light and power, and we say possible, because everybody prefers electricity to other agencies for the purpose. We are glad to know there is so good an outlook now for electric traction in England. It is certainly high time. But as to lighting, our advice to the Anglo-Brush people is to cheer up and hustle.

TELEPHONY AND TELEGRAPHY.

CHANGES IN THE NEW YORK TELEPHONE SYSTEM.

ONE reads a good deal in certain quarters about the movement of business uptown in New York. But the movement uptown is a trifle in comparison with the upward movement downtown. As a matter of fact business people seem to prefer to move up in the air, maintaining communication with the groundlings by means of express elevators, than to move out of the historic and natural downtown business district to the more airy part of the city where buildings are content with a modest eight or twelve stories. The large number of cloud-soaring office buildings which have shot up during the last few years below Chambers street, has materially increased the office capacity of the downtown district. This growth of business population has been accompanied by a rapid increase in the use of telephone service, and the advent of new subscribers has lately come within measurable distance of overtaking the capacity of the famous 5,100 line switchboard at Cortlandt street.

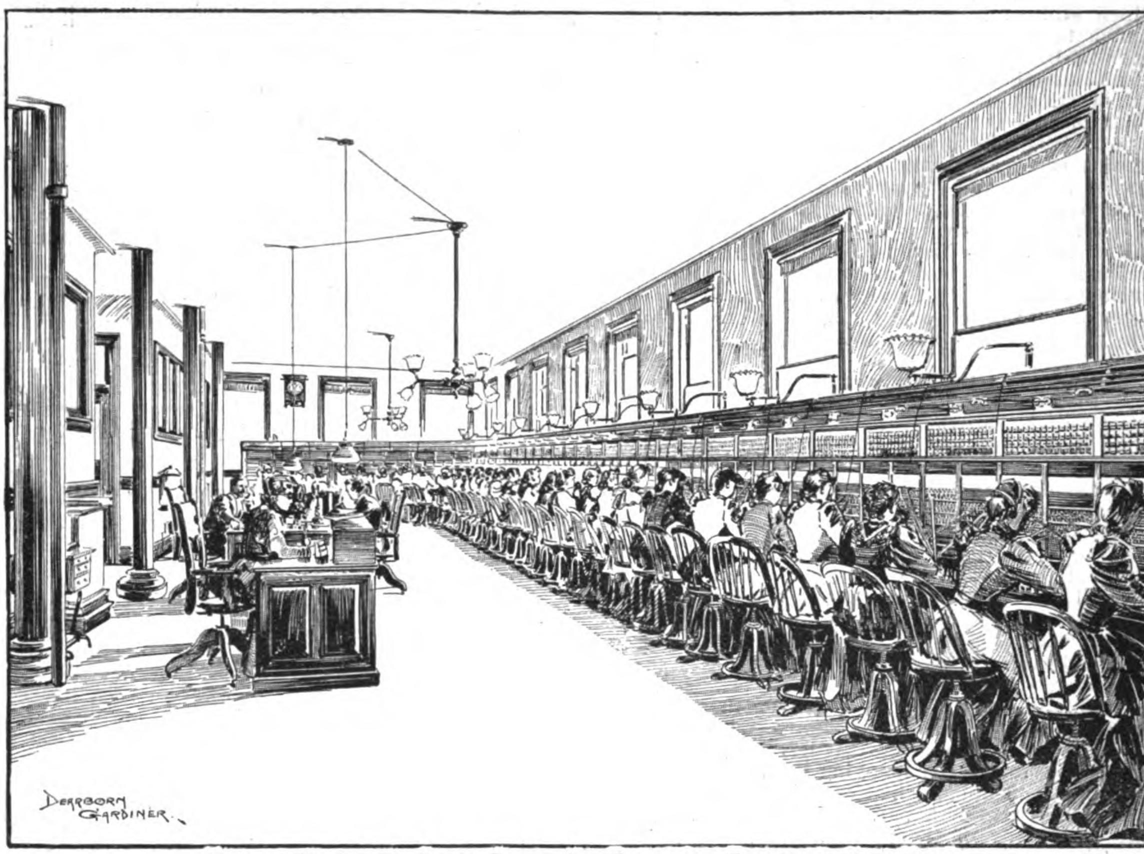
When this switchboard was first installed, some eight years ago, it took the place of four small exchanges, whose names are now but a memory, and served the whole of the downtown district south of a line drawn along Desbrosses street, Hudson street to Worth street, Worth to Division, Division to Rutgers, and Rutgers street to the East River (see Map 1.)

The general plan under which the New York telephone system has been rebuilt provided for two other downtown exchanges, the district of one—Broad street—to be taken entirely out of the Cortlandt street district and that of the other—Franklin street—to be taken partially out of the Cortlandt district and partly out of that of Spring street, which was formerly the next exchange north of Cortlandt.

The Broad street exchange was opened the first day of January, 1894. At that time about 4,000 subscribers were connected to the Cortlandt street switchboard. The new district comprised all the territory bounded by the east side of Broadway and Whitehall street to the Battery, and the south side of Wall street to the East River. (See Map 2.) This territory contained 1,050 subscribers' lines, which on the 31st day of December, 1893, were operated from Cortlandt street, and on the following day began to be operated from the new exchange at Broad street. This large removal gave Cortlandt a good breathing spell, the number of subscribers being reduced to about two-thirds the total capacity of the board. A still further reduction was made when the Franklin street exchange was opened a few months later, cutting off another slice of Cortlandt territory, and annexing some 350 Cortlandt subscribers.

Since these changes were made the message rate system of charging for telephone service came into play, and under its benign influence the increase of subscribers has gone on for the past two years at a greatly accelerated rate. So much so, that early in the spring of this year the number of lines operated at Cortlandt street was again considerably over 4,000, and progressing steadily upward.

In view of the growing density of the telephonic population of the Cortlandt street district and of the impracticability of increasing the capacity of the Cortlandt exchange except by building a new switchboard, a work not to be lightly undertaken in the present state of the switchboard art and in the present state of the Cortlandt street building, it was necessary to find an outlet for the stream of subscribers bent on carrying the largest New York exchange by assault. This was done with ease, if at considerable expense, by turning part of the Cortlandt street district into Broad street; in other words, by enlarging the Broad street district, and diminishing that of Cortlandt. The western boundary of the Broad street district has been extended from Broadway to the North River, and all the territory between those two lines and south of Exchange Alley and Morris street now belongs, telephonically speaking, to the Broad street exchange, instead of, as formerly, to Cortlandt. (See Map 3.) This takes some 250 subscribers out of the Cortlandt board and, of course, all new subscribers in the transferred district will be connected to the Broad street exchange.



VIEW OF OPERATING ROOM, BROAD ST. TELEPHONE EXCHANGE, NEW YORK.

The Broad street exchange was equipped with a bridging switchboard, designed for an ultimate capacity of 3,000 lines. The equipment actually completed at the time of opening provided for a total of 1,500 subscribers' lines, allowing for an increase of nearly 50 per cent. in subscribers over the number contained in the original district. During the two years and a half that the exchange has been in operation, the number of subscribers has increased from 1,050 to 1,350, so that in order to provide for the large addition of lines entailed by the transfer, it was necessary to increase the equipment of the switchboard. This has been done without adding new sections to the switchboard by means of converting two com-

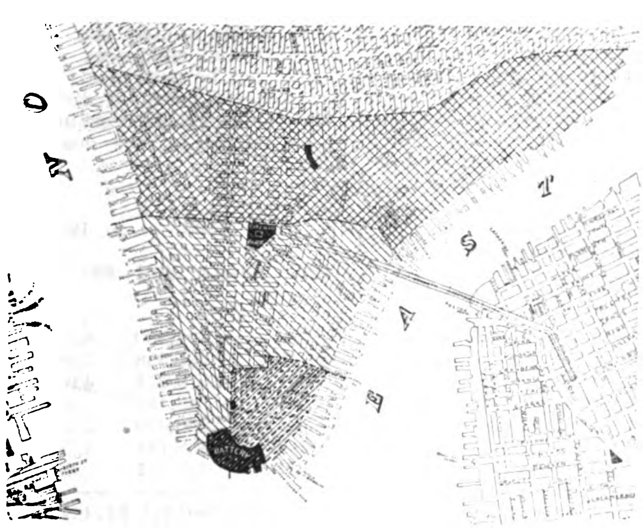
mon trunk sections into subscriber sections and by adding to the equipment of all the original subscriber sections.

The switchboard originally consisted of three incoming trunk sections with capacity for 270 incoming trunk lines, ten subscriber sections with 150 line drops and answering jacks, and three common trunk sections originally used for miscellaneous trunks and lines to the commercial exchanges. These latter

MAP 1.—ORIGINAL CORTLANDT ST. DISTRICT.

are now operated as regular subscriber lines, and the common trunks are consolidated at one section. The two common trunk sections thus left free have been converted into fully equipped subscriber sections of 195 drops each and 45 drops have been added to each of the original subscriber sections. This arrangement gives a board of twelve subscriber sections of 195 lines each. The total capacity of the board is now 2,340 subscribers' lines, being an increase of 840 lines over the original equipment.

The addition of the 840 drops and answering jacks was by no means all the work required to extend the capacity of the board. It goes without saying that to the original quota of 1,500 multiple jacks in each of the sixteen sections, 840 more had to be added. Further, the outgoing trunk equipment had to be increased by the addition of 120 outgoing trunk jacks to each subscriber section, keyboard apparatus to be added to certain sections and the capacity of the distributing board and protector plant to be enlarged. The work of fitting the



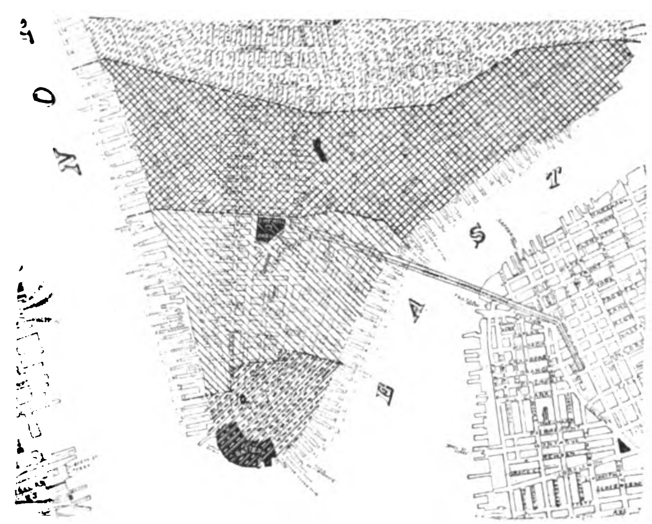
MAP 2.—FRANKLIN, CORTLANDT AND BROAD ST. DISTRICTS.

new apparatus, which included over 16,000 spring jacks, 780 self restoring drops, some 15,000 feet of cable and wire of different kinds and 840 sets of protectors and distributing board terminals, was carried out in accordance with the specifications of the engineer to the New York Telephone Company by the Western Electric Company, the builders of the switchboard.

So much for the inside work. But a large transfer of subscribers from one district to another involves a neat little problem in underground distribution and rearrangement of lines. This sort of arrangement has been met and coped with successfully several times before in the course of rebuilding the New York telephone system, and the Engineering Department of the New York Telephone Company, under the able direction of Mr. J. J. Carty, has become expert in solving it in any and all phases in which it may present itself. In the present instance the work has been much facilitated by the rapid progress made during the past year or two in the system of direct block distribution, devised by the company's engineer and carried out by the Construction Department. Under this system the main cables run out from the exchanges are designated feeder cables. From the points where these feeder cables terminate the distribution is carried out by means of distributing cables diminishing in size as the various subscribers' stations are supplied. It is scarcely necessary to point out that this method bears a strong family resemblance to distribution for electric lighting.

To serve the ten blocks comprised in the addition to the Broad street exchange four feeder cables, three of 100 pairs of conductors and one of 150 pairs, were laid from the Broad street exchange to different points for connection with the block distributing systems. These cables contain a total of 724,400 feet of twisted pair conductor. They afford provision for the 250 subscribers transferred, and for an increase of 200 subscribers in the district.

The transfer of subscribers from one exchange to another is effected by connecting all the lines to be transferred to the new feeder cables at the distributing points, the original lines being still left through to the old exchange. The lines in the



MAP 3.—FRANKLIN, CORTLANDT AND BROAD ST. DISTRICTS, SHOWING RECENT ENLARGEMENT OF BROAD AND DIMINUTION OF CORTLANDT.

new feeder cable are connected to their respective drops and answering jacks at the exchange end. Thus each subscriber is still working to his original exchange while there is bridged on to his line a completely equipped line to the new exchange. During the night appointed for the transfer the lines are put out of service at the old exchange and the connection is completed and the service taken up at the new. Thus, during Wednesday, September 30, some 250 subscribers were calling on Cortlandt for connections, and on Thursday morning, October 1, their calls were answered at Broad street. This change was effected without a hitch of any sort. It is much like changing from one completely furnished house to another equally thoroughly equipped and in running order, without the trouble of packing, moving and settling down,—an improvement in the ordeal of household affairs that every housekeeper would appreciate.

Writing of the Broad street telephone exchange calls to mind that in the beginning of its existence it was the scene of an interesting reception offered by the company to the subscribers whose lines were operated from the exchange. A special invitation was sent to each subscriber to attend a private view of the building and its electrical equipment, where the working of the exchange end of their telephone service might be advantageously inspected. A large number of Broad street subscribers attended the reception, and examined the apparatus, and watched the manœvres of the operators with undisguised interest and surprise. It was

evident that most of the visitors were quite unprepared to find that the equipment of a telephone exchange contained so much elaborate and highly finished apparatus, and that the work of answering calls and making connections required the unremitting attention of a numerous and well organized staff. Very many false impressions were corrected by that short visit to headquarters, and without exception the visitors departed with revised and improved opinions on telephone service.

The great improvement in the New York telephone service that has been brought about during recent years is due to several causes, which might all be summed up under the head of good management. To obtain good telephone service there are three requisites—a good plant, a well trained staff and intelligent co-operation on the part of the subscribers. The last can do wonders. New York is well off in all respects. The telephone plant of New York City is, to use a nautical phrase, well-found throughout. For completeness, for substantial, enduring material it is not equalled, scarcely approached by any large telephone system in the world.

Complete metallic circuit working, with long distance transmitters at every station are found nowhere but in New York. The staff of the New York Telephone Company has practically grown up with the system, and knows its work root and branch; there is scarcely any responsible officer of the company, from the president down, but has assisted in the complete rebuilding of the system, and has trained those under his direction to working under the new conditions and to the careful handling and operation of the new material. No staff could have better training. Lastly, much has been done toward the educating of the subscriber. By means both of the distribution of printed matter and by personal interviews the correct manner of handling the telephone and the few fundamental rules and practices of operating have been impressed on the subscriber in general. As a result the New York telephone service gives small ground for complaint; it is rapid, the talking is good, and interruptions are rare. Some complaint there must always be. It is not in human nature, nor in the nature of inanimate objects, that some 17,000 persons should co-operate through the medium of a vastly complicated system of wires and apparatus during every busy hour of every busy day without giving rise to a certain amount of friction. That the friction is as slight as it actually is, is vastly to the credit of the wires and apparatus and of the 17,000 co-operatives—subscribers and telephonists.

TELEPHOTIC PROBLEMS.—I.

BY EDWARD WAGEMAN.

IT is the prevalent opinion that with the transmission of light rays accomplished, the problem of telephoty has been solved. This is far from being the case. It gives us only a stepping stone upon which to build further facts. The combined light rays of the spectrum, constituting white light rays, are transmitted already, but the object appears only in white and dark outlines, and at its best as yet very unsatisfactorily. When experimenting with the transmission of colored light rays reflected from an object, the first difficulty encountered is the very fact that not the original light rays emitted from the source of light are available for transmission; the objects possess a certain unknown selective power with regard to certain different rays comprising the spectrum. The objects absorb some rays, others are refracted, and a certain number only are reflected to the transmitter, which selects some of the spectral rays and absorbs the same, transforming them into electrical impulses which form on the receiver the outlines of the object, as stated above. But what becomes of the rays from the colored surface of the object, and why are they not reproduced?

It appears that the element which is in chemical combination with the selenium will not respond to particular different wave lengths of the spectrum, but that it transmits and reproduces only the combined rays of the spectrum, and it is a question whether the effects appearing on the receiver are not due to the infra red end of the spectrum alone. It is evident that another element is needed in chemical combination with the selenium, which is either capable of instantaneously disintegrating the light rays transmitted by the other element in the proper places on the surfaces of the object in the receiver, or responding in the receiver as well as in the transmitter to distinct wave lengths of the spectrum, and must be instantaneous in its action. It will be seen that the possibility is disregarded of telephoty being feasible in some mirrorlike action.

The selection of this other third element will necessitate many hundred carefully executed experiments as the necessary data regarding the qualities demanded are wanting or incomplete, and must be made in daylight as well as with every known and employed source of illumination, as it is well known that the indices of absorption, reflection and reproduction will change with every source of illumination, and one must be selected of nearly uniform index in all kinds of illumination.

FIGURES FROM THE WESTERN UNION ANNUAL REPORT.

THE annual report of the Western Union Telegraph Company for the fiscal year ended June 30 shows gross earnings of $22,612,736, the largest gross since 1893, but net earnings of only $5,897,980, a decrease of $243,409 from the net of last year. This showing is partially explained by the table of comparative costs per message, which shows that during the year the average cost reached 24 cents, or more than any year since 1885; while a similar table shows that the average tolls per message were only 30.9 cents, a rate than which only three years in the company's history have been lower. The following table from the report shows comparisons in detail:

	Miles of wire.	Messages (000 omitted).	Receipts.	Profits.
1885	462,283	42,096	$17,706,833	$5,700,924
1886	489,607	43,289	16,298,638	3,919,855
1887	524,641	47,394	17,191,909	4,037,281
1888	616,248	51,463	19,711,164	5,070,571
1889	647,697	54,108	20,783,194	6,218,041
1890	678,997	55,878	22,387,028	7,312,725
1891	715,591	59,148	23,034,326	6,605,584
1892	739,105	62,387	23,706,404	7,398,547
1893	769,201	66,591	24,978,442	7,496,037
1894	790,792	58,632	21,852,655	5,792,484
1895	802,651	58,307	22,218,019	6,141,389
1896	826,929	58,760	22,612,736	5,897,980

President Eckert says in part:

"The table shows an increase of 453,129 messages. But by an analysis of our reports we find that we transmitted and delivered about 920,000 more full-paid messages than we transmitted and delivered during the year ended June 30, 1895. The difference between these two sums is accounted for by a decrease in the number of press, government, signal, and sundry other messages. The decrease in the number of press messages arose from the great depression of business and from the transfer of service to wires newly leased from us, thereby taking it out of the count of messages handled by our employés.

"The increase in operating and general expenses was caused partly by the necessary expenses for establishing the additional 365 offices that were opened in various localities during the year, and partly by the outlay for operators and messengers' salaries and for incidental expenses in handling and delivering the increased number of full-paid messages shown above.

"The increase in the cost of maintenance and reconstruction of lines was caused by an unusual number of destructive storms, especially the cyclone at St. Louis, and by work that, with a proper regard for the stability and efficiencey of the lines upon which it was done, could not be postponed."

At the meeting of stockholders, the old board of directors was re-elected, and Roswell G. Holston and E. H. Perkins, jr., were chosen to fill the vacancies caused by the death of Austin Corbin and George Bliss.

The balance sheet is as follows:

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—V.

BY LIEUT. B. A. FISKE, U. S. N.

THE STEERING TELEGRAPH.

THE office of this instrument is to telegraph from certain places in a ship to the steering wheels, the position at which it is desired to put the helm. This is accomplished by means of certain apparatus, called transmitters, placed where desired and electrically connected to indicators secured in conspicuous positions near the steering wheels. The principle on which the system depends is the same as that on which the helm indicator depends, the transmitters consisting of strips of resistance wire, through which currents of electricity are passing and over which traveling contacts are moved by an operator, while the indicators are galvanometers connected electrically to these contacts.

Fig. 7 is a diagram of electrical connections for a steering telegraph system, comprising three transmitters, shown on the upper part of the page, and two indicators shown on the lower part of the page.

The resistance wires, a a', are traversed by currents of electricity, furnished by any suitable source, such as a storage battery, primary battery, dynamotor, etc.; in Fig. 7 the source is the electric light mains of the ship, a suitable resistance being interposed, as shown, to reduce the current in each transmitter to about 2 amperes. The passage of a current of electricity through the resistance wire of any transmitter, such as the second transmitter shown in Fig. 7, is immediately due to a difference in electric pressure, or potential, between different parts of the wire; so that the permanent metallic contact, G, and the traveling contact, C, are at different pressures or potentials. If the current is flowing in the direction represented by the arrow-heads, contact, C, is at a higher potential than G, so that a current of electricity will pass through any galvanometer connected to them, going in the direction from C to G, and move the galvanometer needle to the left. If, on the other hand, C were to the right of G, it would be at a lower potential and the current through a galvanometer connected to C and G would go in the direction from G to C and move the galvanometer needle to the right. If the contact, C, were at the middle part of the wire and rested on G, C and G would be at the same potential and the galvanometer needle would remain at rest in the middle of the scale.

In order that two or more transmitters may be connected independently, and yet be so adapted that any one transmitter may be used at any time, the contact, C, and the wire, G, are so arranged that the contact, C, does not touch the wire when it is in its middle position. So long, therefore, as the contact, C, of any transmitter is in its middle position, that transmitter is not connected to a galvanometer and does not affect any galvanometer or any other of the transmitters. In the position shown in Fig. 7, the movements of contact, C, of the second transmitter affect the galvanomters just as though the first and third transmitters were absent. When not in use, the contact of each transmitter should be placed in its middle position, not touching the resistance wire. This caution is marked on each transmitter case. The amount of the movement of contact, C, may be shown on a graduated scale and the resistance in the circuit so adjusted and the galvanometers so marked that the galvanometer needles will point to the figure that indicates the movement of the contact, C. This method is like that adopted in the helm indicator, but a preferred method is that shown in Fig. 7, because the system is not affected by any changes of electro-motive force of the generator, and the work of adjusting the resistance is avoided. By the plan shown in Fig. 7, there is placed in front of each transmitter a galvanometer exactly similar to the galvanometers which act as idicators at the steering wheels. The operator, then, at any transmitter, moves his contact until the galvanometer in front of him points to the desired helm position—say, 20 degrees port; and the two indicators at the steering wheels will instantly show 20 degrees port.

A further advantage of the use of this galvanometer at the transmitter is that the operator always knows by its movements whether or not the apparatus is working.

In the absolute apparatus, as ordinarily constructed, the resistance wire, a a' is wound in a spiral groove on the circumference of a cylinder, D, of insulating material, such as rubber, as indicated in Fig. 8. The two ends of the wire are connected to flat springs, a a', against which press the ends of the binding posts, A, B. The permanent contact, G, is connected by a short pin to a metallic ring, R, placed at one end of the cylinder; and a flat spring, P, connected to the binding post, E, continuously presses on the ring, R. At the point where the permanent contact, G, is connected to the wire, the groove in the cylinder is cut down deep into the cylinder, so that the contact, C, cannot touch it. To accomplish this, in constructing the apparatus, the cylinder, D, is cut in half transversely, and the contact, G, after being soldered to the

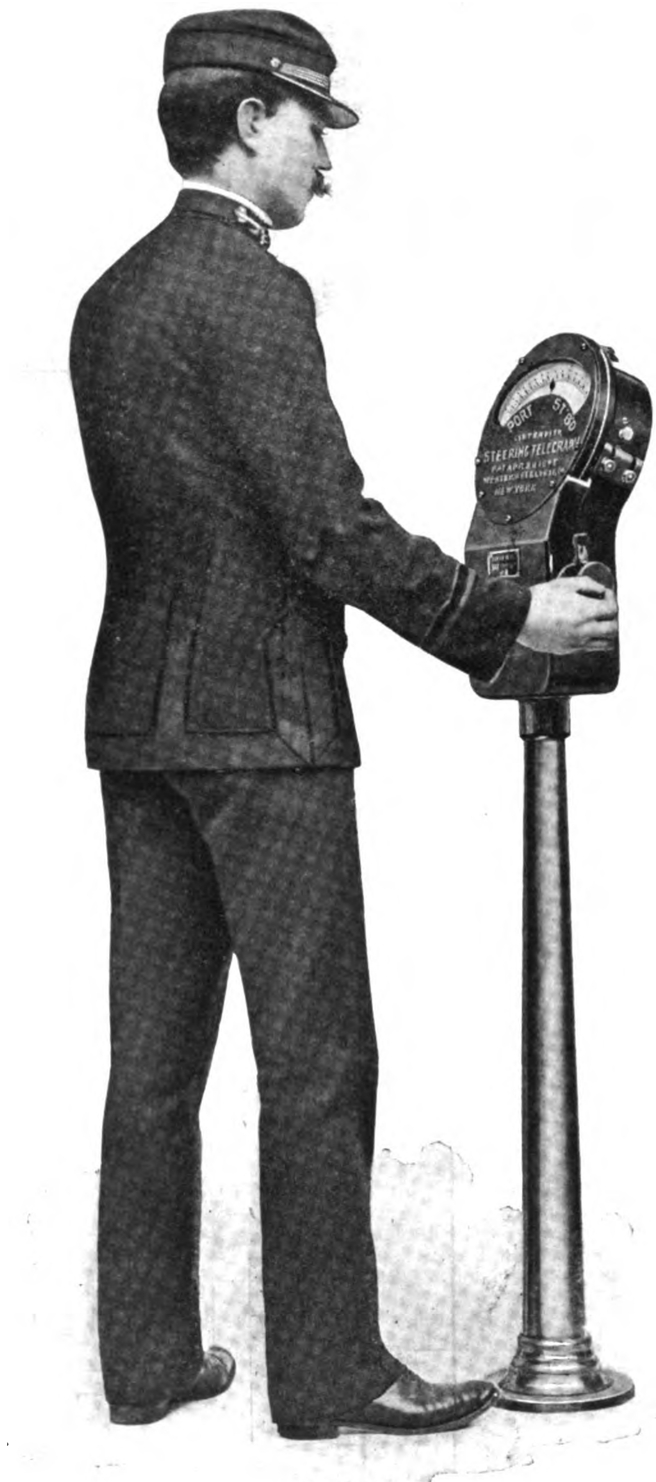

FIG. 8A.—ELECTRIC STEERING TELEGRAPH.

wire which is to be wound on the cylinder, is secured in position. Then the two halves of the cylinder are screwed together and the wire is wound in the groove. To produce movement of the contact, C, it is mounted on the nut, N, which travels on the screw, S, C being insulated from N. The pitch of the screw, S, and of the spiral thread in the cylinder, D, are the same, so that, as S is revolved by turning the handle, H (thereby turning D by means of the gear wheels shown), the nut, N, is moved along the screw, S, and the contact, C,

along the wire, a a', the contact always remaining in the groove that holds the wire.

The copper wires connecting the instruments should not be less in size than No. 16 American gauge.

The transmitters of the steering telegraph are so arranged that any transmitter can be used independently of any of the others and produce the corresponding deflections in all the galvanometers, both of the transmitters and receivers, so long as both of the other transmitters are secured carefully at zero; but any movement of any transmitter while another is in use is indicated immediately by the erratic movements of all the galvanometers. In order to show clearly when a transmitter is at zero, a glass is placed in its face through which the sliding contact can be seen. When the transmitter is at zero the reference mark on the sliding contact is directly in line with the zero mark in the transmitter; and it can be secured in this position by means of a stout pawl which falls into a slot cut in the handle, H, Fig. 8.

The steering telegraph was given a year's test in sea service on board the U. S. S. New York, and the test having passed successfully, the apparatus has since been installed in the U. S. battleships Indiana and Massachusetts, using in each ship three transmitters and two indicators. It is now being installed in the Texas, and is to be installed in the Brooklyn.

Weight of indicator, 22 pounds.
Resistance of indicator, 60 ohms.
Weight of transmitter box, 6 pounds.
Diameter of indicator, 10 inches.

UTILIZATION OF CULM.[1]

BY N. W. PERRY.

As illustrating the relative economies of gaseous and electrical transmissions, the late Mr. Denny Lane, an English gas engineer of prominence, once stated that, with ordinary 16 candle-power gas, 3,000 horse-power could be sent a distance of one mile for an expenditure of 1 horse-power—an economy of distribution far exceeding that possessed by any other system, being only 0.03 per cent. of the power conveyed.

With respect to the cost of mains, he says, taking the cost of conductors laid on the low-pressure culvert system at £5,500 per mile for the conveyance of 1,080 amperes, and assuming an electromotive force of 110 volts, the power would be 158 horse-power. It would, therefore, require, he says, two pairs of these conductors to convey 300 horse-power, while a 6-inch main, with ordinary gas, would convey sufficient gas for that power at 4-inch pressure, and at 16-inch pressure would deliver as much as four pairs of such conductors. The 6-inch main, he says further, would cost £500 per mile, while two pairs of low-pressure conductors would cost £11,000, and four pairs would involve an expenditure of £22,000 per mile.

The lecturer has found, by calculation, that to transmit this power to the distance named, at 220 volts, the metal in the pipes would cost considerably less than the metal in the conductors. Contrast this with electrical transmission, in which 10 per cent., or 300 horse-power would be an allowable loss, and we see how the gas transmission has the advantage over the electrical.

I also find that a 6-inch pipe will deliver 6,000 cubic feet of illuminating gas per hour at a distance of 10,500 feet, under 4 inches of water pressure. If this be 16 horse-power gas, and be used in a gas engine, allowing 25 cubic feet per horse-power hour, this quantity represents 240 horse-power.

Cast-iron pipe, 6 inches in diameter, having a thickness of ½ inch, weighs 31.9 lbs. per foot. The total weight of this two miles (nearly) of pipe will, therefore, be 334,950 lbs. This would be equivalent in conductivity to about 41,869 lbs. of copper equally distributed over the same distance. But four miles of copper, weighing 41,869 lbs., would be equivalent to about four No. 000 B. and S. wires, which would have a resistance for the four miles of 0.325 ohm. If the charging current was transmitted at 220 volts there would be required a current of 848 amperes; but a wire having a resistance of .325 ohm will only deliver under a pressure of 220 volts, $220 \div .325 = 677$ amperes; there would, therefore, be required five No. 000 B. & S. wires to deliver this energy, and the weight of this would be 53,540 lbs.

If the distribution took place at 1,000 volts, the amperes required would be approximately 180. To deliver this at the same distance with a loss of 10 per cent. would require 6,264 lbs. of copper, and to deliver it at 1 per cent. loss would require 62,642 lbs., which would cost far more than the pipe, and still give less efficient transmission.

When the fuel is delivered in this form it is adaptable to all of the uses to which fuel is ever applied. It can be burned under boilers for the raising of steam for power or heat purposes, or it can be applied to domestic uses, or it may be used directly to advantage in gas engines. In no case need there be any stand-by losses, such as are inevitable with solid fuels, for when the fires are wanted it is only necessary to turn on the gas, and when they are no longer needed it may be turned off, and there are no ashes or coal to be handled.

For power purposes a somewhat extensive investigation of the question has satisfied me that, if we can procure cheap gaseous fuel, the gas engine is the proper thing to use, especially in situations such as are found in our electric lighting stations and elsewhere, where the load is variable between wide limits.

In such situations a portion of the boiler plant must lie idle during the hours of light load, and it has been estimated by very competent authorities that the consumption of coal of the idle boiler amounts to 10 per cent. of the total consumption of all the boilers.

With the gas generator the stand-by losses are so small as to be negligible in comparison, so that a direct gain in economy is here attained.

I believe that all of the English gas-engine manufacturers will guarantee their engines, even in comparatively small sizes, to produce a brake-horse-power-hour, when using Dowson gas, on 1¼ lbs. of anthracite coal or less. It is seldom that our largest compound condensing steam engines are found to give equally good results.

In view of these facts there are many who believe that the problem of utilizing the culm accumulations is to be solved by the conversion of this culm into cheap fuel gas at the banks, and its transmission thence in pipes to the point of consumption, or to the centers of distribution by other more convenient means.

I believe, although I have not attacked this problem from the numerical side, that it would be economical to pipe this artificial gas to Philadelphia from the nearer coal fields. I know, however, that it would be more economical for your electric lighting and power companies to convert their fuel into gas on the water front, and distribute it thence in pipes to gas engines favorably located as to distribution, than to cart their coal to these centers, pay rent or interest on the investments required for boiler and coal storage room, and other attendant expenses.

[1] Abstract of a lecture delivered before the Franklin Institute.

RULE FOR ESTIMATING THE POWER FACTOR IN THE COST OF CARBIDE OF CALCIUM.

BY LIEUT. F. JARVIS PATTEN.

If we assume an output of carbide of four-tenths pound per horse-power at furnace terminals, about 6 per cent. more than shown in the Spray tests, and assume steam power at New York to cost $45 per horse-power year of 6,000 hours, then steam will cost three-quarters of a cent per horse-power hour. It would, therefore, require 2,000 or 5,000 horse-power hours to make one ton of carbide. Adding 20 per cent. for unavoidable losses, this would be 6,000=600 horse-power continuously operative to produce one ton of carbide in ten hours. This at three-quarter cent per horse-power is 4,500 cents, or $45, would be the cost of power required to make one ton, which would be the assumed price of one horse-power per year above. Therefore, under these assumptions, the cost of power for producing one ton of carbide is the same as the price of one horse-power per year.

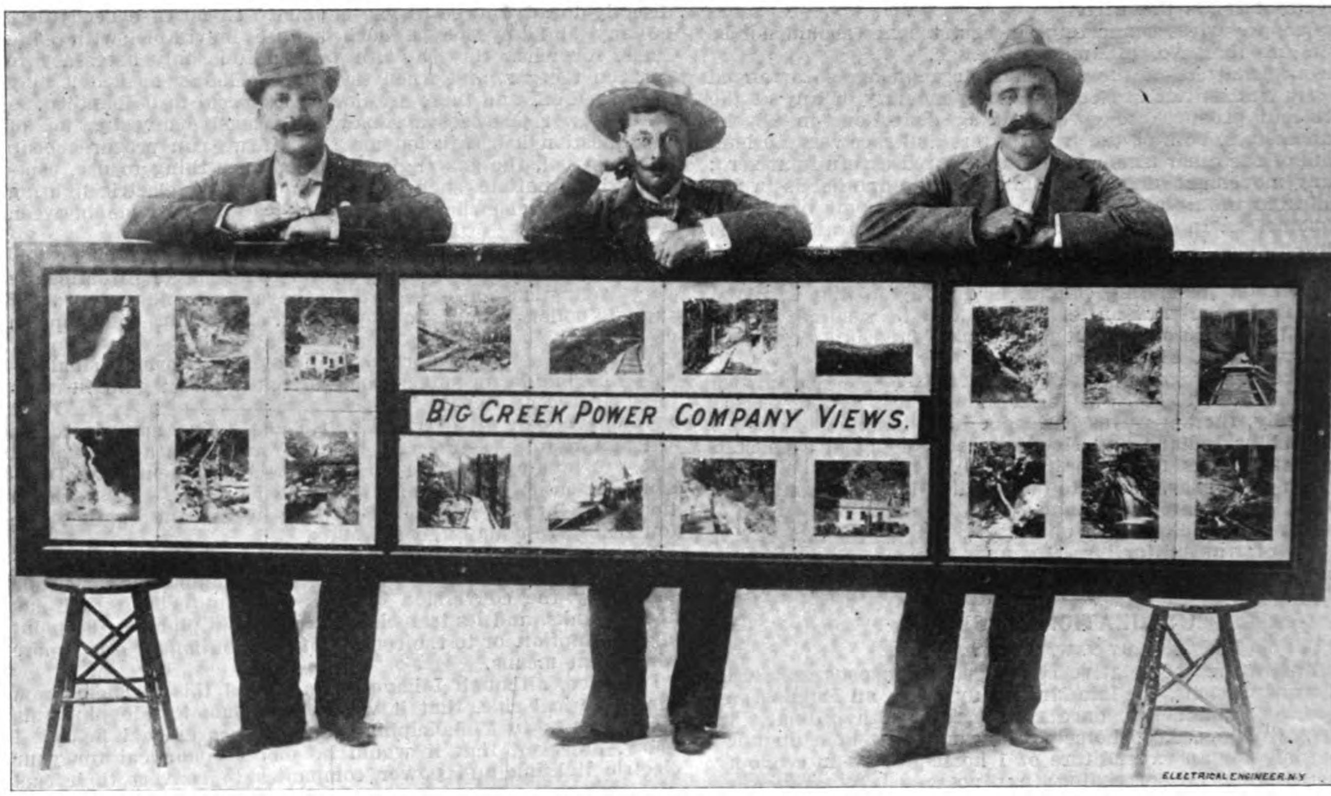
So, if water power costs $5 per horse-power per year, then the power factor in the cost of carbide is $5 per ton.

To find the actual cost of carbide we have to add the cost of lime and coke and labor; excluding the labor factor we may proceed as follows: It takes 0.875 ton of lime and 0.5625 ton of coke to produce a ton of carbide, hence the rule: Multiply the cost of lime per ton in dollars by 0.875, and the cost of coke per ton in dollars by 0.56 and add to their sum the cost of horse-power per year in dollars; the sum is the cost of a ton of carbide exclusive of labor, interest, depreciation, etc.

Example: Coke = $2.75 a ton.
Lime = $2.50 a ton.
1 horse-power = $5 per year

then $(0.875 \times 2.50) + (0.56 \times 2.75) + 5.00 = \$9.72$.

Another simple calculation based upon the same assumption of 0.4 pound per horse-power hour indicates a ready answer to the question, how many tons of carbide can be produced daily with a given steam or water power? The answer is that since the rate is 0.4 pound per horse-power hour, it is also one ton per horse-power year of 6,000 working hours. Hence the rule, any power as 5,000 horse-power continuously operative should produce 5,000 tons of carbide a year. These rather remarkable coincidences of figures offer, therefore, a ready rule of thumb system of calculation and remain true until new discoveries or improvements shall operate to reduce the power factor which is, of course, the principal one.—"Progressive Age."



VIEWS OF POWER HOUSE AND FLUME, BIG CREEK POWER CO., SANTA CRUZ, CALIFORNIA.

POWER TRANSMISSION.

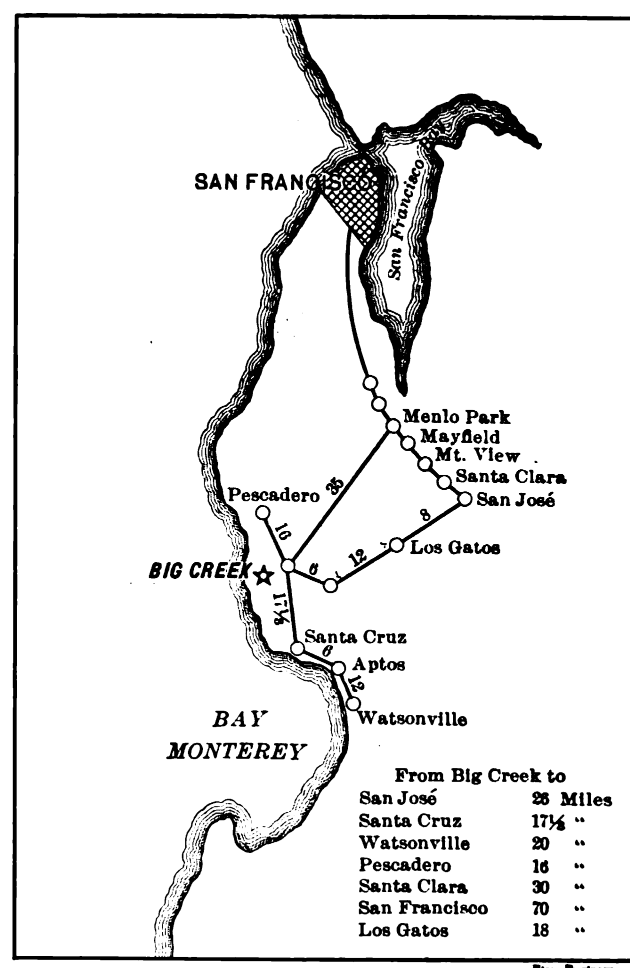
THE BIG CREEK, CAL., POWER TRANSMISSION.

IN the year 1889 Santa Cruz, Cal., saw the completion of its first incandescent light station. This work was the result of the labors of Mr. F. W. Swanton, who, with the success of the electric light plant assured, next proceeded to the organizing and building of the Santa Cruz Electric Railroad. The power for the railroad was furnished from the electric light station. During a period of six years the fuel bill for the combined electric light and railway power station rose to the enormous figure of $60,000, owing to the high price of coal in that region, and hence came the desire for a cheaper source of power than could be produced by steam. Mr. Swanton did not have far to look, and soon had secured possession of Big Creek from its mouth to the top of the mountain, thus securing control of the best water power in the country and the one having the greatest fall.

The minimum power available from this creek under existing conditions is 500 h. p., but a site has already been secured for an impounding reservoir which will increase the minimum capacity to 1,000 h. p. all the year round. At present the creek has an available capacity of 2,500 h. p. for eight months in the year.

The plant works under a head of 923 feet, to obtain which was constructed a wooden flume, 11,125 feet long and having a depth of 18 inches and a width of 30 inches. The flume was built of one-inch redwood boards doubled with lapped joints. From the penstock the water is carried for 1,930 feet of leaded and banded joint pipe of the following dimensions, beginning with the penstock and continuing towards the power house: 965 feet of 16-inch No. 12 iron pipe; 370 feet of 14-inch No. 10 steel pipe; 200 feet of 14-inch No. 8 steel pipe; 200 feet of 14-inch No. 6 steel pipe; 200 feet of 14-inch No. 5 steel pipe.

The power house is a small temporary wooden structure, containing at present a 46-inch Pelton wheel having a capacity of 500 h. p. at 600 revolutions per minute. The wheel is designed to operate one 150 kilowatt generator on each side. At present but one such generator has been installed, and this is a Westinghouse two-phase machine, operating at 1,100 volts. From the switchboard the 1,100 volt current is conveyed to two 75 kilowatt self-cooling transformers, by means of which the potential is raised for transmission purposes to



MAP SHOWING BIG CREEK, CAL., AND SURROUNDING TERRITORY.

from 10,000 to 11,000 volts, according to load, and at the same time transformed into 3-phase current by the Scott system. Round redwood poles are used on the transmission line. These poles are thirty feet long, are set approximately forty to the mile, and each carries two cross arms, the top one being a four-pin and the lower a two-pin arm, thus providing for two 3-phase circuits.

The wires consist of No. 5 B. & S. gauge bare copper wire, which are transposed at every pole. Immediately below the lower cross arm is carried the telephone circuit, which is strung on brackets and transposed every fifth pole, and conversation is carried on between the power house and the substation, a distance of seventeen and one-third miles, with ease.

The sub-station, which is located on the ground floor of the Pilot Building, in Santa Cruz, contains transformer and switchboard equipments practically identical with those at the power house, and in addition the switchboard carries panels of four two-wire distributing circuits of from 1,000 to 1,100 volts.

The entire output of the Big Creek Power Company is at present sold in bulk to the Santa Cruz Electric Light and Power Company. The Big Creek Power Company has recently placed an order with the Westinghouse company for the duplication of the plant above described, which will give a total of 400 h. p. in generator capacity at the power station. These two 2-phase generators are to operate in parallel supplying current to a common circuit, and the generators are to be coupled direct to the water wheel by means of specially constructed friction clutches.

The accompanying map shows that the company are in a situation to command a large field for power. They expect eventually to operate the railway system, and also the city lighting and pumping plant, and also motors for manufacturing and other purposes.

The reproduction of a photograph, which appears on page 402, gives a number of views showing construction of the pipe line, power house and other details of construction. The three gentlemen leaning on the frame were the most prominently active in the carrying out of the work. Mr. F. L. Robinson, who appears on the left, is the president of the company; the gentleman in the center is Mr. F. W. Swanton, to whom is due the inception of the scheme, the location of the water power and the financiering of the enterprise; and at the right is Mr. C. E. Lilly, the electrical engineer.

As regards the financial outlook for the company, it may be of interest to note that it started off by paying 18 per cent. on its investment with its first contract.

PRESENT STATUS OF THE DISTRIBUTION AND TRANSMISSION OF ELECTRICAL ENERGY.—III.

(Concluded.)

BY DR. LOUIS DUNCAN.

POSSIBLE VOLTAGES AND DISTANCES OF TRANSMISSION.

A number of calculations have been made as to the possibility of transmitting electrical energy to very long distances. If the question of cost of transmission alone is considered, then where water powers or culm heaps are within distances of 100 miles of some large center of consumption, it has been shown that it would be profitable to generate and transmit electrical energy. In these calculations, however, voltages are assumed that have never been employed for commercial plants, and whose availability is problematic, while sufficient stress is not apparently laid on the question of the reliability of the power. If the industries of a large city depended upon a single transmission plant, it is evident that the question of reliability is of paramount importance. Where energy is supplied to manufacturers, to street car systems, and for lighting, a break down that would involve the cutting off of current for a day would mean an enormous pecuniary loss to the community. As the distance of transmission increases, the possibility of accident is increased in greater ratio because we have not only the higher voltage to control but the length of the line that must be looked out for is also increased. The best guide lies in the practical experience which has been obtained in the present transmission plants and the consideration of the difficulties that have arisen and the remedies that have been employed. I have prepared a partial list of the principal transmission plants that are now in operation.

It will be seen that the longest transmission is at Fresno, Cal., the distance being about 35 miles. The highest alternating voltage used is 13,000 volts at Zurich, Switzerland. The highest direct potential is 15,000 volts at Brescia.

All of these plants are working successfully, and this fact will lead to still longer transmission and higher voltages. No limit of either distance or potential has as yet been reached. If we consider the record of the present transmission plants, we can safely say that it would not be going outside of the safe limit of development to transmit at least 50 miles at a potential of 20,000 volts, provided the energy could be delivered at such a price as to be considerably lower than the cost of a corresponding amount of energy obtained from a steam plant. This, of course, is a matter of local condition entirely, and the commercial value of such a transmission will depend upon local conditions.

LONG DISTANCE TRANSMISSION FOR RAILROAD WORK.

The possibility of long distance electric railroad lines is intimately connected with the possibility of long distance transmission of power. We have seen that it is possible to transmit considerable distances from a single station. The current so distributed is not, however, such that it can be applied directly to railroad motors, but it must be transformed at points along the line, the distance apart of these points of distribution depending upon the system that is employed. At present continuous current motors are used and considerations of safety would lead us to use line potentials not greater than 700 volts. By distributing rotary transformers at distances of five or six miles apart, we would be able to supply motors with current without any great investment in copper. The amount of copper required could be still further reduced by using rotary transformers with storage batteries, thus keeping a constant load on the transmission line. It will be found, however, that on any long distance railroad line, the load on any section of the line is exceedingly variable and the discharge rate of the batteries will have to be very high in order to prevent excessive cost for our reducing stations. It is doubtful whether we have reached a point in battery construction that this system of transmission would be economical. It is certain, however, that when the distances are comparatively short, say within 15 miles, and where the traffic is not evenly distributed, that rotary transformers, with or without batteries, can be economically employed for railroad work.

CONCLUSIONS.

My conclusions, subject always to the influence of local conditions, are as follows:

1. In both direct current lighting and traction systems, where the power is generated in or near the area of distribution, it is best to use one station situated at the most economical point for producing power.

2. In the case of the traction systems, when the economical area of direct distribution is passed, boosters should be employed directly or in connection with batteries, to a distance of ten or twelve miles from a station, and beyond this rotary

transformers, whether with or without batteries, should be used.

3. In the case of direct current lighting systems, the energy should be transmitted to storage batteries situated at centers of consumption either directly or by means of a rotary transformers and distributed from them.

4. Where batteries are used it is best to place them at the end of feeder wires to obtain the advantage of a constant load on the wire.

5. The best system for the long distance transmission of energy, for general purposes, is the three-phase alternating system.

6. Commercial transmissions are in successful operation for distances of 35 miles, and for voltages as high as 15,000 volts.

Experience with these plants shows that the transmission to 50 miles with a pressure of 20,000 volts is practicable, beyond these limits the transmission would be more or less experimental.

Roentgen Rays.

THOMSON X-RAY INDUCTORIUM AND DOUBLE-FOCUS TUBE.

IMMEDIATELY upon the first announcement of Prof. Röntgen's experiments, Prof. Elihu Thomson took up the subject with his characteristic energy, and soon succeeded in developing a type of apparatus specially adapted for carrying on X-ray experiments. The results of his experiments

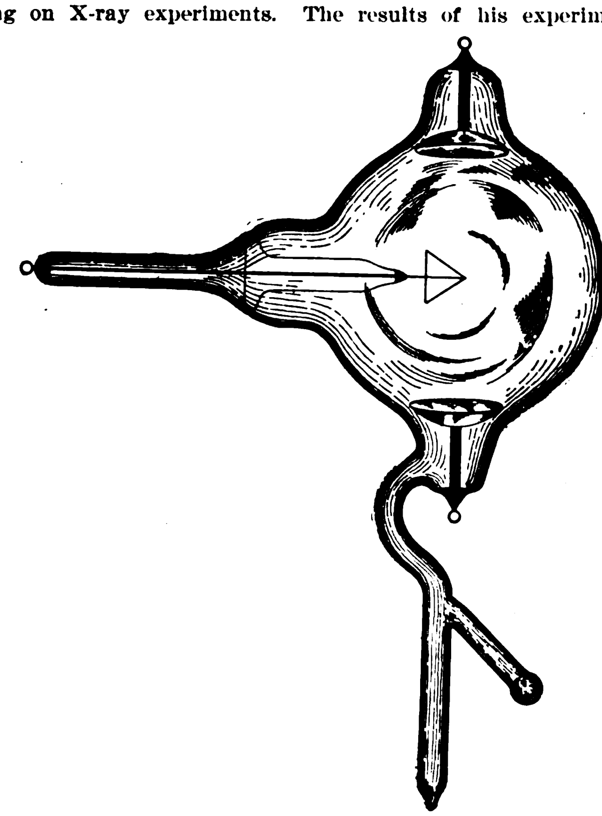

Fig. 3.—Thomson Double Focus X-Ray Tube.

have now been made available to the public in the X-ray apparatus manufactured by the Edison Decorative and Miniature Lamp Department of the General Electric Co., at Harrison, N. J.

Our engraving Fig. 1 shows one form of the Thomson inductorium capable of giving a constant stream of 6-inch sparks. In addition to the thorough insulation of the coil itself, the highest practical degree of insulation is obtained by placing the coil in a box filled with oil, Fig. 2. The contact breaker which goes with the inductorium is a rotary one, operated by a small motor, and is so constructed that the break occurs under water, so as to reduce the sparking unavoidable with the breaking in air.

A similar type of apparatus is made to give a 12-inch spark.

Prof. Thomson has also designed a Röntgen ray transformer, adapted to be run from alternating circuits. It consists of a low frequency and a high frequency transformer together with a condenser. On account of its high frequency and its practically unlimited supply, it makes a very powerful exciting apparatus.

Fig. 3 represents the Thomson universal double focus tube, which has been largely introduced in this country, as well as abroad. The two cathode electrodes are cup-shaped, and made of aluminum. The other electrode is a wedge-shaped

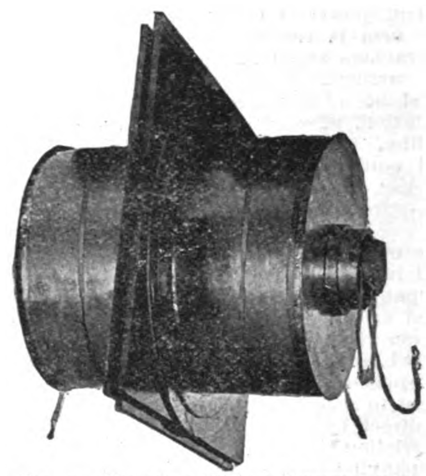

Fig. 1.—Thomson X-Ray Inductorium.

piece of platinum upon which the rays are focused. The sharpness of definition obtained by this form of tube is well known. The failing of the tube, owing to the increase of the evauum, has been provided against by the attachment of a

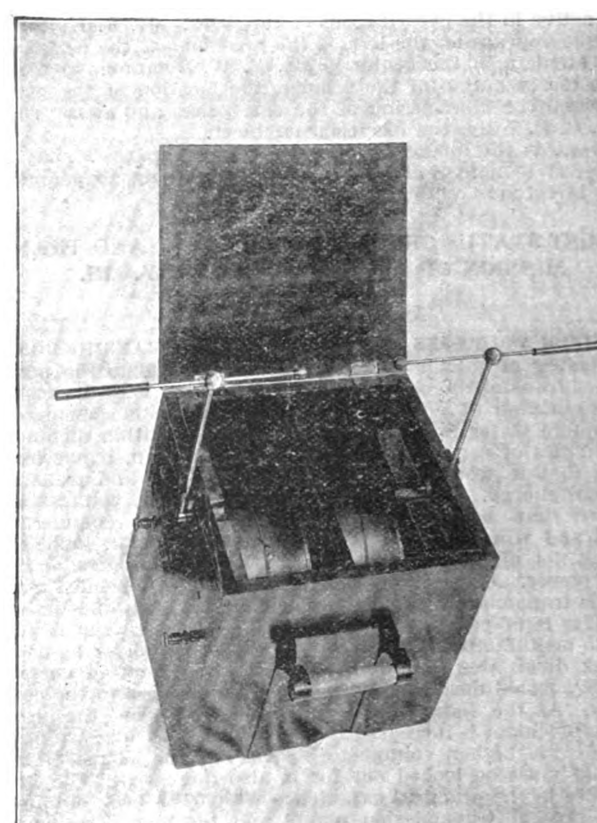

Fig. 2.—Thomson X-Ray Inductorium.

small auxiliary tube containing a chemical mixture. When the later is heated it gives off a vapor, which on entering the main tube brings down the vacuum to the proper point.

Another adjunct to an X-ray set is a diaphragm for shielding, which cuts of all stray rays and permits only those emanating from the platinum electrode to reach the fluorescent screen or photographic plate. In this way perfect sharpness of image is secured.

ROENTGEN RAYS AT THE BRITISH ASSOCIATION MEETING.

WE print below abstracts of a number of papers devoted to the Röntgen ray, read before the recent meeting of the British Association, at Liverpool.

Prof. Lenard read a paper on "Cathode Rays." After briefly sketching an outline of his well-known researches, he passed on to a statement of his views of the nature of cathode and Röntgen rays. Here he came into collision with the views of English physicists who were present, and thereby kindled the fire of an interesting but rather one-sided debate. All the English physicists who took part—Sir George Stokes, Prof. Fitzgerald and Prof. J. J. Thomson—stated unqualifiedly views opposed to those advanced by Lenard.

In a speech, lasting over one hour, Sir George Stokes gave an historical and critical account of the controversy. In the first place, he observed that although the cathode rays fell upon one side of an aluminum window, and were diffused from the other side, it did not necessarily follow that they actually passed through the thickness of the aluminum. He conceived that the action which was transmitted through the metal in such a case was not in the nature of a cathode ray, but bore to the cathode ray a relation which was analogous to the relation which the passage of ions of copper in an electrolytic copper salt bore to the dissolution and deposition of metallic copper at the anode and cathode. He believed the cathode ray to be a thing quite distinct in its nature from the Röntgen ray, and the confusion between them which had arisen from the similarity or identity of some of their properties he considered to have been brought about by the difficulty in completely separating the two classes of radiation. The cathode ray he regarded as a stream of electrified material particles, while the Röntgen ray he believed to be ethereal.

The next paper was one by Prof. J. J. Thomson and E. Rutherford, dealing with "The Laws of Conduction of Electricity Through Gases Exposed to Röntgen Rays." This dealt with the continuation of the researches on the effect of Röntgen rays upon the conductivity of matter, and the surprising result has been arrived at that the passage of these rays through a gas or vapor deprives it of its insulating properties, during a period extending some time beyond the cessation of the passage of the rays. Moreover, the temporary conductivity or pseudo-conductivity thus set up in a gas may be immediately destroyed, and the insulating properties be restored by the passage of an electric current through the modified gas. Obviously, then, the influence of the rays is opposed by the influence which the current will exert which they permit to flow through the gas, so that at that point at which the opposing influences are equal the maximum possible current through the gas has been attained. Thus this maximum is found to depend, not on the electromotive force causing the current, but on the intensity of the stream of Röntgen rays which passes through the gas and modifies its properties.

In a paper which followed Prof. A. W. Rücker described how Röntgen rays might be used for distinguishing between various qualities of porcelain, those containing phosphatic china being opaque relatively to those porcelains of which this substance is not an ingredient.

Dr. Trouton read a paper on "The Duration of X-Radiation at Each Spark." He found the duration to be sometimes only $\frac{1}{10000}$th of a second, sometimes as long as $\frac{1}{800}$th of a second, and that the duration varied in a very erratic manner. He stated that the duration seemed to depend on the kind of photographic paper used, and on other factors. Prof. J. J. Thomson remarked that radiation so brief showed how inefficient was a spark coil as an instrument for producing it, since the period of the spark was so much longer than the period of the radiation. He himself proposed to use a replenisher and a very high voltage battery for producing the discharge in a focus tube or other Röntgen ray apparatus.

A paper was read by Prof. S. P. Thompson on "The Relation Between Cathode Rays, X-rays, and Becquerel's Rays." Prof. Thompson showed that the shadow of an object within the tube projected by cathode rays on the glass behaved differently from the shadow of that same object projected upon a fluorescent screen outside of and some distance from the glass bulb. When the object was electrified, the cathode shadow on the glass expanded or contracted very markedly, according to the sign of the electrification, whereas no such movement was observable in the shadow on the fluorescent screen, the production of which was due to Röntgen radiation. Prof. Thompson stated that he had observed no image or shadow on the glass at the point where the trajectory of the Röntgen ray shadow passed through the glass.

Prof. Bjerknes attacked the view that the "magnetic spectrum" of the cathode rays, viz., the assortment of the various rays by their deviation in a magnetic field, is a continuous spectrum. He described some recent researches of Prof. Birkeland, of Christiania, which tended to show that this magnetic spectrum is discontinuous, and is broken up into a number of separate lines or patches, after the manner of the luminous spectra of gases. This effect Prof. Bjerknes considered to be inconsistent with the molecular hypothesis of the cathode ray, and he thought it supported the theory of ether waves. Prof. J. J. Thomson elicited the information that the gas in the tube was of a composite nature, and also that no less than 40 distinct lines of cathode rays had been detected at times in the magnetic spectrum.

"Hyper-Phosphorescence," the subject of a paper by Prof. S. P. Thompson, was regarded by Sir George Stokes as tending to support his new theory of non-periodic disturbances. Glow worms, it transpired, exhibit hyper-phosphorescence, and a member of the association who had experimented with the glow of these curious creatures asserted his belief that they "hyper-phosphoresce," even while they do not glow. Prof. Thompson thought that the eye of the glow worm, constructed as it is, independently of refraction, might be a hyper-phosphorescent, or Röntgen ray organ.

LETTERS TO THE EDITOR.

HOW TO PUSH FOR LOCAL LIGHTING BUSINESS.

We beg to call your attention to the inclosed advertisement which is appearing daily in the leading Boston papers. In calling to your attention this advertisement we beg to submit to your consideration the following points:

First—We believe that this is the first time that one of the leading local lighting companies has extensively advertised their current for sale and is a departure from the conservative policy hitherto in vogue with such companies.

Second—It has become a well recognized fact that the Welsbach Gas Burners are more economical for a given illumination than the incandescent lamps, and while the quality of the Welsbach lighting may not be as satisfactory as that of incandescent lighting, the fact that it is a cheaper illuminant results in the use of Welsbach Burners by a good many persons who would otherwise use electricity.

Third—The Welsbach Company have been doing a great deal of advertising and have succeeded in displacing many thousands of incandescents, thus reducing the current output of electric lighting stations throughout the country.

In view of these facts, this move upon the part of the Edison Electric Illuminating Company of Boston, is a direct attack upon the Welsbach interests, and is, therefore, worthy of comment in your paper, for by the general use of Manhattan arc lamps they have found it possible to give their customers a greater and more satisfactory illumination than can be secured by the Welsbach Burners, and at a much smaller cost.

We deem this a matter of sufficient importance to your readers to call your attention to these facts for use as you see fit.

ROBB MACKIE,
Secretary Manhattan Gen'l Cons. Co.

New York City, Oct. 15, 1896.

(The "ad" is an excellent picture of the Manhattan lamp, and calls attention to its local use in a well known hall. Other local companies might well follow suit.—Eds. E. E.)

SOCIETY AND CLUB NOTES.

THE NEW YORK ELECTRICAL SOCIETY.

Owing to the inclemency of the weather the meeting of the society announced for last Tuesday was postponed. Due notice will be given of the new date.

PERSONAL.

MR. H. C. ADAMS, JR., having been elected secretary of the Phillips Insulated Wire Conmpany, will hereafter make his headquarters at Pawtucket, R. I., and their New York office, at 39 Cortlandt street, will be closed. Mr. Adams will have charge of the sales department, and will visit the trade as heretofore,

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Central Stations:

CENTRAL STATION ECONOMIES.—By Arthur V. Abbott, C. E., and Franz J. Dommerque, M. E. This article is one of a series and contains a good deal of information, carefully arranged in form of tables. The various headings in one issue are: Fuel Gas. Analysis of Natural Gas, Use, Consumption. Composition of Illuminating Coal Gas; Amount Yielded per ton of Coal; Cost and Relative Cost of Gas and Coal per 1,000 B. T. U. Efficiency of Producers; Composition of Various Producer Gases; Determination of Calorific Value of Gas by Weight, etc. Wood; Average Composition of Wood; Fuel Coefficients for Wood; Composition of Charcoal; Yield of Charcoal, etc.—"Elec. Eng'ing," Oct., 1896.

ELECTRICITY AT COPENHAGEN.—A 200 K. W. Station, run on the three-way plan, two systems at 110 volts for lighting and two for power at 220 volts. Four compound condensing engines, five dynamos, two of four poles furnishing 240 volts and 135 volts at 730 rev. run by one engine and three dynamos of 4 poles each yielding 280 amperes at 490 rev. Two accumulator batteries, consisting of 70 cells each with a capacity of 800 ampere hours. Wiring has a total length of 35 kilometres and consists of underground cables, naked copper wire in tunnels and aerial conductors.—"L'Industrie Electr." and "West. Elec.," Oct. 3, 1896.

SOME CONTINENTAL ELECTRIC LIGHTING STATISTICS.—By F. Ross. Data on the yearly burning times. Several tables in "Elektrotechn. Zeitschrift," Sept. 10, 1896. Abstracted in Lond. "Elec.," Sept. 25, 1896.

ELECTRICAL WORKS "KAISERSLAUTERN."—By Oskar von Miller. Detailed report showing a net profit in one year of over $2,000.—"Die Elektrizität," Sept. 19, 1896.

Electro-Chemistry:

OZONIZED WATER.—According to the Philadelphia "Telegraph" Pepin, of Paris, the well konwn chemist has invented a process of purifying water by electrically introducing ozone, —"Mail and Expr.," Oct. 3, 1896.

IRON SMELTING BY ELECTRICITY.—Dr. G. de Laval and Robsohn, of Stockholm, have obtained from the Swedish Government a concession for the establishment of a company for the smelting of ores in electric furnaces on a large scale.—Lond. "Elec.," Sept. 25, 1896. "Elec. Engr.," Oct. 14, 1896.

APPLIED ELECTRO CHEMISTRY.—By James Swinburne. A Cantor lecture. After some general remarks on the seat of e. m. f. in a cell and on dissociation, author explained for the first time the Ashcroft process for treating the argentiferous sulphide of lead and zinc in the Broken Hill mines.—Lond. "Elec.," Sept. 25, 1896.

Measurements:

RHEOSTENE.—By Dr. J. A. Harker and A. Davidson. A new alloy of iron and nickel, proposed for cheap resistance frames.—Note in Lond. "Elec.," Sept. 25, 1896.

Mechanical:

THE VERTICAL ENGINE FOR STATIONARY PURPOSES.—By Charles H. Manning, U. S. N. Author explains the development of this type of engine and believes in its more general adoption on account of many advantages which are also herein enumerated.—"Cassier's Mag.," Oct., 1896.

BROWN GAS AND GASOLINE ENGINE.—Description of this engine for which the following advantages are claimed: Possibility of changing from gas to gasoline without stopping the engine; avoidance of compression and the making of the electric spark only when needed; possibility of changing speed while engine is in motion and the running of the engine over or under.—"Iron Trade Rev.," Oct. 1, 1896.

AN ELECTRIC DREDGER.—The current for this dredger may be generated on the shore and conveyed to the motor by means of overhead wires or cables. High tension is being used. A 45 H. P. motor is attached to the buckets.—"Scientif. Am. Supplem.," Oct. 3, 1896.

NOTES ON ELECTRIC CRANES.—By E. W. Anderson. Read before the British Assoc. A summary of the relative advantages of the various methods of adapting motors to cranes, and a comparison of electricity with other sources of power, such as hydraulic, steam or rope gear transmission. —Paper in full in Lond. "Elec.," Sept. 25, 1896.

SNAP LIMIT SWITCH OF THE SPRAGUE ELECTRIC ELEVATOR.—An illustration and description of a new automatic snap switch to prevent overwinding.—"Am. Mach.," Oct. 8, 1896.

Mining:

ELECTRIC MINING MACHINERY.—By Irving Hale. Author gives some suggestions as to handling of mining machinery electrically, such as pumps, hoists, drills, etc.—"Elec. Rev.," Oct. 7, 1896.

Roentgen Rays:

THEORIES.—During the discussion on this subject before the British Assoc., the English physicists held that the Röntgen ray is essentially different from the cathode ray, while the German physicists (Lenard and others) believe in the hypothesis of ether waves. Sir Geo. Stokes mentioned that a non-periodic ether disturbance might explain the phenomenon. (The London "Electrician" says that Sir G. Stokes "trotted out this brand new theory"; it is not by any means a new theory, for Dr. M. J. Pupin mentioned this in May last and based it at the time on one of Helmholtz's latest papers. Ed.)—Lond. "Elec.," Sept. 25, 1896, "Elec. Engr.," Oct. 21, 1896.

DURATION OF X-RADIATION AT EACH SPARK.—By Dr. F. T. Trouton. He found the duration sometimes to be only $\frac{1}{10,000}$th of a second sometimes as long as $\frac{1}{250}$th of a second.—Note in Lond. "Elec.," Sept. 25, 1896, "Elec. Engr.," Oct. 21, 1896.

SHORTENING TIME OF EXPOSURE.—Messrs. Eder and Valenta have failed to shorten exposures by using orthochromatic plates, but have shortened it by heating to 50° C. or by a screen of fluoride of calcium, used with a silver bromide and celluloid film.—Note in Lond. "Elec.," Sept. 25, 1895.

SEEING THE RAYS.—G. Brandes found that X-rays could be seen if the crystalline lens were removed from the eye. All the humors of the eye are more or less opaque to them.—From the "Beiblätter," Lond. "Elec.," Sept. 25, 1896.

ON CATHODE RAYS.—By P. Lenard. Read before the Brit. Assoc. An account of his principal experiments in the properties of cathode rays outside the generating tube—Short abstract in Lond. "Elec.," Sept. 25, 1896.

ON THE TRANSPARENCY OF GLASS AND PORCELAIN TO THE ROENTGEN RAYS.—By A. W. Rücker, F. R. S., and W. Watson. Read before the British Assoc. Those kinds containing phosphatic china are relatively opaque to those of which this substance is not an ingredient—Abstract in Lond. "Elec.," Sept. 25, 1896.

Railways:

ELECTRICITY IN CLEANING CITY STREETS.—Description of a self-loading car for removing dirt and refuse from the streets. This car is 50 feet long, 9 feet wide, 12 feet high and is supported on double trucks. It is claimed that all the principal streets of a city may be cleaned between the hours of midnight and 5 a. m. with all the sweepings removed from the city by railway at a cost not exceeding $2 per mile.—"West. Elec.," Oct. 3, 1896.

Storage Batteries:

GERMAN AND FRENCH ACCUMULATORS.—Two new types of accumulators, the W. A. Böse and the "shuttle," are described in "West. Elec.," Oct. 3, 1896.

Telephony, Telegraphy, etc:

AN ELECTRIC TELEGRAPH WITHOUT ANY LINE.—A Danish invention is recorded, the invention of P. Sörensen, principally as follows: An electric battery is placed on the shore. One pole is in contact with the water or moist earth, while the current from the other pole, through a telegraph key and a revolving interrupter, is conducted to a cable, which is laid out to the anchor ground and placed around the latter in a coil with a diameter of 1,000 to 2,000 feet. On board the ship there is a small solenoid to which the telephone is connected.—"Elec. Rev.," Oct. 7, 1896.

ELECTRICAL DISTURBANCES IN SUBMARINE CABLE.—By W. H. Preece, F. R. S. Paper read before the British Assoc. Section A. Author explained some peculiar forms of disturbance on new cables.—Lond. "Elec.," Sept. 25, 1896, "Elec. Engr.," Oct. 14, 1896.

Power Transmission:

PRESENT STATUS OF THE DISTRIBUTION AND TRANSMISSION OF ELECTRICAL ENERGY.—By Louis Duncan, Ph. D. Paper read before the Amer. Inst. of Elec. Eng's., Sept. 23, 1896. Speaker reviewed the principal methods of transmission and distribution now in vogue. Although stating no new features of any sort, the paper forms an excellent résumé of the position which electrical transmission and distribution now occupies.—"Elec. Rev.," Oct. 7, 1896, "Elec. Engr.," Oct. 7, et seq.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

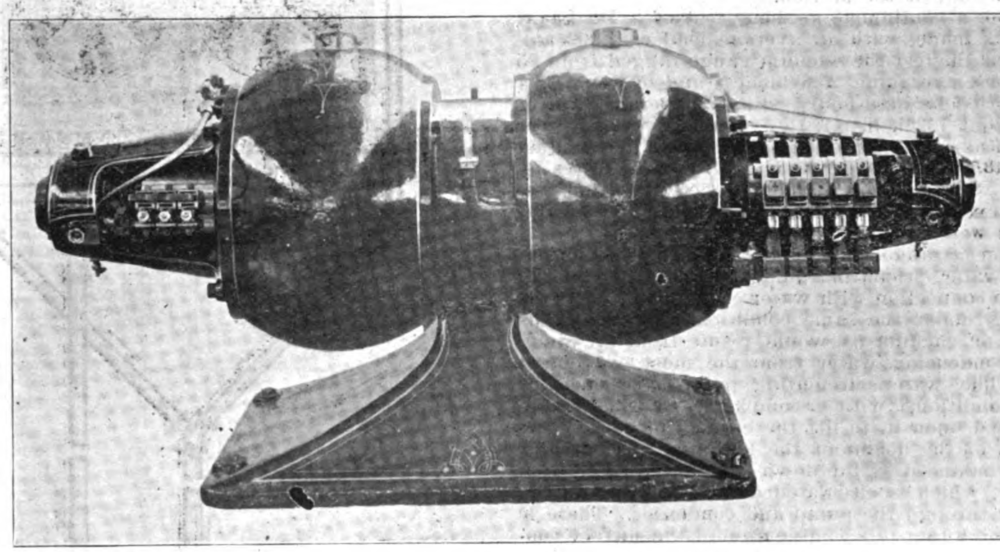
SHULTZ BELTING CO.

President J. A. J. Shultz, of the Shultz Belting Co., of St. Louis, writes us that one of the latest of the large trolley plants belted up by them was that of the Missouri Electric Railway Co., of Webb City, Mo. It took several twenty-eight-inch belts. Mr. Shultz expects a brisk revival in business later on, and, knowing the electrical field intimately, stands well to secure his share.

THE BOOSTERS IN THE CONGRESSIONAL LIBRARY WASHINGTON.

IN our last issue we printed an illustrated description of the electric lighting plant in the new Congressional Library at Washington. One of the features of this plant is a series of five boosters, which were made necessary by the great length of the feeders, some of which are 600 feet long.

These boosters, one of which is illustrated in the accompanying engraving, were built by the Northern Electrical Manufacturing Co., of Madison, Wis., and their object is to keep the potential constant at the centers of distribution. Each booster consists of a motor dynamo combination on one shaft, the motor being run direct off the bus bars and the dynamo being in series with the feeders. This latter arrangement, adopted by Dr. Cary T. Hutchinson, consulting electrical engineer for the government, is a departure from the usual practice of connecting the booster to the bus bars, and presents the advantage of effecting the necessary change in condition gradually, thus preventing flickering in the lamps. These boosters raise the potential from 6 to 12 volts at the feeder ends, depending upon the current load.



NORTHERN BOOSTER IN NEW CONGRESSIONAL LIBRARY, WASHINGTON.

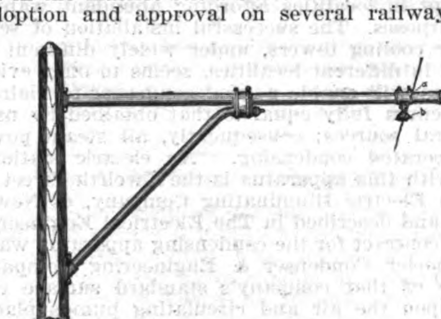
THE EXCELSIOR RAILWAY BRACKET.

The Excelsior Railway Bracket has been placed on the market by the John Simmons Company, No. 110 Centre street, New York, with a view to supplying a bracket as simple and durable as possible. To this end bolts have been discarded, because vibration loosens the nuts and eventually the bolt itself; cast iron has ever been condemned, as it will crack in severe weather; screwed angle joints were replaced with an elastic band, because of the saving of labor, assembling and erecting.

The "Excelsior" bracket is fitted throughout with malleable iron fittings. The joint of the curved brace and the arm consists of a sleeve around both pipes, which are about 1¼ inch apart. Between the pipes are two filling pieces ⅜ inch thick, closing the open space between pipes, and made into one casting by a longitudinal rib. When the set-screws bear upon the arm, the whole joint becomes rigid, but still remains so elastic that the screws are not affected by vibration.

There has, however, another important advantage been kept in view. Loosening screws and withdrawing the filling piece, enables one to bring the curve of the brace clear through the sleeve without removing either flange or acorn. Thus, by bringing brace and arm into parallel position the bulk of the bracket is reduced to a minimum of space for shipping and carting. The flexibility of this bracket is as obvious as its strength and lightness.

Though in the market but a short time, the "Excelsior" has found adoption and approval on several railways of recent construction. Sizes and lengths are variable, and all requirements can be met, no matter what they be. The manufacturers of this bracket also carry steam and electrical engineering supplies, iron pipe, standard and extra heavy fittings and valves, and have the facilities of the largest pipe-cutting establishment in New York.



THE EXCELSIOR RAILWAY BRACKET.

ZIEGLER ELECTRIC CO.

A handsome and important catalogue has been issued by the Ziegler Electric Company of Boston, which, from dealing chiefly in school and educational apparatus, has grown into one of the leading makers and dealers in supplies and instruments and is now one of the powers in the land. The present book of 200 large pages, carefully illustrated, deals specifically with their electrical trade, and embraces measuring and testing instruments, bells, batteries, lamps, generators, motors, shades, resistances, telegraph appliances, switches, wire, etc. Sizes, number and prices are given in detail. Another catalogue issued by the house from their headquarters, at 141 Franklin street, Boston, is devoted exclusively to physical, chemical and scientific apparatus and material.

CONSOLIDATED INSULATED TUBE CO.

The Consolidated Insulated Tube Company, John Hancock Building, Boston, inform us that they have purchased all the rights, title and interest, together with machinery and patents of the Builders' Insulating Tube Company, of Lynn, Mass., and the Kinney Electric Conduit Company, of Boston, and that they will manufacture a full line of plain and armored tubing for interior and underground wiring. They will endeavor to make the best goods and to effect prompt shipments.

MR. JOHN F. OUTWATER, representative of Hugo Reisinger, New York, was in Chicago on a business trip last week.

THE BARNARD WATER COOLING TOWER FOR ELECTRICAL STATIONS.

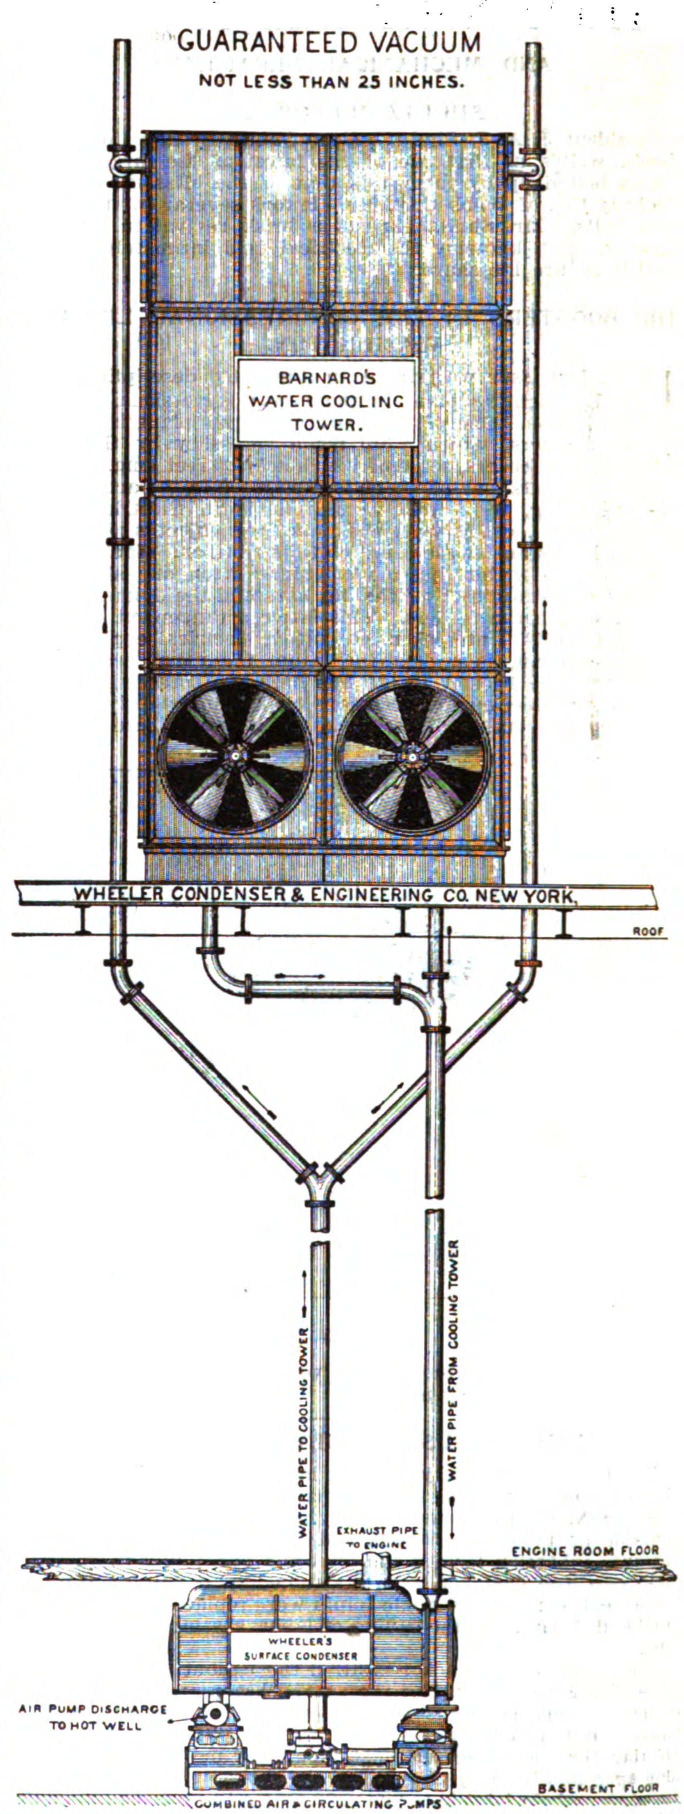
THE use of multiple cylinder condensing engines, requiring from 1¼ to 2 pounds of coal per indicated horse-power per hour, according to size, has, until recently, been prohibitory, except in localities affording abundant water for condensing purposes. The successful installation of several Barnard water cooling towers, under widely different conditions of use and in different localities, seems to offer evidence that these towers will enable a good condenser to maintain a degree of vacuum fully equal to that obtained by using water from natural sources; consequently, all steam power plants may be operated condensing. An electric station recently equipped with this apparatus is the Twelfth Street station of the Edison Electric Illuminating Company, of New York, as illustrated and described in The Electrical Engineer of Jan. 8, 1896. The contract for the condensing apparatus was awarded to the Wheeler Condenser & Engineering Company. It included one of that company's standard surface condensers, mounted upon the air and circulating pumps placed in the basement, and a Barnard water cooling tower located on the roof, which is some 70 feet above the condenser. The up discharge pipe from the top of the condenser conveys the hot water to the top of the tower, and the pipe from the bottom of the tower conducts the cooled water down to and through the circulating pump and condenser to the up pipe. This water is kept in continuous circulation through the channels above described, and, sufficiently cooled in its transit through the tower to enable the condenser to maintain 25 inches vacuum, or better.

The apparatus works smoothly and quietly. To see it in operation and the work it accomplishes, one would be more inclined to believe the injection water came from a river 10 feet below the condenser, rather than from a small tank 70 feet above, and on the roof of the station.

On April 2, 1896, a continuous six-hour test of a De Laval steam turbine was made, with an average load of 1,402 amperes. Throughout the test the vacuum gauge ranged from 25 inches to 26 inches, averaging 25.6 inches; and on Sept. 2 a full load was carried for five hours, with an average load of 3,628 amperes (about 732 i. h. p.); the vacuum averaged over 25 inches. It will also be of interest to state that the exhaust steam averaged 13,535 pounds per hour, and that the losses by evaporation, etc., were only 3 per cent. of the circulating water, and did not exceed 80 per cent. of the boiler feed-water when the engines were working condensing.

The combination arrangement of the Wheeler condenser, with its air and water circulating pumps, is particularly well adapted for use in connection with water cooling towers, as the air pump operates under the same conditions and maintains the same degree of vacuum as would result from an abundant supply of condensing water from the most convenient natural source. The water circulating pump also operates under ordinary conditions, with a comparatively small additional duty imposed upon it, to lift the circulating water possibly 25 per cent. of the height of the building. The greater part of the lift is balanced by the down column of water from the cooling tower, which is circulated down one pipe and up the other, passing through the pump and condenser. There is not a building so high that this combination of the surface condenser in the basement, and the cooling tower on the roof, is not usable, as the apparatus is wholly independent of distance, either horizontally or vertically. Roof structures are largely a necessary in cities, but where ground room is available, the cooling tower may be situated at any convenient point.

The Barnard cooling towers are continuously efficient, as they are subjected to no wear or oxidation, the superficial surfaces being steel wire cloth (galvanized after weaving), made in mats and suspended in a vertical position, properly placed. The hot water from the condenser is evenly subdivided and distributed over the upper edges of the mats, uniformly flowing over and through them, compelling every square foot of the mats to do a proportionate amount of work. The space occupied by the tower is small, and the power required to operate is estimated at from 2 per cent. to possibly 5 per cent. of the main engines, according to conditions.



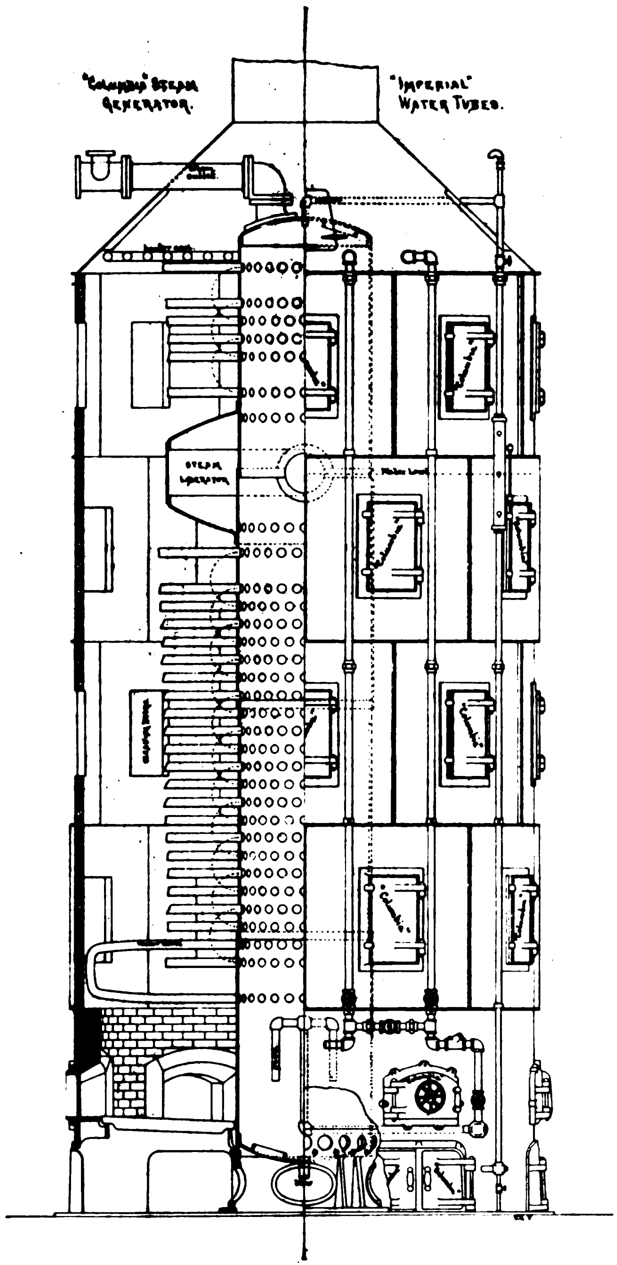
COMBINED BARNARD WATER COOLING TOWER AND WHEELER CONDENSER.

MR. JOHN LYNCH, formerly State Agent for the Universal Electric Company, Cleveland, O., has recently received a similar appointment to represent J. C. Wormley & Co., of the Marquette Building, Chicago, in the State of Minnesota, with headquarters at 124 Davidson Block, St. Paul.

THE PURITAN ELECTRIC COMPANY has been formed in New York City to make apparatus for furnishing and using electric power. The directors are J. R. Burnet, F. P. Delafield, B. A. Gould, Jr., Carl Schurz and Cortland Betts. The capital stock is $100,000.

THE COLUMBIA STEAM BOILER.

SINCE the early days of heat tube steam boiler practice every conceivable effort has been made to so construct them that an assured circulation, economy of space, efficiency of heating surface and cheapness of construction and repairs



THE COLUMBIA STEAM BOILER.

shall be provided for. Especially is it desirable in this class of boiler that it can be cleaned.

All these desiderata have, it is claimed, been combined in the Columbia boiler, built by the Columbian Steam Boiler Works, of North Eighth street and Driggs avenue, Brooklyn, N. Y., and illustrated in the accompanying engraving. As seen, it is composed of a central vertical shell surrounded by layers of U-shaped tubes. At the water line level is placed an enlarged chamber to provide for a steady water level and a ready liberating surface. It has an outer casing to form firebox and combustion chamber and to compactly inclose the boiler and tubes, as well as the furnace at the bottom.

In the construction of the Columbia boiler, none of the parts are bolted together, no packed joints, no diaphragm plates and no forced circulation are employed. This flexible construction, therefore, allows full play to the various parts and provides against all unequal expansion. There is ample steam and water space and the water surface is far enough from the steam exit to insure against any picking up of the water of the steam after the water spout method. The large water surface avoids rapid fluctuations in water level and provides at the same time for the ready release of the steam generated.

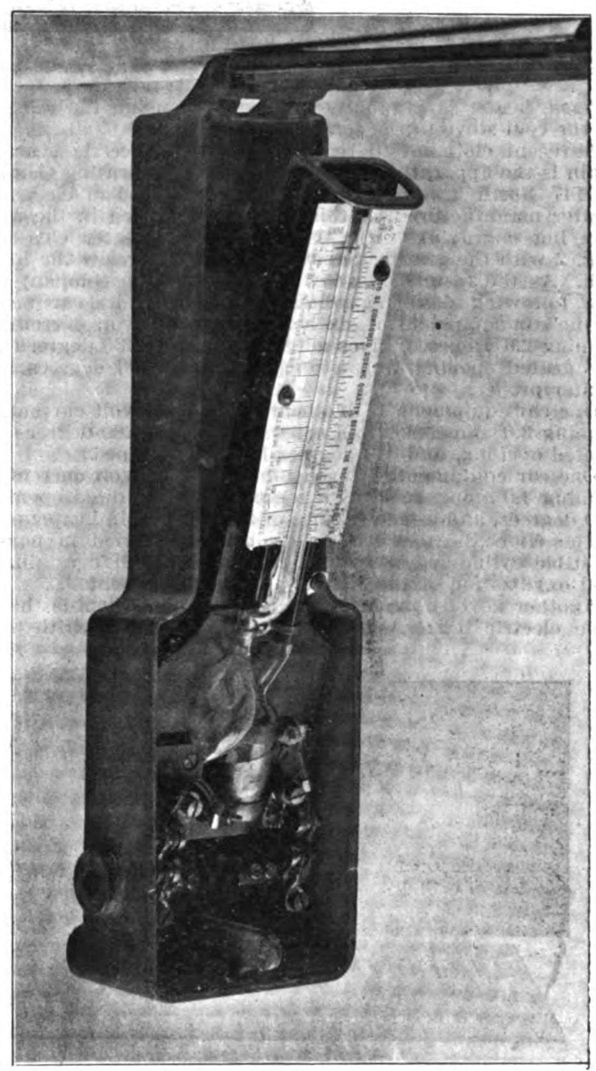
To assure cleanliness in the tubes and ready means for examination, they are shaped to large radius curves, with a quick rise to assist the circulation, and every possible provision is made to keep a supply of water within the tube portions most exposed to heat. Cleansing apparatus can be readily inserted and the boiler thus kept constantly at its maximum efficiency.

The question of safety has also been given every consideration, every part subjected to pressure or other stress being carefully proportioned to meet it.

The company will also shortly bring out a straight tube boiler.

THE WRIGHT DEMAND METER.

How to charge customers for current, and be just to all, and at the same time realize a profit on the investment, has always been a vexed question with station managers. The giving of discounts according to amount and character of the current consumed partly solves the difficulty, but only partly, since it leaves the station manager always in the dark as to the actual nature of the customer's consumption, especially



THE WRIGHT DEMAND METER.

as to the maximum current which he draws, and for which provision has got to be made at the station. The Wright Maximum Demand Meter has been designed to meet this difficulty, and its use abroad has been followed by the most gratifying results. Mr. R. S. Hale, of 31 Milk street, Boston, Mass., has acquired the American rights for this meter, and his article, appearing elsewhere in this issue, gives a good idea of its great usefulness. Mr. Hale will be glad to give any additional information regarding it.

The apparatus is extremely simple and is described in detail in the article by Mr. Hale, referred to above. The accompanying engraving shows the meter with the cover open and the scale swung forward and upward. As the entire apparatus

contains no moving parts, except the liquid in the tube, which is hermetically sealed, it is impossible for it to get out of order. Mr. Hale has already received trial orders from the Edison stations in New York, Boston, Chicago and elsewhere.

THE GLOBE ELECTRIC HEATERS.

With the approach of winter, electric railway companies are looking about for means to heat their cars properly. The most convenient method, of course, is the electric, and hence the electric heater is gradually but surely causing the relegating of the coal stove to the scrap heap.

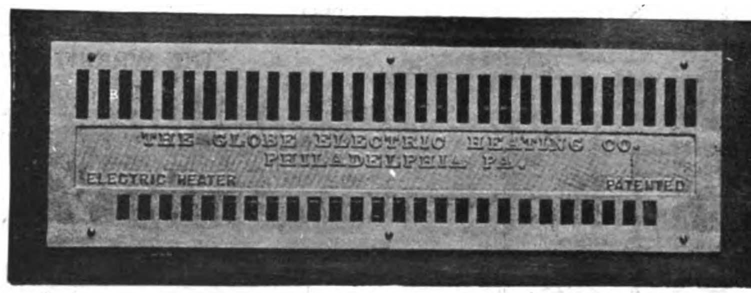


FIG. 1.—GLOBE ELECTRIC CAR HEATER.

A recent claimant to recognition in the electric heater domain is the apparatus of the Globe Electric Heating Company, of 147 North Twelfth street, Philadelphia. The electric car heater manufactured by this firm is illustrated in the accompanying engravings, Fig. 1 showing the heater closed and Fig. 2 with the grating removed, exposing to view the heating coil. As the results of a six months' test the company gives the following data regarding the work of its car heaters:

One car equipment of six heaters on a 500-volt current, consuming 2.6 amperes, gives a temperature of 180 degrees F. at the grated opening, and a temperature of 300 degrees in the heater proper.

One car equipment of five heaters on a 500-volt current, consuming 3.0 amperes, gives a temperature of 200 degrees F. at grated opening, and 340 degrees in heater proper.

One car equipment of ten heaters on a 500-volt current, consuming 4.0 amperes, gives a temperature at grated opening of 160 degrees, and a temperature of 290 degrees in heater proper.

The Globe heaters have their coils embedded in non-combustible cylinders, in such a manner that all crystallization and oxydization of the wire of the coil is prevented.

Another novelty manufactured by the same firm is the portable electric heater, illustrated in Fig. 3. This little heater contains six heating coils similar to that shown at A. They are screwed into place by means of an ordinary lamp socket. They can thus be removed and renewed like an ordinary incandescent lamp.

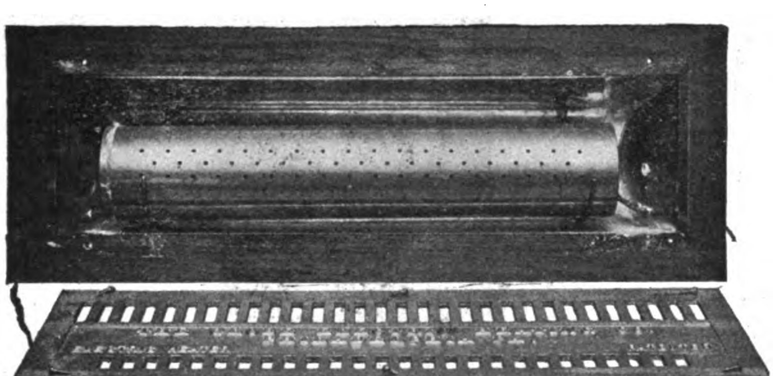

FIG. 2.—GLOBE ELECTRIC CAR HEATER.

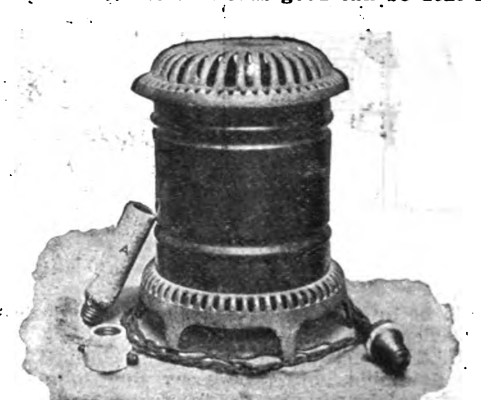

FIG. 3. GLOBE PORTABLE ELECTRIC HEATER.

This portable heater consumes 3.5 amperes at 110 volts, the temperature of the coils being 680 degrees F. The little heater is specially adapted for office use, heating of bathrooms, etc.

R. D. NUTTALL COMPANY have removed their Boston office from 180 Summer street to 31 State street. Mr. Chas. N. Wood, who has had charge of their New England business in electrical and railway supplies, will continue in charge at the new location, where they will be glad to receive inquiries and fill orders promptly.

WOOD PRESERVATION FOR ELECTRIC RAILWAYS.

A large portion of the construction of electric street railways consists in the pole line and in the track, which again depends largely on the quality and durability of its wooden sleepers and stringers. If the poles and sleepers can be preserved, the physical condition and the value of the property is to that degree enhanced. The subject is one that has long received the careful and serious attention of electric railway and electric lighting men, and a good means of preservation is universally recognized as a desideratum of the first importance. The thought of the American Street Railway Association has already been engaged with the matter, and the present is a fitting time to point again to the good results accomplished with Carbolineum Avenarius, sold by the Carbolineum Wood-Preserving Company, of which Mr. C. S. McKinney is manager, the New York office being at 21 Cliff street. The users of this material are legion, and among the best pleased are those in the electrical field, as the following little list will serve to exemplify: Western Union Telegraph Co., Southern Bell Telephone and Telegraph Co., American Bell Telephone Co., Ohio Valley Telephone Co., The Mason Telephone Co, Southwestern Telegraph-Telephone Co., Titusville (Fla.) Electric Light Co., Sumter (S. C.) Electric Light Co., Edison Electric Illuminating Co., N. O. La.; Consumers' Electric Light and St. R. R. Co., Tampa; Austin Rapid Transit Co., Austin Water, Light and Power Co., Memphis Light and Power Co., Laredo Electric and Railroad Co., Erie Telegraph and Telephone Co.

It is obvious that when the ties are well preserved, under such high grade asphalt and paving as many roads and cities now lay, the necessity of spoiling such pavement by ripping it up is reduced to a minimum. A great many testimonials could be cited in favor of this preservative, but the company will be glad to send data of all kinds upon application. It is surprising to note how much miscellaneous good can be done by the general use of the specific, so long as the genuine article is used, a point upon which the New York Central Railroad lays particular stress in its engineer's instructions to all its contractors and inspectors.

A FEW POINTERS ON SPECIALTIES.

The John Wennstrom Company, of Forty-first street, Brooklyn, report a good inquiry for their jewels for all classes of recording instruments, which they are now furnishing in large quantities to the makers of such electrical apparatus. They also supply rubies for phonographs, and, in fact, the jewel work in all apparatus of such character. They make also fine tools in these lines and furnish dies and drawplates, their

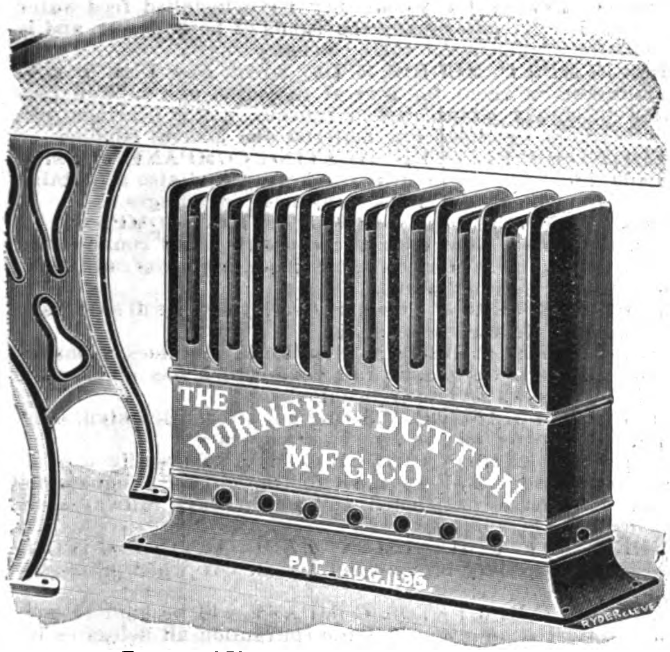
sapphire dies for filament drawing being well known. They will be glad to receive and respond to inquiries on all such matters.

In a kindred line is the work of Mr. D. S. Plumb, 24 Boudinot street, Newark, a large manufacturer of special clockwork for recording apparatus of all kinds, and of counters for gas, electric and water meters. Mr. Plumb supplies not only a large amount of the material thus used in the electrical trade but that used in the steam line, for recording gauges and other fine apparatus. He makes also special tools, and will be glad to furnish estimates on work from samples, or models and drawings. Concerns introducing new appliances of a delicate mechanism will do well to communicate with him.

THE DORNER & DUTTON ELECTRIC CAR HEATERS.

THE accompanying illustration represents one of the new types of heater now being introduced by the Dorner & Dutton Manufacturing Company, of Cleveland, O., and is worthy of special mention as it embodies a new principle in electric heater construction, doing away entirely with the use of wire. Each heater contains 12 feet of 1½ inch porcelain tubing, filled with carbon compound, which cannot be burned out. Four amperes passing through this compound will keep the outside of this tubing at a temperature of 310 degrees. This tubing is encased in neat open work frames, which allows a free circulation of air, thus insuring free radiation of heat.

The heat passing out through the openings of the frames does not heat the frames sufficiently to burn any kind of



DORNER & DUTTON ELECTRIC CAR HEATER.

cloth; hence, the frames can be put outside of seats without any danger of burning clothing, and thus getting greater benefit from the heaters than when put under the seats. The tubes having a much greater surface exposed than wire, give off a greater heat than wires, and cannot burn or rust out.

A set of these heaters consists of four heaters wired two in series, which are equal to 48 feet of 1½ inch steam pipe, except that the tubes of these heaters will, with four amperes on a 500 volt circuit, be 90 degrees hotter than the steam pipe will be with steam at 85 pounds pressure.

The company furnish two switches, so that only one-half, or two amperes of current may be used when that is sufficient.

The company manufacture two styles of heaters for street car service. That shown in the accompanying engraving, intended for cross-seats, is compact and can be placed in any convenient position and fastened to the floor. Another style for side seats, can be fastened to the sides or risers of seats and does not deface the finish of the car.

The heaters are waterproof, very simple in construction, thoroughly insulated and require no repairs. These heaters are also adapted for buildings, house or office use.

THE CENTRAL ELECTRIC COMPANY think that there is a decided improvement in feeling among the trade. Buying is freer and the general indication such as to warrant hopes for a reasonably good fall trade.

GALE'S COMMUTATOR COMPOUND.

K. McLennan & Co., of Chicago, sole manufacturers of the celebrated Gale's Commutator Compound, report their sales during the past year more than double that of any previous year. The satisfaction which the compound has given generally has exceeded their most sanguine expectations, and they are in receipt of enough testimonials unsolicited "to fill a volume." In response to numerous requests from their customers, the Fort Wayne Electric Corporation recently made a careful and exhaustive test, and the result, as expressed by them, is as follows: "The application of Gale's Commutator Compound was attended with very satisfactory results. A slight sparking occurs at the moment of applying the compound. This, however, disappears instantly, and the commutator assumes a hard gloss. We recommend it to those having trouble with sparking, cutting of commutators, etc." The test was made under the personal supervision of Mr. Barnes. Mr. M. J. Isaacs, of K. McLennan & Co., states that this is but one of hundreds of similar tests, and with similar resu'ts. He will be at the convention with sufficient samples, so that every delegate may make a test and convince himself of the merits of the compound. In the mean time samples may be had on application to their office, Marquette Building, Chicago.

TELEPHONE MANUFACTURE IN ST. LOUIS.

Among the hustling, enterprising different manufacturing companies of the city of St. Louis may be mentioned the Missouri Telephone Manufacturing Company, located at Nos. 917 and 919 Market street, in close proximity to the Auditorium, where the display of the electrical apparatus was made during the convention. They manufacture everything in telephones and switchboards. The latest acquisition to their line of telephones is an instrument designed for street railway work, the operation of which is as follows: A telephone is carried upon each street car. In case of accident or at any time should a conductor des're to communicate with headquarters, or any of the central offices he takes his telephone to the nearest pole and hangs it on the wires. This puts him in circuit. He proceeds to ring up the office, and after communicating lifts his telephone off the hook and takes it with him back to his car. By the aid of this instrument each car upon the road may at any and all times, within a few seconds, communicate to headquarters—a very valuable feature. They are placing a very low quotation upon this instrument, desiring to introduce them, believing that a large sale will more than pay for the trouble and pains expended in producing an instrument of this character. The entire instrument is no larger than an ordinary magneto bell. They will be pleased to show this instrument to the street railway men who visit St. Louis. They will also have samples of the same on display at the exposition and at their own display at the St. Louis annual exposition. All street railway men should call upon this company while visiting St. Louis, and they will be repaid by being presented with a very elegant calendar, beautifully got up, something entirely new, to hang upon their walls in their offices at home, which will help them to remember their visit to St. Lou's.

GOUBERT FEED WATER HEATERS IN STREET RAILWAY PLANTS.

The Goubert Manufacturing Company has enjoyed remarkable success in the introduction of its feed-water heater and its Stratton steam separator into electric railway plants. The capacity in some of the installations is enormous, showing that intelligence has governed in the selection of apparatus and in the plans to obtain high station economy. We give below a list of some of the roads now using Goubert heaters: St. Louis & Suburban Street R. R. Co, St. Louis, Mo., 2,400 h. p.; Metropolitan Street Railway Co., New York City, 10,800 h. p.; Third Avenue Cable Railway, New York City, 6,000 h. p.; Atlantic Avenue R. R. Co., Brooklyn, N. Y., 5,000 h. p.; Nassau Electric R. R. Co., 2,000 h. p.; Syracuse Street Railway Co., Syracuse, N. Y., 1,600 h. p.; Buffalo Railway Co., Buffalo, N. Y., 4,000 h. p.; Staten Island Electric R. R. Co., Staten Island, N. Y., 2,700 h. p.; West Side Street Railway Co., Elmira, N. Y., 400 h. p.; Newburgh Electric Railway, Newburgh, N. Y., 500 h. p.; Bergen County Traction Co., Fort Lee, N. J., 700 h. p.; Consolidated Traction Co., Jersey City, N. J., 1,500 h. p.; New Jersey Electric Railway Co., Secaucus, N. J., 1,000 h. p.; Fairhaven & Westville Electric Railway, New Haven, Conn., 1,220 h. p.; Waterbury Electric Railway, Waterbury, Conn., 1,500 h. p.; Metropolitan Railroad Co., Washington, D. C., 2,500 h. p.; Brooklyn Street Railway Co., Cleveland, O., 1,600 h. p.; Philade'phia Traction Co., Philadelphia, Pa., 12,000 h. p.; Electric Traction Co., Philadelphia, Pa., 1,200 h. p.; Portland Railroad Co., Portland, Me., 1,840 h. p.; Worcester Electric Railway, Worcester, Mass., 500 h. p.; Telegraph Avenue Electric R. R., Oakland, Cal., 390 h. p.; Halifax Electric Tramway

Co., Halifax, N. S., 1,200 h. p.; Montreal Street Railway Co., Montreal, P. Q., 2,000 h. p.

PHŒNIX CARBON BRUSHES.

The fact that the Phoenix Carbon Manufacturing Company, of St. Louis, has facilities for making 5,000 carbon brushes daily gives an idea of the extent to which the use of such brushes has become universal. In fact, no small part of the success of the trolley car is due to the introduction of the carbon brush and to the improvement of that article. The Phœnix Carbon Company was formed under the laws of the State of Missouri, and has a paid up capital of $160,000. It manufactures everything—electric light carbons, battery and telephone carbons, and all sorts of carbon specialties, such as brushes of all kinds and sizes.

Col. S. G. Booker, the superintendent, has been in the carbon business from the start, and has made it a special study in all of its details, being well known in the art and trade.

STEAM ENGINE GAUGES AND INDICATORS.

A visit to Schaeffer & Budenberg's busy factory, in Brooklyn, shows at once that despite the average dullness, the demand for their product and the quantity of their output have not declined. Quality is a great factor when it comes to holding trade, and this is a fact plainly visible in the reputation built up by this concern. Their gauges for all purposes are acknowledged to be the standard of the world. We understand they have sold upwards of 2,000,000, and the striking assertion is even made that they are at present turning out more than half of the whole product of all the manufacturers in Europe and America combined. Their tachometers, portable and stationary, used for the purpose of indicating the speed of dynamos and high-speed engines, are meeting with a brisk demand in the electrical trade. The Metropolitan and Columbia pressure gauges are of their make, and used everywhere for indicating steam, air, water, gas, ammonia and hydraulic pressures. Looking through their interesting and instructive catalogues one finds enumerated also such specialties as Thompson's steam engine indicator, Prof. R. C. Carpenter's throttling steam separating and coal calorimeters; test pumps, Acme steam traps, engine registers, dynamometers, injectors, test pumps for boilers and pipes, engine and boiler appliances in general. The large catalogue is divided into several sections, Part IV., for example, being devoted to steam engine indicators and Part I. to steam gauges. Any and all of their catalogues will be sent to any address on application by our readers. The general offices and works of Schaeffer & Budenberg are in Brooklyn; the New York salesrooms are at 66 John street, and the Chicago quarters at 22 West Lake street.

PLEASE PUSH IN THE CARS—DON'T SHOVE.

Every one who rides in a positively modern, up-to-date trolley car, cannot fail to be impressed with the number of improvements it embodies. Not the least of these, so far as the comfort of the passenger and convenience of the conductor is concerned, is the push button, handily placed at the back of each passenger, so that the signal to stop can be given to the conductor, without rushing, crowding or anxiety, under any circumstances. Huebel & Manger, of Brooklyn, N. Y., have furnished a great many of these car pushes during the past two years, for cars all over the continent. They are a great feature in the smooth operation of a trolley road.

EDISON-BROWN PLASTIC RAIL BONDS.

There is no detail of electric railway track construction of greater importance than the joint between the rails. This applies to the mechanical as well as to the electrical element, for the latter may cause not only a constant loss of power, but if defective may deflect the current into neighboring pipes and conduits, with results that are only too well known.

To what extremely low resistance such joints can be brought is shown in a table of tests of the Edison-Brown plastic rail bond just issued by Mr. Harold P. Brown, of 68 Broad street, New York, and printed in our advertising pages this week. These tests which were made with Weston instruments, show that the various types of plastic bonds with a current of 1,500 amperes passing through the joint cause a drop in potential varying 0.9 to .0064 volt, depending upon the weight of rail and type of bond employed. The best record was made with a joint consisting of a V-shaped slot cut in the web of the rail at the joint, with a steel cup holding the plastic alloy. With 100 amperes passing through the joint the drop was only .0004 volt, while with 1,500 amperes, as stated above, the drop was .0064, with the joint cold at the end of ten minutes. This is a remarkable showing and will not fail to impress itself on those directly interested.

POWER TRANSMISSION.

TRANSMISSION OF NIAGARA POWER TO BUFFALO.

BY ORRIN E. DUNLAP.

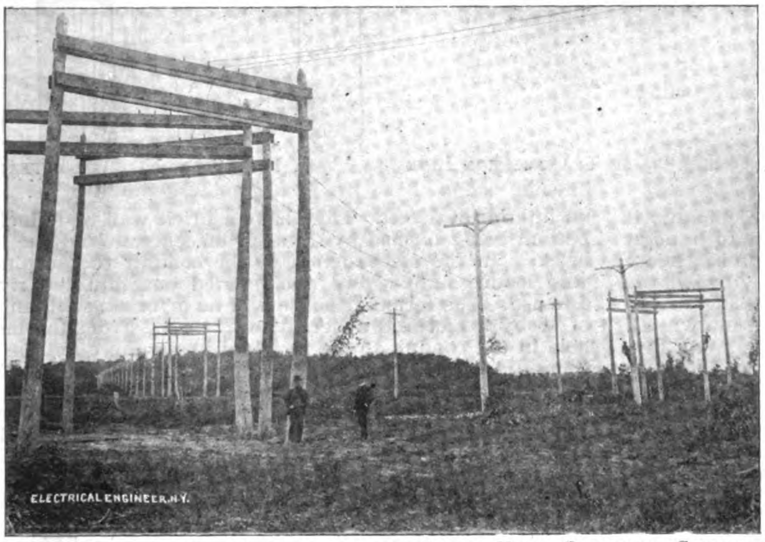
THE progress that has been made in the construction of the Niagara-Buffalo power transmission line is such that it cannot fail to be satisfying to even such an anxious people as the residents of Buffalo. The contract for the work is held by the White-Crosby Company, who have as their superintendent Mr. John A. Wilson, with his office in North Tonawanda. Under the efficient supervision of Mr. Wilson, the transmission line has been built with truly wonderful rapidity, and to-day it stands as another connecting link between the Queen City of the Lakes, Buffalo, and the Power City of the World, Niagara Falls.

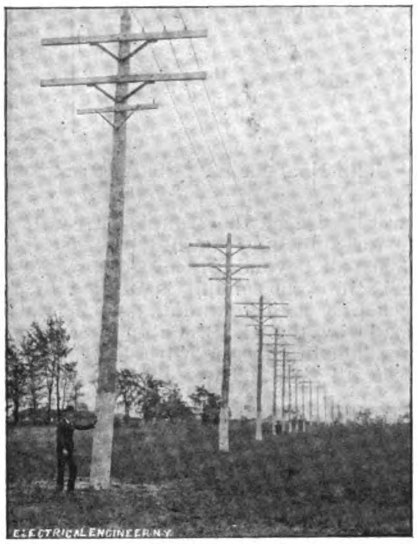
For nearly twenty-six miles this link of copper stretches in its brightness through city and village and across country, and as there are three conductors, or one three-phase system, the total length is nearly seventy-eight miles.

Starting from the transformer building on the east side of the Niagara Falls Power Company's central power station, the transmission line extends along the northerly side of Adams avenue on the power company's property to a point one and one-half miles east of Sugar street, where it leaves Adams avenue, and runs along the west side of and adjacent to the right of way of the Niagara Junction Railway. It then runs to a point about 500 feet north of the Mile Line road, where it turns at right angles and runs nearly due east through the power company's land and through private property to a point about one mile north of La Salle. From this point it runs along adjacent to the old mile line survey all the way to Tonawanda Creek, following, in general, the old line established as far back as 1798 and re-established for this purpose by surveys, old maps, notes and persons and by a new map filed in the county clerk's office in Lockport.

The line crosses the Tonawanda Creek at or near Division street, in the village of North Tonawanda, and then passes in a southerly direction across the right of way of the proposed Buffalo, Thousand Islands & Portland Railroad to Ellicott Creek, which it crosses, and continues in a southerly direction over private property to the south line of the village of Tonawanda. It follows this boundary line in a westerly direction for about a mile and a quarter, then crosses private property in a northwesterly direction to the east bank of the Erie Canal, which it strikes near the foot of Hinds street, in the village of Tonawanda, and for the remaining distance to Buffalo it extends along State property, the canal bank, on the east or heel path side. The pole line ends about 300 feet north of Brace street, in the city of Buffalo, at which point the conduit work commences, and for the last 4,200 feet the cables will be laid underground.

Throughout its length the transmission line runs for nearly eighteen miles through private property, a right of way 30 feet wide having been purchased by the Niagara Falls Power Company. Two and one-half or three miles of the line is built within the limits of the city of Buffalo, and about five miles of it along the bank of the Erie Canal, the right of way for which was obtained through the franchise granted by the State to the Cataract General Electric Company, this being the first construction going to show how widely beneficial the granting of this franchise is likely to be, not alone to the canal, should electricity be adopted as the motive power thereon, but to many villages and cities throughout the State. In its route the transmission line passes through the City of Niagara Falls, the town of Niagara, the town of Wheatfield, the village of North Tonawanda, the village of Tonawanda, and also through a small portion of the city of Buffalo. These places are located in Niagara and Erie counties, which naturally will receive the greatest benefit from the Niagara power development and transmission.





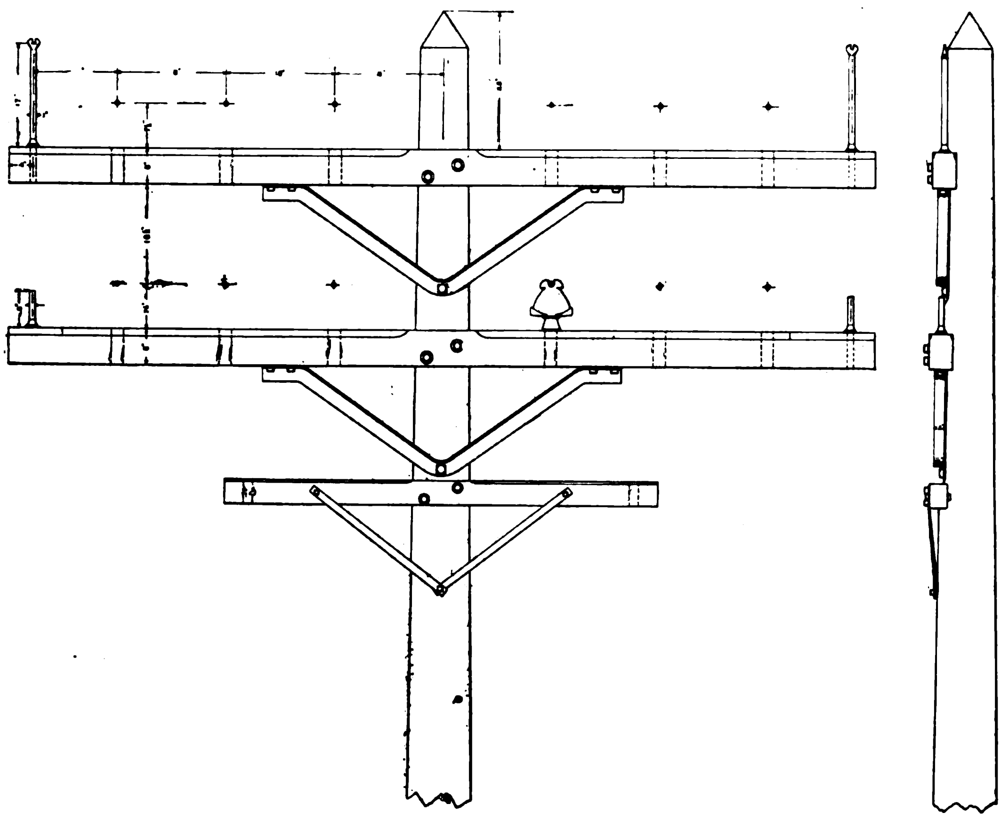
THE NIAGARA-BUFFALO POWER TRANSMISSION LINE.—VIEW SHOWING CONSTRUCTION AT POINTS OF TRANSPOSITION, CURVES, AND STRAIGHT RUN.

The construction of this transmission line has been a task of no small magnitude. Work was commenced on August 14, and nearly 200 men put to setting poles. In all, there were six gangs at work on the pole erection, two of which worked from the Falls toward Tonawanda, two from Tonawanda toward the Falls and two from Tonawanda toward Buffalo. In length the poles vary from 35 to 65 feet. They are of white cedar, shaved, and have all been placed in position. In order to facilitate the work, the poles were shipped to North Tonawanda, La Salle and Niagara Falls, and when the construction was along the canal a boat was used, the White-Crosby Company having a steam tug and a naphtha launch on the work to transport men to and from the scene of their labors. These

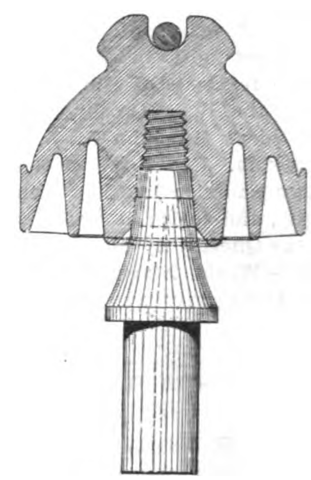
boats were kept at Tonawanda, the canal being used in the run toward Buffalo and the river for trips down stream.

One of the illustrations accompanying this article portrays the manner in which the conduit was constructed along the bank of the Erie Canal in Buffalo. Starting in the rear of the power house of the Buffalo Street Railway Company, it extends for a distance of nearly 4,200 feet north to a point about 300 feet beyond Brace street, where the terminal house will be built. The conduit is formed by twelve vitrified tile ducts, each 3 inches in diameter in the clear. These tiles were made by the H. B. Camp Company of Greentown, O. They are laid in concrete with 4 inches as the minimum protection on all sides. Three of the ducts will be sufficient to carry the cables first laid, but with their usual foresight the Niagara Falls Power Company are making provision in this construction for twelve cables. The depth of the conduit trench is about 40 inches, but this was governed somewhat by the conditions met with, the average depth of the soil covering over the conduit being about 18 inches. In no place does the conduit approach the edge of the canal bank nearer than 14 feet, its inside line holding close to the 16-foot mark.

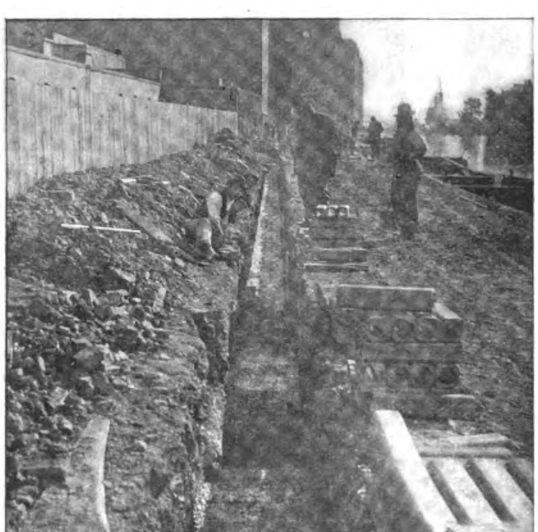
In all, there are about sixteen manholes along the line of the conduit, their location being governed mainly by the condition of the locality. These manholes are octagonal in form, with an interior of 5 feet. They have a brick wall of 12 inches, the bottom being formed by 6 inches of concrete and one layer of brick. In the construction of the conduit the surplus earth was loaded onto scows and carried out into the river and dumped. The terminal house will be of brick, with an interior of 16 by 9 feet and a height of 22 feet. From the last manhole in the conduit to the terminal house there will be a short tunnel about 4 feet long. The anchorages of the cables will be on the poles outside.



The Niagara Falls-Buffalo 20,000 H. P., Three-Phase Transmission Line.



Insulator, Niagara-Buffalo Line.



The Conduit Section along the Canal.

The cable to be laid in the conduit will be lead-covered and furnished by The Safety Insulated Wire and Cable Company, of New York, under strong insulation guarantees. This cable will have a conductor equal to 350,000 c. m., and aggregates 12,345 feet in length for the three circuits. The rubber insulation is 9/32 inch thick, covered with rubber tape. The lead sheath has a thickness of 7/64ths inch, and contains 3 per cent. of tin. Tests of the cable on the ground showed it to be capable of withstanding 40,000 volts without injury. This lead cable will be carried upon a trestle inside the terminal house, where the ends will be sealed, and a rubber insulated wire without lead will be carried out as far as the first pole, the distance probably being about 20 feet, and there it will be connected with the bare copper cable of the pole line. The terminal house will be equipped with lightning protectors.

The transformer house at the Buffalo end of the line will be 16 by 20 feet inside and located in the rear of the Buffalo Railway Company's station. It will be almost entirely below ground, and in it will be placed the static transformers, the rotaries to be located on the power house floor, it is understood. The electrical equipment of this line, it will be recalled, will be supplied by the General Electric Company.

The illustrations presented herewith give an excellent idea of the headway made and of the manner in which the pole line is constructed, but do not show it in its finished state. In securing the right of way over private property many difficulties were encountered, all of which were met and overcome by the remarkable determination and energy of the Niagara Falls Power Company, with the result that the route selected is quite direct in its general line. In some cases farmers were loath to divide their farms by selling a strip 30 feet wide at or near the center, and this forced the line to the bor-

ders of some of the farms, causing some circuitous places, as will be seen by the illustrations. Then, again, the route of the proposed Buffalo, Thousand Islands & Portland Railroad, as well as other railroads, had to be crossed.

The poles are set at a depth of 6½ to 8 feet, and where soft soil was met they were set in concrete. For the main, however, they are placed right in the ground and thoroughly well tamped, the soil being of very hard clay. In fact, it is stated, that the men found the work of excavating for the poles very hard, the clay being exceedingly firm. The poles are set to the east side of the center of the right of way, the outside line of the 30-foot strip being 1 foot beyond the end of the outside line of the large crossarms. The two top crossarms are 12 feet long by 4¾ by 5¾ inches, and made of yellow pine. Both of these crossarms are designed for power conductors. They are supported by braces made of 2 by 2-inch angle iron. The lower or telephone line crossarms are 6 feet long by 3¼ by 4¼ inches. They are supported by 1½ by ¼-inch iron braces. The crossarms are all staggered, the gains being painted before the arms are set. Where double crossarms are used at corners and other angles in the line, they are fastened by ¾ by 10-inch lags and ¾-bolt through all parts. All poles set at angles will be guyed by a ¾-wire strand and turnbuckles to the bottom of the opposite pole.

The line conductors consist of nineteen-strand cables, each of 350,000 c. m., and furnished by the American Electrical Works of Providence, R. I. These are shipped on reels weighing about 2,800 pounds, and containing about half a mile of cable. In connecting the ends the inner core is removed and a half connection made, which is soldered. In stringing the cables the reels are loaded on a cart having wheels of 5 feet 4 inches and a tread of 3 inches. In this way the cable is run out, and the simple movement of a lever brings it up taut on the poles. The poles are all to be painted with two coats of pure white lead and boiled linseed oil. They are set from 60 to 75 feet apart, but the distance is varied in order to overcome the vibrations of the spans. Complete transposition is effected every five miles, and at these five points on the line two poles which are 5 feet higher than the adjacent poles are placed. One of these transposition points is shown in the accompanying illustration, the first two poles showing above the margin of the woods to the left in the picture being a set of the poles referred to.

In turning corners six poles and double crossarms are used in order to distribute the strain of the cables on six instead of three pins. The pinholes have a depth of 4 inches, and all have drainage holes in them. The pins are boiled in linseed oil and their butts are painted. They are not nailed in position until after the double petticoated insulators are screwed on. The upper crossarms are prepared for pins on which galvanized iron barbed wire will be strung at a height of about 18 inches to afford protection from lightning. These wires will be grounded at frequent intervals.

The insulators will be of the triple-petticoat, helmet pattern shown in the engraving. The cable will rest in a groove at the top, and the rim of the helmet will lead the water to the ends, so that the drippings will fall clear of the crossarms. These insulators are designed to withstand a pressure of 40,000 volts.

The expectation is that Niagara power will be sent to Buffalo before the close of November, but it is evident that the power company will not have any great amount of power to send to that city before the wheel-pit extension is finished. Mr. William A. Brackenridge, M. Am. Soc. C. E., chief engineer of the Cataract Construction Company, is in charge of the construction of the transmission line on behalf of the power company, and under his direction the transformer house adjoining the power house is being fitted for the part it is to perform in raising the voltage of the current. The electrical engineers of the world are watching the work at Niagara, and with success of the transmission of power to Buffalo will come another great victory to add to the many that have been scored in this power plant and by the men who own it, and also by those who have it in charge.

THE EARTH A GREAT MAGNET.

In a lecture entitled as above, delivered at Liverpool, Dr. J. A. Fleming considered the question of the nature and origin of terrestrial magnetism and said that if the greater part of the earth's magnetism was due to the materials of which the earth was composed being permanently magnetized, then it was tolerably certain that this magnetic effect was wholly confined to a layer not much more than twelve miles thick. The lecturer concluded by emphasizing the enormous importance of the work which had been done in studying the behavior of the compass in iron ships, and the improvements effected in the compass, chiefly in this century due to Lord Kelvin.

THE ALTERNATING MOTOR FOR FARM WORK.

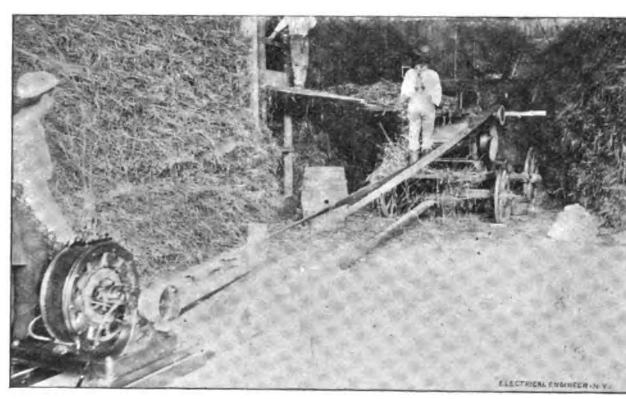
BY ROBERT E. DALLAS.

The Electric Barn.

ALTHOUGH a few attempts have been made at introducing the electric motor in driving farm machinery, these have been uniformly carried out by the aid of direct current motors. The writer has, therefore, deemed it of sufficient interest to describe what he believes to be the first instance of an installation of this nature operated by an alternating current motor.

We have been trying for some time to get hold of a good alternating motor that would start itself, especially on full load. A good practical motor of this description is exactly what we central station men need badly for the development of our business, and the opportunity to run day and night with a full load, which is the only paying load a central station can carry. A successful alternating motor would be of immense advantage to us and to the farming community around us, affording opportunity to furnish a safe and economical power within a radius of ten miles.

I think such a motor has been developed and perfected, with the exception of a few minor points, by Mr. J. J. Wood, of the Fort Wayne Electric Company. We have two of these motors in use here, a 2½ h. p., which is running a printing office on all kinds of work very successfully. The other is a 7½ h. p., installed on a farm about six miles away from our plant, and with which we have very successfully threshed this season's wheat, a crop of 450 bushels, and have also placed ten acres of corn in the farmer's silo. We threshed out the wheat in fifteen hours, a piece of work that it would have taken the ordinary traction engine used for this purpose three days, and



THRESHER DRIVEN BY WOOD ALTERNATING MOTOR, SIX MILES FROM STATION, KENNETT SQUARE, PA.

we filled the silo in ten hours, for which work the engine would have taken the same time as for the wheat, namely, three days.

The farmers seem very well pleased with the operation of the motor, and displayed great interest in watching it in operation, some of their comments being very amusing, indeed.

After being started the motor required absolutely no attention whatever, doing its work easily and noiselessly. Of course, the motor requires to be in step with the machine at the station, but we have no trouble from that cause, as it has only fallen out of step twice, and as all you need to do in that event is to throw over the switch and start it again, it becomes a very simple matter for the most inexperienced person to manage.

One objection to these motors is that they require a tremendous amperage at the start, but as the speed approaches nearer and nearer to synchronism the current decreases until the two are in step, when the current is about the same as the ordinary continuous current motor. Twice on starting this motor with load on, we blew 180 ampere fuses. They come up to speed very fast, however, and will come to synchronous speed in from five to ten seconds. They should, however, be fitted with transformer capacity to start on not less than 1,500 watts

to the horse-power. This 7½ h. p. in actual work with load on uses about 5,500 watts. For all general purposes where alternating current can be procured, I think the work this motor gives would fill the bill very well. Their cost, to begin with, is rather high, but this will decrease as the demand increases. They are easily moved and one motor could be used by several farmers where the current is available. They will surely bring a day business to many an idle central station.

Kennett Square, Pa.

TELEPHONY AND TELEGRAPHY.

THE NEW WESTERN UNION TELEGRAPH OFFICES IN BUFFALO

BY A. C. TERRY.

THE recent removal of the offices of the Western Union Telegraph Company in Buffalo from Brown's Building to the new Ellicott Square Building, has brought into existence one of the finest telegraph offices in the United States, and for convenience, comfort and sanitation, it is thought to be second to none.

The Ellicott Square Building is a model of completeness, and is reputed to be the largest office building in the world. It covers an entire block, and is 200 by 240 feet, and cost, with the land, $3,500,000.

The building is ten stories high, has a court or rotunda 70 feet by 110 feet, and there are over four miles of corridors. There are sixteen elevators, and its electric plant consists of four direct coupled Edison dynamos, three of 100 kilowatts and one of 75 kilowatts, or a total of 375 kilowatts.

In this building the new offices of the Western Union occupy 12,000 square feet of space, which is proportioned as follows: 1,900 square feet in the basement for the linemen's rooms, supply department, messengers' clothes-rooms, and cable room; 2,000 square feet on the first floor corner of Main and Swan streets for the receiving and delivery departments and the offices of the manager and his assistants, and 8,000 square feet on the tenth floor for the general operating room and bookkeeping department.

The wires of the Western Union Company enter the building underground through twenty iron pipes of a size suitable for cables of 100 wires. At present there are but 1,070 wires entering the cable room, in which there is provided a cable terminal board which is made up of six slate boards set 3 feet 6 inches from the floor in an iron frame. Three of the slate boards are placed on one side of the iron frame and the remaining three directly opposite. Each board contains 340 binding posts set in seventeen vertical rows, with twenty binding posts in a row. The underground cable heads are connected to the binding posts by twenty-wire cables, each cable completing one row.

From the opposite boards 100-wire cables are led directly to the main switchboard in the operating room, and all necessary cross-connections and changes in the main lines or loops are made in the cable room instead of at the switchboard.

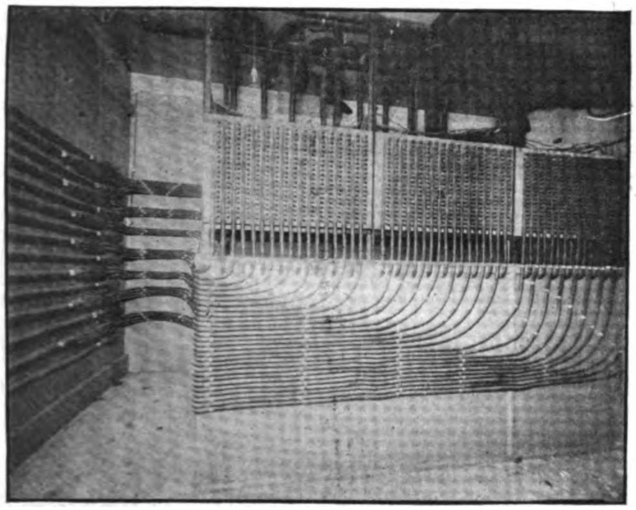
The cables reach the operating room through a shaft 3 feet by 4 feet and 115 feet long, expressly built for the Western Union.

In this shaft are placed fifteen iron pipes, 3 inches inside diameter, through which are pulled the 100-wire cables. The object of the iron pipes is to secure safety from fire. All the main lines and overhead loops are connected to the switchboard through W. B. G. fuses mounted on porcelain blocks. The switchboard is built in six sections of fifty wires each, and the whole is set in a steel frame with plate glass panels. There are 6,000 pounds of steel in the frame. Lamps are used for resistances in the battery leads, and there are 620 of these resistance lamps over the switchboard, or 104 lamps directly over each section.

The operating room is 60 by 105 feet, and the ceiling is 18 feet high. The room is splendidly lighted by twenty-four windows in the side walls and a skylight 35 feet wide and 55 feet

MAIN OPERATING ROOM, NEW WESTERN UNION TELEGRAPH OFFICE, BUFFALO, N. Y.

long, containing thirty-six large sashes of translucent glass which can readily be adjusted for ventilation. Above the translucent glass is the roof of the skylight and the distance from the floor to the top of the skylight is 32 feet. The per-



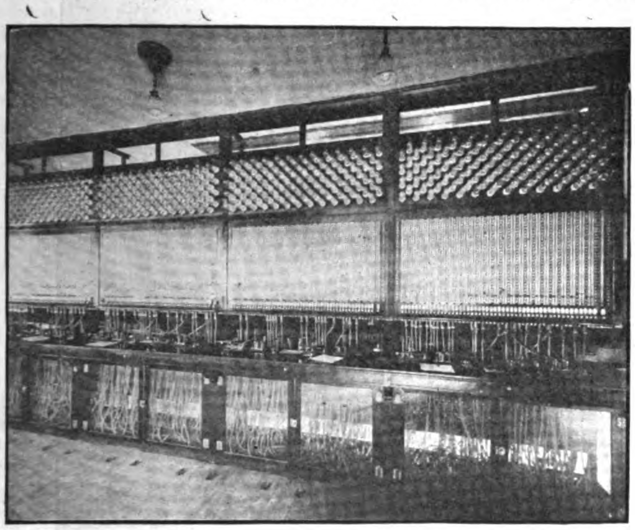
THE CABLE ROOM.

fection of the ventilating arrangements makes it an ideal room from a sanitary point of view.

At night the room is lighted by 150 incandescent lamps.

Ten feet from the switchboard and extending across the room, are four tables 25 feet long and divided into ten sections each. These are for the automatic repeaters. All the other tables in the room are octette, and there are twenty-one of them, with space for six more as facilities demand. All the tables are arranged to accommodate typewriters.

On these tables are distributed 112 single Morse sets, sixty-two sets of duplexes and thirty quadruplex sets, which are connected to the switchboard by four and eight-wire cables laid in 5 x 10-inch wire ways built in the floor, which is constructed of concrete cement and slate. In order to provide



THE MAIN SWITCHBOARD.

for the wire ways the Western Union raised the floor 5 inches above the ordinary level at a cost of $5,000. The wire ways run lengthwise and crosswise of the room, and are covered with slate slabs 12 inches wide and from 2 to 4 feet long.

In the western end of the room is erected a gallery 8 feet wide, 40 feet long and 8 feet from the floor, which is used for distributing and stamping messages. The distributing of messages is accomplished by means of the Martin carrier system, which consists of three lines of elevated tracks, running from the gallery lengthwise through the room and each track has three stations and three carriers. The carriers are connected to an endless rope cable and the whole is operated by two 2 h. p. Crocker-Wheeler motors.

The current to supply the office is generated by sixteen Crocker-Wheeler motor dynamos, ten of which are kept constantly running and giving the following voltages: 6, 20, 80, 160, 240 and 350. The 6-volt and 20-volt machines are for locals and the remaining eight are both positive and negative. It is an interesting fact that before the installation of these motor generators, it was necessary to maintain 17,000 cells of gravity battery, requiring 52,000 square feet of shelving, at an annual expense of over $16,000.

The power current to run the rotary transformers is received from the Ellicott Square dynamo plant. There is also installed a Fort Wayne alternating current rotary transformer, which is operated by current received from one of the Buffalo General Electric Company's 1,000-volt circuits.

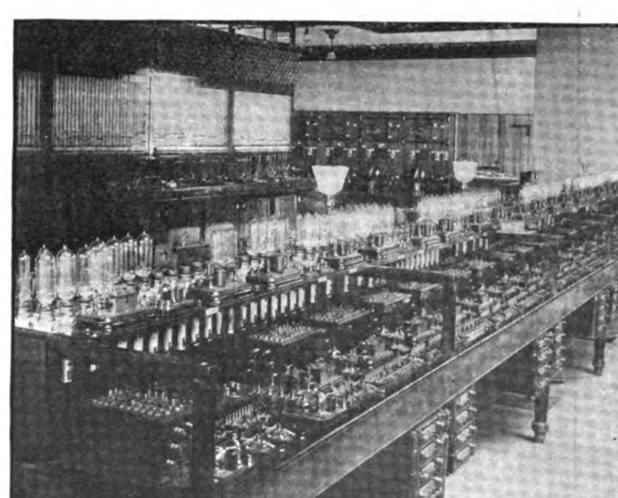
A static converter in the basement transforms the 1,000 volts to 110 alternating and the rotary transformer on the tenth floor transforms to 110 volts direct current. These two sources of current are connected to the motor dynamo bus wires by a

THE MOTOR DYNAMO ROOM.

double-throw switch. In one of the motor generator bus wires is connected one of Cutter I. T. E. single pole underload and and in the other bus wire is a Weston ammeter.
overload circuit breakers, of a capacity of 45 to 125 amperes,

Near the main switchboard is the loop or jack switch having 200 spring jacks. All the multiple sets and single repeaters are connected to this switch, so that it is possible to make up repeaters of any two multiple sets in the office, or from any multiple set to any single repeater.

The repeater system of the Buffalo office is the most extensive of any on the continent, and during the storm of September 30, along the Atlantic coast, no less than thirty-five multiplex circuits were repeated at Buffalo; and this, not including



THE AUTOMATIC REPEATERS.

three Wheatstone automatic circuits between New York and Chicago on which on the first day of the storm 10,000 messages were transmitted in ten hours.

The local business of the office is transferred from the oper-

ating room to the receiving and delivery departments by means of pneumatic tubes and a drop tube. The pneumatic tubes are 150 feet long and are operated by a steam jet. The message pouches or boxes require eight to ten seconds in transit.

The drop tube to the delivery department, which is 6 inches in diameter, has just sufficient exhaust by means of the steam jet to keep up a downward current of air. No message boxes or pouches are used in this tube.

The planning of the office was left entirely in the hands of the Buffalo management, subject to the approval of General Eckert, president of the Western Union, and Mr. A. S. Brown, electrical engineer to the Western Union, and the equipment of the office was in charge of Frank Kitton, chief operator, and A. C. Terry, assistant chief operator.

ELECTRIC TRANSPORTATION.

STORAGE BATTERIES IN USE BY THE UNION TRACTION CO., PHILADELPHIA.

THE most recent and most important step thus far taken in the United States in the application of the storage battery to electric railway work is embodied in the installation just completed by the Electric Storage Battery Company for the Union Traction Company of Philadelphia.

The plant under consideration is situated at the end of a feeder, eleven miles long. This year it was decided to extend the line several miles, and it was found that it would be necessary either to build a new power house or install a battery substation, as the required addition to the existing feeder system would necessitate such an enormous outlay for copper as to render it commercially impossible. It was found that the cost of copper alone, to carry out this extension and double the service on the section, would be four or five times the total cost of a battery installation to fully meet all the requirements; and that a new power house was out of the question on account of the heavy operating expenses.

Before the extension was made the pressure at the end of **the feeder was barely enough to operate cars on schedule time, and the pressure varied as much as 50 per cent. The recording voltmeter chart, Fig. 1, illustrates the effect of the battery**

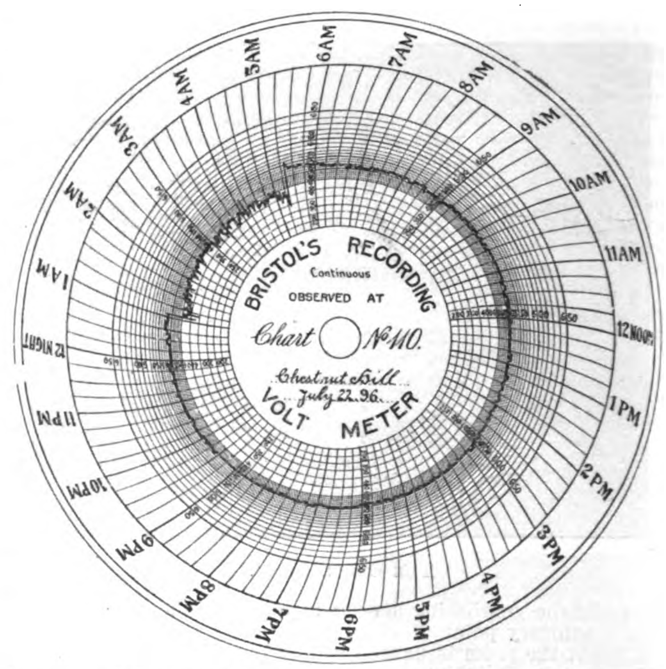


FIG. 1.—CHART SHOWING POTENTIAL ON RAILWAY FEEDER CONNECTED TO STORAGE BATTERIES.

as a regulator of pressure. During the four hours between 1 a. m. and 5 a. m., the only time when the battery is taken off the system, the fluctuation in pressure is very marked.

The current curve taken on the line shows that the battery

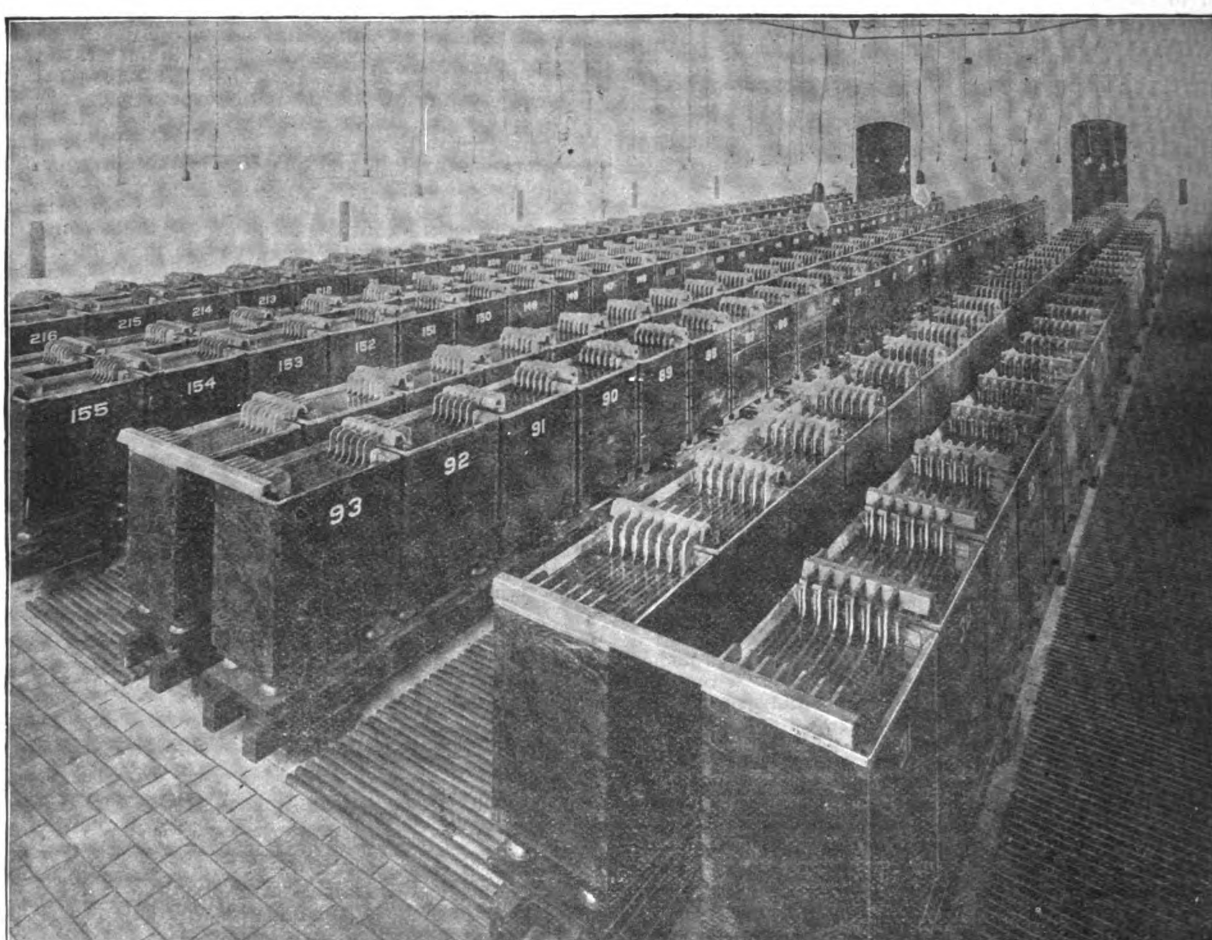

FIG. 2.—VIEW IN STORAGE BATTERY ROOM, UNION TRACTION CO., PHILADELPHIA, PA.

regulates to the extent of 200 horse-power; but it can be worked up to 800 horse-power in cases of necessity. The load on the section varies from 100 to 700 amperes; the feeder carries a constant load of 400 amperes, the battery discharging or charging to the extent necessary to maintain this condition. The result in actual practice is found to be that the feeder load remains constant at this average current and is absolutely independent of the fluctuating demand on the line.

Fig. 2 shows the battery house in which 248 cells are installed. Each cell contains thirteen plates, type "G," of the Electric Storage Battery Company's Chloride accumulator. The maximum discharge rate of the battery is 400 h. p. for one hour. The plates are contained in lead-lined boxes, mounted on two tiers of oil insulators. The connections are made by continuous weld, no mechanical contacts being used throughout the battery.

The Electric Storage Battery Company are at the present time installing several battery plants in street railway power houses. The battery in these cases enables the generators always to run at full load, and, consequently, at the highest point of efficiency, and to act as a cushion to the engine in the event of the circuit breaker opening when trouble occurs on the line.

PRESIDENT LITTELL ON THE STREET RAILWAY SITUATION.[1]

AMONG the most serious difficulties with which we have to contend to-day is the growing disposition of the government, whether State or municipal, to increase our burden of taxation. This disposition has increased of late years, and even within the last year, to a marked degree. The extraordinary prejudice against corporations, among people otherwise intelligent, causes them to be regarded as legitimate objects of attack and spoliation. Those who have once become affected with this prejudice seem to be unable to understand that a corporation is simply a collection of persons, by means of which individual resources, which would otherwise be frittered away in individual enterprises, are brought under one direction, making possible the success of large undertakings requiring an aggregation of capital. Of all corporations those which suffer most from this prejudice are those which exercise a public franchise, and the street railway franchise seems in particular to be a favorite object of restrictive legislation. With the arbitrary limitation of the rates of fare and the obligation of conforming the roadbed to every change in the street through which it passes, on the one hand, and the imposition of direct burdens of taxation in the way of personal taxes, taxes on roadbed, license taxes, franchise taxes, taxes on gross earnings and taxes on dividends, on the other hand, the financial limits within which the workings of a railroad are confined have become exceedingly narrow. Sometimes it almost seems as if the legislative agencies in our various States would not stop until they had brought the burden of taxation to a point where roads could no longer run.

For such a state of things it seems to me that the only remedy is to be found in that gradual enlightenment of the public, by which it will be induced to keep the imposition of financial burdens within reasonable bounds, and such a broad-minded and conciliatory management of the roads as shall in time do away with the last vestige of popular prejudice. Any successful business corporation manages and controls forces far greater than those which are at the command of a single individual, and its very power makes it an object of jealousy and attack. But I for one do not believe that the intelligence of the American people will in the long run go astray on this question any more than on any other. I believe that it is beginning to recognize, and will recognize still more clearly as time goes on, the necessity for combination and co-operation in all departments of business; and that if a proper spirit of moderation is shown—and this I consider of the first importance—by those in whose hands this extraordinary power is placed, the community at large will discover that the benefits which it derives from transportation corporations far exceed any subject of complaint which it may have against them, and will meet them upon the footing of a common interest without regard to the corporate character of the agency by which the power is exercised.

Another, and one of the severest strains to which street railway corporations are subjected, consists in the penalties imposed by courts, for the negligence of their employés. Recent years, and especially the last two years, have seen a great increase in the number of negligence suits and in the size of verdicts. There is a marked tendency at the present time, on the part of juries, to fix a higher scale in estimating damages for personal injuries. Cases where formerly verdicts of $2,500 were rendered, now often result in a judgment for $5,000, and others in like proportion. The State of New York has recently removed the limit of $5,000 in cases of death, so that now a verdict of $20,000 in a death case is by no means unusual. The doctrine of contributory negligence, which in theory and as duly expounded by the courts, in charges to juries, would preclude any recovery in cases where it is shown, seems only to be considered by juries—if considered at all—as a slight makeweight against the plaintiff in determining the amount of damages. Probably no class of cases exist in which it is so difficult to meet false testimony as in these, even when its falsity is perfectly apparent.

I do not mean to suggest for a moment that street railway companies are without fault in the matter of accidental injuries, but I do say that, profoundly as we must sympathize with the suffering and the unfortunate, we ought not to be compelled to pay the penalties of negligence where the negligence was due to the sufferer himself, nor should a case be sent to a jury where this fact is disclosed by the plaintiff's own statement. As well said some time ago by the General Term of the Superior Court of New York: "To leave it to a jury to say that such acts under such circumstances do not constitute negligence, would be to throw away the best understood legal standing, and substitute in its place any whim which might chance to flit through the minds or run in the emotions of uninstructed and unbridled jurors."

Whatever may be the ultimate result of existing tendencies in courts and juries, we may still hope for improvement in the matter of accidents, as people become more accustomed to the high rate of speed in their streets, which they now exact from street railways. No community which has had the benefit of rapid street transportation would ever be willing to go back to the old 5 or 6-mile-an-hour rate of horse cars. It must learn and it will learn it cannot have this benefit without a certain element of danger, and whether it runs the risk of this danger in traveling as passengers on the cars or in walking or driving in the roadway, it will come in time to take those precautions by which the great majority of accidents could readily be avoided.

For those accidents which no ordinary precaution on the part of the sufferer could avert, I believe there is one remedy and only one, and that lies in the hands of the management of street railways. That remedy is to be found in the discipline of the force. If discipline is slack, accidents will be frequent. If discipline is high and well maintained, accidents will be reduced to a minimum. As in every other great organization, the spirit which controls at the top penetrates through all the branches of the system, and the means by which it penetrates is the discipline maintained over the force by its head. In this one element of discipline I believe lies the secret of preventing the ruinous losses which follow from damage suits.

The last two years have seen the introduction of an unlooked for competitor in street, and especially in suburban transportation, and that is the bicycle. In some places where its use is peculiarly advantageous, it has undoubtedly cut down earnings very heavily. I do not believe, however, that in the long run the street railway business is going to suffer on that account. Anything to my mind that promotes in our American people the habit of locomotion, particularly of rapid locomotion, is beneficial to street railways. No doubt the bicycle has come to stay, and no doubt upon some suburban routes its competition has been serious, but it is still to a great extent a novelty, and when the effects of novelty have worn off, and the use of the bicycle is limited to those who will habitually make use of it all their lives, I think there will still be found quite enough people who prefer street cars as a means of locomotion, even in places where the bicycle can be used.

In spite of the disadvantages of which I have spoken, under which street railways suffer, and in spite of the financial difficulties which have prevailed for the last three years, and which have told as heavily upon street railways as upon any other interest, I believe they have before them a bright and prosperous future. In their prosperity every man, woman and child in our city communities, and in many rural districts, is directly interested. They have been of enormous benefit in spreading out populations over a larger area, in relieving densely populated districts in cities, and in making possible suburban homes, where the man who pursues his business in the heart of the city can live with his family at a distance from his office, and with them enjoy the benefits of space, of sunlight, of fresh air, of trees and gardens and of rural surroundings. This is especially true of the more modern forms of rapid transportation by which the time of transit is reduced. The luxury of such a home as I have described, to those of moderate means, who hitherto have been crowded into small and unwholesome flats or tenements, is one of the many blessings which the modern street railway has bestowed upon the

[1] Abstract of Adress Delivered at St. Louis Oct. 20, 1896.

community, and those who have reaped the benefits of it are not likely to forget it.

In conclusion, I desire to congratulate the association upon the large number of its members who are present here to-day, and to express the hope, in which I am sure all of you will join me, that this meeting will be the most harmonious, as well as the most interesting, that we have ever held.

THE MODERN POWER HOUSE.[1]—I.

BY RICHARD MCCULLOCH, COMMITTEE.

IN beginning a paper of this kind, it is usually considered proper to start with a sort of historical review, but in this case we are immediately struck with the fact that, unlike most modern institutions, the eventful history of the street railway power house has been condensed into the last few years. The conditions, the general design and the greater part of the machinery itself, have been evolved during the last ten years. All of these have changed rapidly and the manager who now deplores as antiquated a power house built six years ago, with the best existing machinery and in the light of the most approved practice, can say with Cicero, that it was not his fault, but the fault of the times.

It may be readily seen that there are two standpoints from which the design of the power house may be viewed. That of the one, who strives that the general plan, that each machine and that every arrangement shall tend solely toward the cheapest possible production of power; and that of the other who, while appreciating the position of the former, desires also that nothing shall enter into the design which will materially affect either the simplicity or the reliability of the plant. The cost of power on a large road is about 10 per cent of the total operating expenses, and it is almost a self-evident fact that the use of any apparatus which might produce unreliable service and thus impair the receipts and ruin the prestige of the road in order to save a small percentage of this cost of power would be very bad business policy. The first criterion of any machine installed in a power house should be absolute reliability, and the second, economy.

LOCATION.

A great deal has lately been written concerning the proper location of power houses and formulæ and graphical methods for determining this point have been derived, but we doubt very much whether any street railway power house has ever been located either by graphics or by the differential calculus. Unfortunately it usually happens, especially in cities, that the electrical center of the distribution system falls in very valuable ground entirely unsuited for a power house location and the final location is very often influenced by the extremely unscientific fact that the railroad company owns that particular piece of ground and cannot find a purchaser for it. In selecting a location, it is very important that a large power house should be placed on a railroad track so that coal may be readily and cheaply delivered, and it is very desirable that the location should be on some water supply in order that condensing engines may be used, unless the conditions will warrant the use of self-cooling condensers. If a location fulfilling these conditions can be found somewhere near the electrical center of distribution it is an ideal spot for a power house, but if in order to secure coal and water it must be moved from this point it should if possible be moved in the direction of future extensions of the street railroads. There are cases where power houses cannot be located on the steam railroad tracks, but the only excuse for such a location is where the interest on the cost of copper feeders running from the steam railroad tracks to the center of distribution would greatly exceed the cost of hauling of coal in wagons.

BUILDING.

The main points which should be borne in mind in the design of the building are that it should be light, airy, compact and fireproof. The shape and size of the building will be largely governed by local conditions, but there is one general arrangement which has been adopted in a number of the most recent power houses. This will be discussed later. There is no reason why anything combustible should enter into the construction of a power house. The walls may be of brick, the roof of slate, tile or iron, and the floors of concrete or iron. This method of construction not only increases security against fire, but it obviates the necessity of carrying insurance, the saving of which will in a few years pay the extra first cost. The building should be substantially constructed, but unless the location is on an important street there is no necessity of going to great expense to render the building ornamental, especially as all money which can be spared for this purpose may be far better invested in machinery to put inside the building. In erecting a building for use as a power house it is advisable to decide first on the style, size and arrangement of the machinery, so that no part of the building will interfere with the proper repairs, renewals and inspection of the apparatus. This may seem unnecessary advice, but it is a very common oversight for railroad companies first to decide on the style of building they wish, then let the contract for the erection of the power building, and then find themselves hampered in the use of some particularly desirable form of apparatus by the shape or contracted area of their buildings.

As by far the greater number of the modern railway power stations are operated by steam power, steam alone will be considered in this article. For convenience in discussion the apparatus in a power station may be divided in three classes: (1) The steam generating part consisting of the boilers, pipes and all their accessories, such as coal and ash conveyors, mechanical stokers, stacks, economizers, feed-water heaters, pumps, etc.; (2) the steam consuming part consisting of the engines, steam separators, oiling devices, condensers, etc.; (3) the electric part consisting of the dynamo, cables, switchboard, electrical instruments, etc. The division betwen the first and second parts is more easy and more marked, as it is usually accentuated in the power house itself by means of a brick wall.

STEAM GENERATING APPARATUS.

Beginning with what we have called the first part, we start with the choice of fuel. This is largely a matter of location. In a general way the proper fuel to use is that which will evaporate the greatest quantity of water per dollar's worth of fuel. It does not pay to burn too poor a quality of fuel, however, because slack containing a great quantity of ash and sulphur will cake and clinker on the grate bars, make a great deal of work for the firemen, refuse to be forced when necessary and make much ash to be removed. On the other hand, it will not do to make all arrangements for using a very expensive fuel, as a very little wasted in times when the furnaces must be rushed will make a great difference in the cost of operation. As an expensive fuel usually means one which is brought from a great distance, any furnace prepared for burning this would operate under unfavorable conditions if the supply is cut short by strikes or railroad blockades. Where the conditions are favorable for the use of oil, it makes an ideal fuel, requiring no handling, making no smoke or ashes, and allowing the fire to be regulated with the utmost nicety. Buckwheat anthracite coal is used largely by power houses in the Eastern cities. It is of high calorific value, clean, making no smoke and little ash, and capable of being readily handled in coal conveyors and mechanical stokers. In the western cities soft, bituminous coal is used by force of necessity. This brings with it the troubles of ash, clinker and dirt, and in the city renders necessary some form of smoke consumer. As has been stated, it usually happens that the choice of fuel is a matter of location, but in cities where several competing grades of coal come to market, it would probably pay to have expert tests made to determine what grade of coal or what mixture is most economical for the work.

It is hardly within the limited scope of this article to discuss the numerous forms of coal and ash conveyors which have been put in use. Several large companies make a specialty of this form of machinery and special designs are developed for each power house. We may say in a general way, that in power houses handling large quantities of coal, where the coal is all delivered at the same place, as by rail or boat, the installation of coal and ash handling machinery will pay. Where coal is delivered in small quantities and where it is delivered in wagons and may be dumped at any part of the boiler room, the reverse may be said. The advantage of this form of apparatus is its saving in labor, and its disadvantages are its great first cost, its expensive maintenance and the fact that it is desirable for the best service that the coal should be fairly uniform in size, which is a requirement not always easily fulfilled.

In the East the use of mechanical stokers has grown to such an extent that no large power house is considered complete without them. In most of the Western cities, however, and especially here in St. Louis, the mechanical stoker has not been a success. This difference in results may be attributed to the difference in the fuels used. The buckwheat coal of Brooklyn and Philadelphia feeds evenly on the stoker and causes no trouble by cementing the grate bars together by clinkers. With the soft, fragile, bituminous coal, however, clinkers soon form on the grate bars, and very often the fire must be almost completely destroyed to remove them. No mechanical stoker will bear crowding to any great extent and any power house using them must be supplied with a greater capacity of boilers than

[1] Paper read before the Amer. St. R'way Assoc., St. Louis, Oct. 19-23.

one where hand firing is the practice. By reason of the fact that the coal is introduced gradually into the hotter part of the fire and the volatile matter slowly driven off, a mechanical stoker is a partial smoke consumer. With the exception of this, there is no advantage in the use of mechanical stokers, except the labor saved, as the great efficiency which was formerly claimed for them has never been proved in actual practice.

Notwithstanding the great number of types of boilers on the market, they may be divided into two general classes—fire tube and water tube. In most of the more recent power houses, some form of water tube boiler has been adopted, as this type possesses some marked advantages over the fire tube. They are non-explosive, they can be operated at a higher pressure and consequently are more suitable for use with compound engines, they have a large heating surface and are quick to respond to calls for power, they occupy less floor space and are usually more intelligently designed than the other class. On the other hand, their first cost is greater, there is a greater number of joints to be looked after and the cleaning is more difficult, especially in those forms which use a curved tube. It has usually been considered that the efficiency of water tube boilers was much higher than the fire tube, but there is now a form of fire tube boiler being made consisting of a shell of large diameter and extra length, containing a large number of flues, which approaches the water tube very closely in efficiency. The high efficiencies obtained in boiler tests are seldom reached in actual practice as they usually result not so much from excellence of design in the boiler itself as from careful and intelligent firing during the test.

It is hardly necessary in presenting a paper before this intelligent body to discuss the reasons why water should be fed into the boilers as hot as possible. Besides preventing the straining of the boiler shell from the sudden changes in temperature, there is a large quantity of fuel saved, and the percentage of this saving will be found tabulated in nearly every work on thermodynamics. The usual methods employed in heating the feed-water are, first, by the heat of the exhaust steam, and, second, by the heat of the escaping flue gases. There are numerous patented devices for utilizing the heat of exhaust steam either by passing the exhaust through a number of pipes surrounded by the feed-water, or by spraying the feed-water across an opening through which the exhaust steam is admitted. Most of these devices are very simple in their construction and their efficiency depends very largely on the length of time the feed-water and the exhaust steam are in contact, and in case they are in separate chambers upon the conductivity of the separating medium. Care should be taken that the opening for the exhaust steam is never contracted, so that any possible back pressure on the engine is avoided.

The method of heating feed-water by the heat of the escaping flue gases has been applied in apparatus under the general name of economizers. The arrangement usually employed is a coil of pipe containing the feed-water placed in the flue. In order to keep the soot from settling on the pipes, most forms of economizers are supplied with a mechanism for scraping off the pipes whenever necessary. Sometimes the economizer consists of one large bank of pipes placed in the main flue, and sometimes the apparatus is divided into a number of banks placed in a flue leading to one furnace. The choice of arrangements depends largely upon the size of the plant and the general location of the boilers. By means of a properly designed economizer, feed-water may be heated to a very high temperature, even above the atmospheric boiling point of water. In the use of any device in which feed-water is heated by the flue gases, care should be taken that the escaping gases will still retain sufficient heat for the maintenance of the necessary draft after part of their heat is taken from them by the feed-water. In the case of power houses using natural draft, economizers should not be used, where the draft is not already sufficiently strong, or is just barely strong enough for the work to be done. There are in operation, however, many plants using natural draft, discharging flue gases at a very high temperature, much higher than is necessary to maintain the required draft. Economizers used in such cases would result in a marked gain in economy.

Whatever system of heating feedwater is used, the apparatus should be made abundantly large for the work to be done; first, that the water should pass through slowly and receive the full benefit of its contact with the heated gas or steam; second, that a large store of water may be kept on hand which is of great service in case of a sudden demand on the boilers, and, third, that the feed-water heating apparatus may act as a water purifier. It has been found that water kept for some time at a high temperature will deposit a great portion of the carbonates and sulphates of lime and magnesia which it has in solution. This is probably due to the expulsion by the heat of the carbonic acid gas contained in the water, thus freeing from solution the lime and magnesia which it is well known are slightly soluble in water containing carbonic acid gas.

With condensing plants the waste from the condensers is never at a greater temperature than 100 degrees F. and if hot feed-water is desired the use of an economizer becomes almost a matter of necessity, as the water from the pumps and the other non-condensing machinery would not have sufficient effect in heating the feed-water of a large plant.

Several of the large power houses built during the last few years have abandoned the use of stacks for producing draught, and are operating by means of an induced draft produced by fans placed in the flue or short stack. In this case the stack is just high enough to clear the roof. This system has many advantages. First, there are no stacks to blow down or fall down, and this point is of special importance in a region subject to tornadoes. The second and most important advantage, however, is the absolute control which it affords in governing the fires, and this point will appeal especially to those power houses subject to sudden and rapidly changing loads. As an illustration of this may be cited the power house recently erected to operate the Belt Line tunnel road, in Baltimore, Md. A great part of the time there is no load on the power house, as it is only operated when there is a freight train to be hauled through the tunnel. The manner in which the load is handled is as follows: The boiler room is supplied with blowers in place of stacks, and a slow fire is kept constantly under each boiler. When a telegram is received that a freight train is approaching, the blower is started and on the arrival of the train, steam has been raised in sufficient quantity to supply the great demand put upon the boilers. This illustrates the extreme flexibility of the system and it would be difficult to handle this load in any other manner. Economizers are operated with great efficiency in connection with an induced draft as this system permits the flue gases to be robbed almost entirely of their heat, since it is not necessary to have a large quantity of heat in the flue gases in order to create a proper draft.

Passing from the steam generating system to the engines, we find as a connecting link, the system of piping. In regard to the general plan of the piping, opinion is very much divided. Some favor a single header with leaders to the engines. Others claim that a complete duplicate system is necessary, so that a failure in any part of the system need not cause a serious stoppage. The objection to a duplicate system is the greatly increased cost. In the installation of a duplicate system, it is only human that the material and workmanship employed will be cheaper than if a single system were employed, because it is reasoned that if one side breaks down, there is always the other to be depended upon. The other side, however, is often never used until a case of necessity arises, and on account of this very lack of use, the valves and joints are apt to be found leaky and in bad condition when suddenly put in operation. A compromise system has been used in some cases in which all pipes are duplicated, each side, however, having one-half the capacity required, necessitating the use of both sides at all times. In case of accident to one side, the other half of the system may be used, at a disadvantage, of course, by increasing the steam pressure. The best plan, however, seems to be to use a single header divided at convenient intervals by valves according to the size of the plant and the number of units employed, and in laying out the system to use only the best valves, material and workmanship. The power houses having the least amount of trouble with their piping are those having a simple system, probably because it is natural to erect better, and take better care of something which is in constant use, than something which may easily be dispensed with. All steam and hot water pipes should be covered so as to prevent as much as possible loss of heat by radiation and consequent condensation of the steam. And in this connection it should be noted that there is a great difference in efficiency in the different kinds of pipe covering. Tests have shown that the magnesia plastic and sectional coverings and the asbestos fire felt covering give the best results.[1] A water separator should be placed in the leader to each engine. It should be large in size, and placed as close as possible to the engine. A number of patented separators are on the market, but very good results may be obtained by the use of a simple, large tank with the steam entering at the side and leaving at the top and supplied at the bottom with a connection to a steam trap to catch any water collecting in the separator.

OHIO. The County Commissioners of Crawford County granted to W. E. Haycox, president of the Fulton Truck & Foundry Company, of Mansfield, Ohio, and Fred. B. Perkins, of Toledo, the right to construct and operate and maintain an electric road from Bucyrus to Galion. Work will be commenced in the early spring. All business pertaining to said road will be referred to W. E. Haycox.

TRACK AND TRACK JOINTS, CONSTRUCTION, MAINTENANCE AND BONDING.[1]

BY M. K. BOWEN.

AFTER signing a contract to tell my associates in business how to construct and maintain a street railway track, I began to cast around for data bearing upon the subject, and found that the life of a rail was measured by the wearing out of the head, and less than 12 per cent. was worn away before we sold the old rail for scrap; hence the deduction that the point of contact between the wheel and the rail, in other words, the bearing and wearing part of the track, was the most important consideration. I asked a wheel manufacturer why wheels of street railroad cars were made conical or beveled shaped instead of flat. His answer was, "To draw out of the mold of course." Not being satisfied, I asked a steam railroad man the same question. He said it was for the purpose of compensating on curves for the further travel of the outside wheel.

If I had asked a street railroad man the same question, he would have promptly and correctly answered (even if he did not know and had to guess) that the bevel on a car wheel was for the purpose of centering the car on the track, providing a means for a lagging wheel to catch up again, maintaining the axles of the car at right angles with the rail of track. The foundry man was wrong, because we all know that flat wheels can be made. The steam railroad man, when he answered, had in mind his 10 degree maximum curve, but in applying his answer to our conditions he was wrong, because on a quarter circle curve of 50 feet radius, 30-inch wheels, the outside wheel is compelled to travel 7 feet 4¾ in. farther than the inside wheel, and the absurdity of the bevel of ¼-inch on a two-inch tread compensating for this travel, and preventing slipping is readily apparent, as it would require a bevel of 1 11-16 inches in a two-inch tread to compensate for the difference in travel of the wheels. The effect of the slipping of wheels on curves is clearly shown by the brightness of the rails, showing abnormal wear.

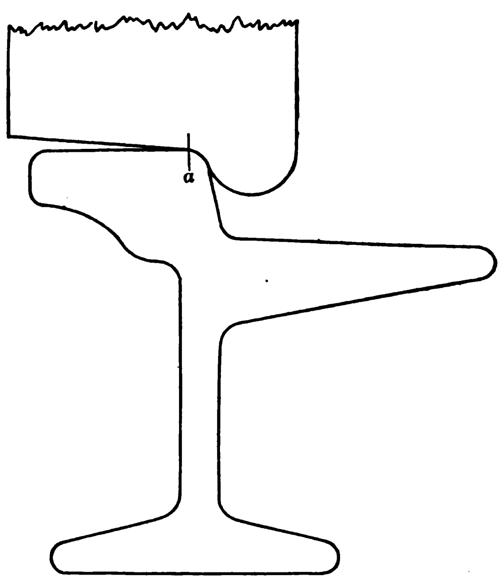

FIG. 1.

Take first a conical wheel running on a rail the surface of which is level. Referring to Fig. 1 we note that the rail and wheel make contact only at the point shown at (a). This is the state of affairs when the rail and wheel are new. In a few months, if we again examine our wheel and rail, we will not find them the same as when we first looked at them. We now observe that the wheel is badly worn next to the flange, while the inner edge of the head of the rail has flattened to a considerable extent and worn down. Both the wheel and the rail are doing their best to come to a common bearing surface, but it is at the expense of scrap wheels, of which only half of the tread has been worn through the chill. It is quite plain that the rate of wear must be enormous at first for the whole weight of the car is brought to bear upon a very small surface at almost a point I might say. This rate of wear steadily decreases as the surface of the rails and wheels wear themselves away until the contact between the two is a line the whole width of the rail, and not merely a point. But long before the surface of the rail has conformed to the surface of the wheel tread, where the best form is attained, the head of the rail has lost a large percentage of the metal allowed for wear, and as wheels wear faster than rails, it has taken in some cases thousands of quickly worn out wheels to bring the rail to its final and best form.

Figs. 2 and 3 show sections of the rail now in use on the State street, Chicago, cable line, the height of the head being 1 3-16 in. The first rail put in State street, Chicago, had a head ¾ in. high; this was increased to 1 in., and later to 1 3-16 in.; it is beveled to conform with the bevel of the car wheel for ⅔ of its section from gauge line across head.

Many will ask, no doubt, if there is not a slipping of the wheels on the rails, due to the unequal diameter of the wheel at all points. There is, imagining the wheel divided into three parts at right angles to its axis (Fig. 2) and each piece free to move by itself, and whose diameters are situated at (a), (b) and (c), respectively, it is quite evident that as the portion (a) makes one revolution it will travel over a less distance than the portion (b) would, and similarly the portion (c) will travel farther than the portion (b) in one revolution, but on account of it being all one the portion (a) travels farther than it otherwise would, thereby causing it to slip; the portion (c) would travel a less distance than it otherwise would, thereby causing it also to slip.

The above is based on the supposition that the car would move a distance equal to the circumference of the wheel at the point (b) in one revolution of the wheel. But this waste of power due to slipping is very slight, for, considering the coefficient of friction as .15, we find that for a ton mile the energy lost by this slipping is .0104 horse-power; so small in fact, that on account of other advantages it may be ignored.

The experience of the Chicago City Railway Company, who first tried this form of head, has been that it saved wear of both rails and wheels, increasing their life by about 35 per cent. Why not in building a track put in rails which are beveled to conform to that of the car wheel at the first, and not spend time and money wearing the wheel and rail down to fit each other?

The question concerning the composition of the rails is one to be considered here also. How does the composition affect the life of the rail? The number of starts and stops made by cars on electric railways are enormous as compared with those on a steam road. The result is the wheels slide, sometimes spin, and this, together with the sand and dirt on the track is a cause of great wear on both the wheels and rails. This wear, together with that due to other causes, might be greatly reduced by proper composition of metal.

I give below a table gathered from different sources showing the composition of metal advocated by experts to-day:

	A.	B.	C.	D.
Carbon	.45- .55	.55- .60	.50	.40
Manganese	.80-1.00	.80-1.00	.75-.95	.01
Phosphorus	.06 not over.	.06 not over.	.09	.11
Silicon	.15- .20	.15- .20	.10	
Sulphur	.07 not over.	.05 not over.	.07	.06

Rail.	Carbon.	Phosphorus.	Silicon.
70-pound Tee	.43—.51	.085	.10
75-pound "	.45—.53	.085	.10
80-pound "	.48—.56	.085	.10
90-pound "	.55—.63	.085	.10
100-pound "	.62—.70	.085	.10

It would seem that the harder a rail becomes through its composition and the process of rolling, the longer it would wear. As regards this, Mr. Moxham of the Johnson Company says: "There are two schools—First, those who advocate a low hardened and ductile material as being of the greater wear. Second, those who advocate the greatest possible hardness, regardless of brittleness. For many years without taking positive grounds, I have leaned to the former class, but the experiments so far made have demonstrated to me that neither class is correct—that the correct solution lies between the two."

I come now to what has been heretofore the weakest part of track construction, namely, joints. What we want is some method of keeping the rails from pulling apart at the joints, due to contraction and spreading outward at joints, and the shape, due to the outward pressure, of the car wheels, and from bending down at the joints, due to the pounding and weight of the cars. The joint I have used for the past year is a cast welded joint. This has been found to give perfect satisfaction as a joint; it is strong and substantial, as has been proven by its holding under the extreme changes in tem-

[1] Paper read before the American Street Railway Association, St. Louis, Oct. 20-23, 1896.—Abstract.

perature for which Chicago is noted. Seventeen thousand joints were put in in 1895, and of those only 154 joints were lost. The joint in comparative tests has been shown to be far stronger than the rail itself, and such breakages as have occurred were due to a flaw in the metal. The metal cast around the joint has eight times the cross section area that the rail has. Hence, considering steel as four times as strong as cast iron, the joint is twice as strong as the rail.

It has been found in some cases where this joint was used

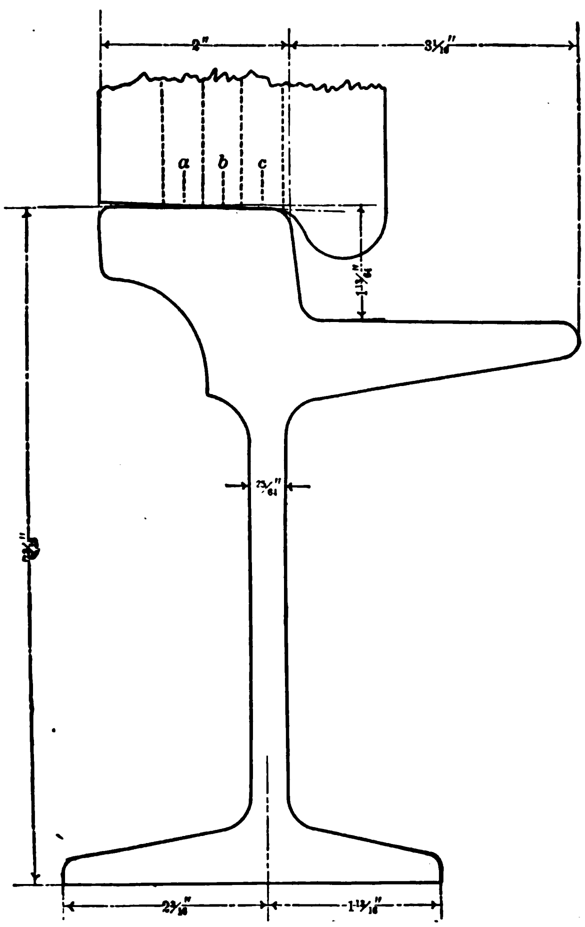

FIG. 2.

at crossings with other tracks, the tracks were apt to be pulled out of shape through the changes of temperature. To overcome this the joint nearest the crossing should be anchored in a substantial manner. The method of making the joint is as follows: The rails at the joint are scraped and brightened, a cast iron mold is placed around the joint, making a tight fit; into this the molten iron, 25 per cent. scrap, 25 per cent. soft and 50 per cent. hard silicon pig is poured. The metal in contact with the mould begins to cool and forms a crust while the interior remains molten. This crust continues to cool and at the same time contracts, forcing the moulten metal strongly towards the center, which makes a solid and rigid joint. The top, or bearing part of the ball of the rail is afterwards filed off perfectly level so that it is very difficult to detect a joint by riding over it or looking for it. Upon breaking a joint which has been well cast, three spots will usually be found where amalgamation has taken place between the rail and cast portion; one on each side of the web and the other on the bottom. These spots are from 1½ in. to 2 in. in diameter. There has been some discussion as to its being a bond for carrying electric current. I cannot recommend it with certainty, as there are occasional joints which I have taken off where no amalgamation has taken place whatsoever, thus destroying the effect as a bond of all joints in that line of track. To overcome this difficulty I have adopted the plan of bonding all joints. However, future experiments and care in the casting of joints may develop their efficiency as a bond.

Fig. 4 shows a section of the track construction used by the Chicago City Railway Company.

The cost of one mile of double track with paving for 18 feet in width of right-of-way, as above specified, based on Chicago prices, would be as follows:

283 L. tons 9 in. rails, 90 pounds, at $33.00	$9,339
4,224 white oak ties, 5 in. x 8 in. x 7 ft., at 38c	1,605
352 cast welded joints, at $3.50	1,232
1,760 tie rods, at 15c	264
33,792 spikes, ½x½x4½, at 1c	338
42,240 ft. of wood filler, at ½c	2,112
Labor at $1 per l. ft. of D. B. T.	5,280
10,560 sq. yds. cedar block, 30c	3,163
146 sq. yds. sand, at $1.25	183
445 cu. yds. crushed stone, at $1.50	668
10,560 sq. yds. gravel and dressing, at 8c	845
10,560 sq. yds. Hemlock boards, 2 in. thick, at 8c. sq. yd.	845
	$25,879

If granite had been used instead of wood block the cost would have been $12,708 more.

Upon organization depends the successful maintenance of the track, and one which I find gives the greatest efficiency is that the system is divided up into sections consisting of twelve miles of double track each. Each section is put in charge of a working foreman who is to keep and maintain and repair as cheap as possible, and who is held directly responsible for the condition of the track at all times. He has under him as many laborers as are required to keep his division in repair.

The question as to the right time to reconstruct a track is one of the greatest importance, as it often involves the expenditure of thousands of dollars. The task of solving this question was brought before me not long ago concerning the State street cable track, which had reached a deplorable condition. Taking the track master with me we rode over the line and, as street railroad men often do, guessed that it was time to re-build the track. This involved a very large expenditure, and it would be an expensive guess unless correct, so to ease my conscience and make sure of my guess I had run over the line a car weighing 8,665 pounds, attached behind a grip car by means of a recording spring balance called a dynamometer. This test car was then run over a track newly made at the same speed as over the old line; the dynamometer showed that it took 13.75 pounds more pull per ton to haul cars over the old line than over the new. The average speed of cars on this street is 12 miles per hour. The excess horse-power required to haul one ton was .44, and the excess cost of hauling one ton one hour was $.0088. The num-

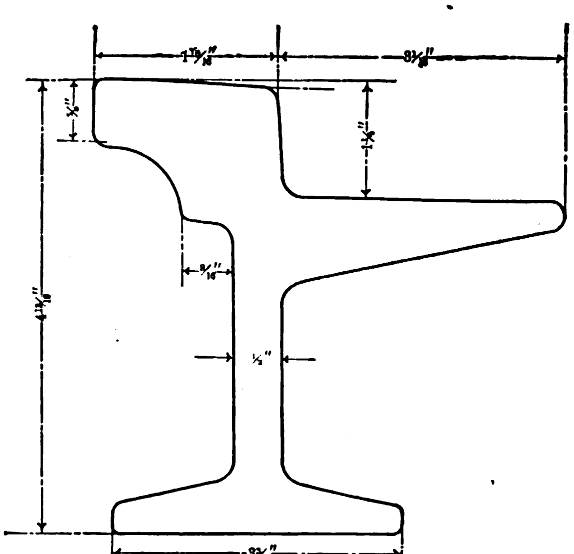

FIG. 3.

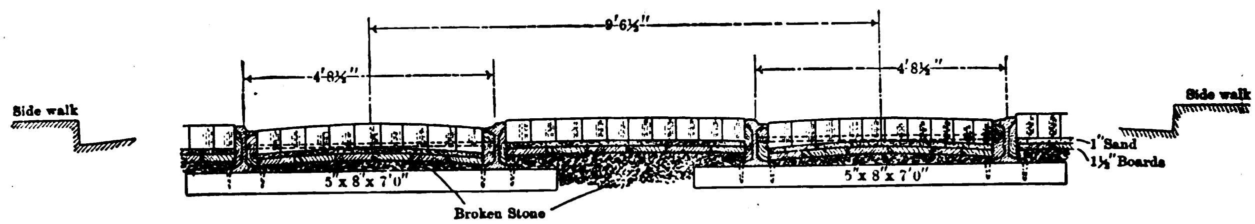
ber of tons hauled one mile per year on this track was 4,147,537, and the time required to haul one ton one mile was five minutes; and 45,147,537 tons hauled at a given speed for five minutes is equal in work done to 3,762,295 tons hauled at the same speed for one hour. 3,762,295 multiplied by $.0088 equals $33,108, which is the excess cost per year for hauling cars on account of bad track. It is estimated that the new track with cast joints will last twelve years, and as there will be no low joints, the draw bar pull will not increase much until the rail is worn down sufficiently to allow the wheel to run on the flange, so the annual saving will be nearly $33,108, during the life of the rail, and the total saving will be $397,276, which in twelve years will pay principal and interest on $293,444, which is the amount we could profitably expend

in repairs. The actual cost of re-building this track was $61,670.

This caused me to think up some scheme by means of which dynamometer or power ratings could be taken and automatically traced on paper, showing the condition of the track at all points, showing faults of gauge, level, or joints; showing faults and excess power in consequence of faults, side by side, thus placing a value on faults, and then instead of representing faults and excess power in inches or foot pounds, make the instrument show them in dollars and cents per ton of load when capitalized, which would show, multiplied by the ton miles on any road tested the amount that could, with good management, be expended on track reconstruction, or re-building. The apparatus devised for this purpose is what we call an indicator car. A description of the construction and method of working might be of interest to not a few, for I do not know of another in use by a street railway company, and found only one other, although very dissimilar, in existence on a steam road, after I had the plans of mine finished.

The results shown by it are high and low rails, low joints, gauge, drawbar pull and the variation of the track level. Each one of these results is automatically platted on paper 18 inches wide. The car consists of a platform 8 feet by 10 feet, mounted on a single truck, no springs being used. Midway between the two end axles is one which is fitted with wheels which record defects of joints or gauge. After use and calibration of instrument it will be more valuable and the dynamometer will not be required, as any man using this car constantly will become so accustomed to the value of defects that a glance at the profile will tell him the money he may, with judgment, spend for rebuilding a track or repairing it.



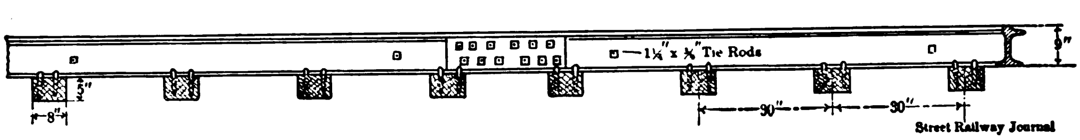


FIG. 4.

The dynamometer consists of two draw bars, one at each end of the car, and extending beneath the platform to within a distance of about one foot of each other. Between the two adjacent ends of the draw bars a spring is placed, and the amount of pull required to draw the car along the track in either direction is recorded by a recording arm, which is connected to the spring with a wire. The apparatus for showing the variation in the level of the tracks is mounted on the platform and consists of two cups of mercury (having a connection between them by means of a pipe) and into which dip two plungers connected to a recording arm. The paper on which the record is taken unwinds at a uniform speed of 1 ft. per 1,000 feet of track. The car weighs 3,865 pounds. The car is fastened to an ordinary car, which is drawn over the tracks by horses (or any motor car) made to go at as even a speed as possible. The results shown by a recent test trip are very interesting to compare. (Various diagrams were added, showing the manner in which the dynamometer car records inequalities of the track.)

We find from the data obtained by use of this car that we could afford to expend $7,383 per mile to repair the old track. The estimated cost of repairing this track, leveling and casting new joints, is $1,740 per mile. The track maintenance during the year 1895 for 184 miles of track cost $158,217 and represented 17.75 per cent. of the total operating expenses. This excessive cost is largely due to a partial or complete rebuilding of many miles of track.

In conclusion I wish to acknowledge receipt of facts and data bearing upon the subject of this paper from Mr. Moxham, Mr. Augustine W. Wright and Mr. Mead; also to thank Mr. W. G. Price for valuable aid rendered me in designing and perfecting the details of indicator car. (The car was open to be inspected in the exhibition room during the convention.)

HOW CAN THE REVENUE OF STREET RAILWAYS BE INCREASED? [1]—I.

BY C. DENSMORE WYMAN, COMMITTEE.

The text that is handed to every general manager, superintendent and directing official of a street railroad company when selected for his position, reads "Increase your receipts; decrease your expenses," and I suspect that there are few if any untried paths leading towards the consummation to which such a text points.

Almost every company, by virtue of its location, the character of the people it serves, the specific requirements of its charter, and the general conditions surrounding its operation, is obliged in adopting any special method for increasing its revenues, or in introducing changes in the conduct of its business to take into consideration these local conditions, and these are as various as are localities of operation.

Our regular line of customers we have always with us, and while their pleasure and comfort is to be cared for, what may be termed the transients, the occasional purchasers of our wares, are to be sought after, catered to, gathered in to increase the regular revenue. In the line of merchandizing, we have rides for sale, and all companies, I doubt not, feel at times that they are overstocked; for the disposal of this stock to attract to our counters not only those who must needs purchase, but as well the wandering, uncertain shopper is desirable.

Imitating the wise merchant, we must seek to place our wares before possible customers in the best condition. We should see to it that what we offer is not shopworn, but is made to appear alluring and enticing. Every car should be a fine looking show window, inviting not only to the regular business traveler, but to the tourist and sightseer as well, who does not know whether to buy a ride or not, and who needs an invitation. Our salesmen are to be as dapper and obsequious as the well drilled and groomed counter-jumper of the merchant's emporium, and all the surroundings of our business should be based upon the principle that to please is the way to get custom and retain it.

Judicious advertising is, I believe, usually regarded as the coin medium of a merchant's business. What ought a railroad company do in this direction? Some of us have doubtless felt that the presence of the cars in the streets was sufficient advertisement of the company's readiness to do business, but it seems to me in this matter we may continue our imitation of the merchant in the conduct of his business. I venture to point out two or three methods of advertising which I think may be successfully employed. First of all, what may be termed "Personal" advertisements through officials and employés.

Every person connected with the road should have it thoroughly impressed upon him when he takes a position that his first and primal business is to "talk up" his company at all times, under all circumstances and to every one with whom he comes in contact. It too often happens that a passenger riding upon a car expresses some criticism to the conductor, motorman or to an official, and instead of receiving an assurance that he must be mistaken, that it is quite impossible that an error such as that of which he complains could happen, or at best that it is surely not the fault of the company, his complaint is readily admitted as just, nay, he is almost con-

[1] Read before the American Street Railway Assoc. St. Louis, Oct. 19-23, 1896. Abstract.

gratulated upon his cleverness in finding weak spots in the company's armor.

Often, even in the office and among the heads of departments, criticism is met in a cringing and apologetic form that serves to make it more positive in the critic's mind that his fault-finding is well founded. However ready we may be to confess to ourselves that all is not just what we may desire, that our company is lame in some respects and halting in others, it is certainly the poorest of policy to make such an admission a matter of public notoriety.

Within the circle of our own counsels, the severest criticism of failure to reach the standard we have set for the men or apparatus may be indulged in, but to the public no intimation of our self-condemnation should ever be permitted to go. Of course, there are times when it may be proper and necessary for the manager to admit that an employé has made a mistake, or that some portion of the system is defective in operation, but the general trend of sentiment to be exhibited to the public on the part of the entire force, from the manager down, should be one of pride in the company, and a habit of talking up, praising, glorying in the institution with which they are connected, should be made a matter of cultivation on the part of the heads of departments, and insisted upon by them from all in the service.

Advertising by the use of printed matter may also be employed with advantage to place before the public. The street railway company's inducements, and publications of this sort are of especial service to strangers and tourists visiting the city in which the company is located. I have found a little folder, upon one side of which is a little map showing the various routes and points of interest in and about the city is printed, with other pages descriptive of the pleasure grounds, parks, cemeteries and other places of resort, together with the time tables of the different lines of our own system, to be of great advantage. These folders, placed at the different hotels, railroad depots and steamer docks, were eagerly sought for by visitors, and distributed upon the cars by the conductors, were very largely used by the patrons of the lines for reference. Our own company issued as an experiment about 50,000 of such folders at the beginning of the past summer season, and the call was so great for them that another issue was found to be justified in a very short time.

If a company's lines have some central point of intersection, from which different routes radiate, signs, giving directions and places to which cars leaving these principal points go, may be of value and serve oftentimes to gather into the company's treasury nickels that, without the information so conveyed, would remain in the pocket of the undecided sightseer. These signs are not expensive and painted upon glass and illuminated they present a handsome appearance. They can be readily attached to trolley poles and lighted from the trolley current. They suggest progressiveness, and an up-to-date policy on the part of the company.

In the endeavor to increase business many street railroads have of late become purveyors of public amusement and as proprietors of parks and outing resorts located upon their lines have gone into the show business with more or less success. In studying this new departure on the part of street railway managers, we recall the Latin adage "Ne sutor ultra crepidam," and quote it as applicable to the inclination of railroad companies to embark in amusement enterprises in connection with the duties directly growing out of the operation of their respective roads.

From such statistics as we can gather, the net revenue gained by companies who have gone extensively into the show business has been in many instances inconsiderable, in some cases a loss has resulted, and but few report substantial profit. Whether to invest in matters of this sort is, however, so much a matter conditioned by the local surroundings, the improvement of unfrequented lines and the ever changing taste of the public, that no general rules for universal guidance can be formulated. We are inclined to say to the general proposition, "Don't go into the amusement business if you can help it; subsidize those who have made that line of life their study, and give over to them the profit of the enterprise other than that gained by the transportation of visitors to their spectacle or resort; "stick to your last, shoemaker, for you have quite enough to do to attend to your own business."

The specially illuminated trolley car for evening excursions is a species of advertising which pays in every way. It can be made a vehicle of pleasure not only to those who pay for its use, but as well to those who delightedly watch its artistic light effects from along the line over which it passes. We believe it tends to popularize the service.

In the smaller cities, the use of the newspaper columns for items of proposed change in car house, equipment, trackage, etc., extensions and improvements ought not to be disregarded. After the wise method of an advance manager for a show, frequently the newspapers should be given news of the proposed improvement about to be entered upon by the railroad company, some new addition to its service, something that will make for comfort or convenience of passengers, or of the proposed opening of some territory hitherto unoccupied. All this tends to the maintenance of interest in the company and the stimulation of a local pride in its doings. Daily newspapers mould public opinion and are especially influential in the smaller towns; they should, therefore, be made vehicles as often as possible of announcements concerning the growth of the railroad and they should be used to make plain the company's anxiety to please the citizens, and to promote the reputation and the growth of the city in which it is located.

We now pass to the consideration of other methods for the increasing of our revenue with the final advice; advertise the goods of the company as the best and cheapest to be had anywhere, on all occasions and always.

In the line of making more attractive the service of a street railway company and therefore tending to increase its patronage, the establishment of a liberal transfer system is worthy of consideration. I am aware that the subject of transfers is one regarding which street railroad men differ widely, and for and against which arguments of the strongest kind are at hand. The difficulties inherent in the wide distribution of transfers, especially upon a large system of railroad lines, are many, among which the liability of the conductor to make of the transfers an opportunity for peculation and a cover for fraud is most prominent. While in many cities a transfer system has been made a subject of municipal enactment especially in the case of recent charters, and thus would seem to have come to stay, in some form or to some extent at least, it is for us to determine if possible whether or not the transfer system is a profitable measure for a street railroad company, and thus where it does not involve other considerations whether or not it ought to be readily adopted.

Inquiries made of various railways touching this point led me to the belief that this question is to be answered in the affirmative. This is especially true of roads making quick time by means of cable or electric power. When a passenger to go a few miles required two or three hours, the transfer system was not specially beneficial or attractive to him, if a business man, who could not spend the time to avail himself of the privilege it gave of long distance riding. But now that six miles an hour rate has been increased to twelve, even in the crowded portions of many cities, and to a much higher rate upon suburban lines, longer distances can be traveled by passengers, visits are made possible within a reasonable length of time to widely separated portions of a city and the only impediment to greater through business between such points is often the necessity of paying two or three fares for such a visit or journey. This impediment once removed, an increase of travel is invited, and a ride upon two or more lines of cars is provided within the same period of time that a single ride was formerly given under the system of horse car traction.

It is, of course, a fact that the hazard of accident to a passenger is increased in proportion to the number of lines which he traverses on a single journey, and this with the labor attendant upon the collection and registry of his fare, and his care while on the cars would perhaps be only fairly paid for by a fare upon each line he may use; but the larger number of persons induced to ride by a very free system of transfers upon a system extending to different quarters of the city of its operation, we believe will compensate for such extra hazard and labor even if it is assumed for a single fare.

This is especially true upon holidays and excursion lines. Almost every street railroad which controls a number of lines in a city has located somewhere upon one of them, and perhaps upon several, points for pleasuring, and to gather from all parts of the city the mass of the people and take them to these places of interest is important. The laboring man who desires to take his wife and children of a Sunday to some outing place, if he can reach that point from his distant home by transferring for a single fare each, is likely to take the journey. If, however, he must needs pay two or more fares of five cents each to get to the point of his pleasure, he remains at home or reduces the number of persons included in his party.

Another favorable argument for the transfer system is the fact that it leads to the settlement in the suburbs of many persons who would not venture so far from their places of business were they not assured of being able to reach them by the payment of a single fare, and this getting of people from the congested parts of a city to its environs, thus assuring the railroad company of their continuous patronage, is most desirable from a railroad standpoint. For these and other reasons which might be mentioned, we believe that it may be broadly stated that a liberal transfer system increases both the popularity and revenue of the street railway company by which it is adopted.

It is quite impossible, with the limit prescribed for this pa-

per, to discuss the question, as fully as its importance deserves, whether it will be found generally profitable for an urban street railroad company to sell tickets good for a fare at a reduced rate by purchasing in quantities, or whether the best interests and profits of a company are secured by adhering to a fixed cash fare of five cents at all hours and times. When the almost universal motor for street railroad use was the horse and the mule, it was a generally accepted fact of experience, derived from the results of street railroad operation in this country, that five cents for an average ride was as cheap as a company could charge and do business at a profit, and was at the same time a most reasonable one for the users of the cars. Thus the charters of nearly all street railroads granted during the horse car period provided that the nickel should be the limit of their charge for a fare.

It is true, as some of our would be reformers in municipal councils and legislative halls loudly announce when seeking political preferment and a reputation for being what they are pleased to call "friends of the masses," that with the change of motive power from horse to electricity or to cable, the street railroads can now afford to reduce, by the sale of commutation tickets, their fares from five to four cents, or even three cents, and still have left a fair margin of profit upon their investment? The cost of transportation of a passenger upon any individual road can be made a matter of almost exact figures, and we believe that when the items properly to be included in such a computation are carefully set down the relative cost of transporting a passenger by horse car, as compared with that of electricity or cable, will be found to be such that any reduction in the fare cannot be made without positive loss to those who have put their money at risk in the enterprise. It is true that with the advent of quicker transit the gross receipts of most all companies that have changed from horse to electricity or cable cars have greatly increased. This is undoubtedly due to the fact that a longer distance can be traveled in the same length of time, and the other fact that congested portions of the city have been relieved and the dwellers therein sent to the outskirts, thus creating new centers of population and business, and, further, that with this change of motive power have come more convenient and pleasanter facilities for transit, inviting not only more of the usual business travel, but an increase in transient, pleasure and excursion riding as well. But to an equal extent with the increase in gross receipts has the expense of installation and operation kept pace, and so preserved in net the former figures. The cost of the reconstruction of a system necessitated by the change of cars and stations, tracks and extensive machine shops, tools and new equipment are the first large items of this expense, and to these are to be added the expense necessitated by costly repairs in maintenance. Further must be added the increase in wages of employés, engineers, mechanics, electricians and skilled machinists, whose employment is necessitated by the new régime, either because they receive more money for their labor or work less hours for the same wages.

A fact that must not be overlooked in this connection is that of the growing demand on the part of the public the company serves, for greater luxury and elegance in the matter of appointments of travel. Our cars must be handsomely and more expensively furnished than were those our patrons were satisfied to use a few years ago. Not only must they move faster, but they must be better lighted, better heated and generally better fitted up for the safety and convenience of passengers than were those accepted formerly. The supplying of these demands has been attended by an increasing operating and maintenance expense. Thus while an increase in the patronage of the road has been in most cases evoked by the change of motive power, we believe it can be safely asserted that little decrease in the expense per passenger carried has been made. This conclusion is brought out by the results attained on the operation of electric and cable roads in the majority of the cities of the country in the past few years, as shown by their reports.

A careful study of the published reports will make it apparent even with the depreciation accounts eliminated that the cost per passenger upon electric or cable roads is not less than that on the horse car which they succeeded. As yet as far as urban roads are concerned we cannot discover that on the whole there is any more profit in a well managed electric or cable street railway than there was in a well-managed horse car road; and we venture the assertion that to-day less of profit in the form of dividends derived from receipts of operation, is being distributed to shareholders in the modern electric or cable roads, proportional to the business transacted than was given them by the old-fashioned horse car companies. From the books and statistics of the majority of companies no favorable arguments are to be drawn for the reduction of fare.

It must also be borne in mind in the consideration of this question that while it is an easy thing to reduce the fare of a road, it is by no means as easy to return to the old rate in case such a reduction results in a loss and proves a failure. Unlike the merchant who may raise or lower the price of his wares and for a day may attract a crowd to a bargain counter in the hope that there may be a profitable sale effected to-morrow, the loss occasioned by a reduction in street railroad fares cannot afterwards be regained by a corresponding increase above the rate originally receded from. Higher than the five-cent point we may not go, and if once lowered, even with the plainest statements of the loss it entails before the public, an attempted return to the old rate is provocative of dislikes on the part of the patrons and is almost sure to set in motion legislative action designed to compel the continuance of the lower fare. Such a reduction, therefore, since it is likely to be permanent and continuous, whatever may be its effect on the company, is made at the risk and in the face of the various contingencies, which surround the business of a road which must maintain an uninterrupted service through fat years and lean years, through times of depression and dullness, when competition and an uncertain labor market may make inroads on its income, and therefore is, to say the least, decidedly hazardous.

By the advocates of reduced fares it is ordinarily assumed that the cheaper rate will invite a sufficiently greater number of new riders to make good the difference in income by the lessened price to each. But we believe that a computation based on the earnings of almost all companies at the five-cent rate to ascertain how many more passengers, say, at a four-cent fare, would have to be carried to make good the difference between the two rates together with the increased cost for the more carried, including the risk assumed of accidents, will demonstrate the fallacy of such an argument.

The old adage "quick sales and small profits" will not apply in this matter. A less reduction than one-cent per fare will hardly be acceptable or sufficiently attractive to induce a more liberal patronage of the cars. But the reduction of one cent in five entails the loss of a higher percentage of the original price and which is much greater than the ratio of original profit. The fallacy of such a reduction is well stated in the editorial columns of a recent issue of the "Street Railway Journal." It is there remarked, "A loss of twenty per cent. of their gross receipts following a reduction of fares from five cents to four would send half of our best paying roads into bankruptcy and would so cripple the others as to make improvements in service practically impossible. A further reduction of twenty per cent. would make them all shut down."

For want of time we have not made mention of the serious danger to a company of loss through peculation by the conductors where the cash fares upon the road are fixed at one rate and commutation tickets are sold and received at a less rate. If the value of an article consists in the cost of its production and its exchange, we think in the light of present street railroad operation that the standard five cent fare is a just and reasonable equivalent for an average ride upon a street car, and that no reduction therefrom is advisable or expedient.

FIFTEENTH ANNUAL CONVENTION OF THE AMERICAN STREET RAILWAY ASSOCIATION.

THE fifteenth annual meeting of the American Street Railway Association was held at the Auditorium Building, St. Louis, Mo., October 20-23, 1896. President H. M. Littell, of New York City, presided, and Secretary Pennington, of Chicago, assisted. The meeting was opened with an invocation of divine guidance by Rev. P. G. Robert.

President Littell introduced Mr. Charles Nagel, acting mayor of St. Louis, who delivered an address of welcome.

THE PRESIDENT announced the next business to be the calling of the roll, which was accordingly done, and it was found that seventy-five companies were represented.

The address of the president being next in order, President Littell delivered his inaugural address.[1]

On motion of Mr. Green, of St. Louis, it was voted that the address of the president be printed separately, one thousand copies.

MR. BAUMHOFF, of St. Louis: Mr. Chairman and Gentlemen—This meeting marks a new era in the history of the American Street Railway Association. Fourteen years ago Mr. H. M. Littell, then general superintendent of the Louisville City Railroad Company, and now vice-president and general manager of the Buffalo Street Railway Company, conceived the idea of the benefits which might accrue to the street railway managers by the formation of an association of this character, and after a conference with a number of friends, it was deter-

[1] See page 419.

mined to call a meeting for organizing what has since developed into one of the grandest associations in this country. (Applause.) Accordingly, invitations were extended to representative street railway managers throughout the country to attend the initial meeting in the city of Boston, in the month of December, 1882. Like the spokes extending from the hub of a great wheel, this association has spread throughout our great land. We are in a new era, because we have eliminated the discussions of the care and feed of horses, the construction and ventilation of stables, and other sundry annoyances which at that time tended to make the life of a street railway manager anything but pleasant. It is a new era, because you have met for the second time in our midst, and we proudly point to the fact that we have transformed our last animal traction road to one operated electrically. Mr. President, in behalf of the Chicago City Railway Company, I present to you this handsome gavel, made of the hardest and most durable wood, inclosed in this handsome box made from the sill of a car which has for many years done service on the Chicago City Railway. May this convention, as it is called to order by the rappings of this gavel, pass into the annals of history as one of the most pleasant and beneficial gatherings of this character. (Applause.)

PRESIDENT LITTELL: This, gentlemen, is indeed a very agreeable surprise, and I am in hopes that it will be sufficiently large to preserve order. I thought when I was elected president of this association that my position would be such that I would look down upon all of you, but I find upon entering this hall, that you all look down upon me; the fact is, I think you have got me in a hole. (Applause.) I am pleased with the prospect that with the assistance of my friends it will be possible for me to preserve order with this beautiful gavel.

MR. BEAN: Mr. President, as Mr. Baumhoff has pleasantly reminded us of the Boston meeting in 1882, I would ask that every gentleman present who was at that meeting, will rise for a moment. Messrs. Green, of St. Louis; Smith, of Troy; H. H. Littell, of Buffalo; Rugg, of Pittsburg, and Bean, of St. Joseph, Mich., rose.

The secretary then read the minutes of the meetings of the Executive Committee held during the year, and closed with the report on membership, showing that the membership in October, 1895, was 173 companies; eight new companies had joined the association; three had become consolidated; one company had withdrawn, and thirteen companies had been dropped for non-payment of dues, leaving the present membership 164 companies.

The committee referred to the fact that at the beginning of the present fiscal year the association was in debt $6,000, and that this indebtedness had been cancelled, and the income during the forthcoming year would be about $6,500, which would enable the secretary to enlarge the scope of the work of the association, it being contemplated that a monthly bulletin shall be issued, containing information of value to the members.

THE PRESIDENT: The first paper on our list is that by Mr. M. K. Bowen, superintendent Chicago City Railway Company, on "Track and Track Joints, Construction, Maintenance and Bonding."[1]

MR. ROBERT McCULLOCH: With regard to the carrying of the current over a welded track without bonds, we have one piece of track which is thirteen miles long and all welded together, the most of it being 60-foot rail. We have not an ounce of copper nor a bond of any kind on the entire track. We have made tests of all sorts, with delicate instruments, graded to the thousandth part of a volt, tested as long and as short lengths as possible, sometimes a mile and sometimes a single joint, and have found in most instances that the carrying capacity of the joint was greater than that of the rail at any other place. We have found no necessity for bonding, our contact is perfect at the extreme ends of the rail, and I do not believe it is necessary to bond a welded track. All the tests we have made have been on track that was laid about ten months since. The tests were made about two months ago, so that the oldest joints we tested were about six or eight months old. It is cast welding.

MR. SEELY: I wish to know whether it is necessary to own a plant for repairing purposes in case the joints are broken? How do you repair joints after the welding plant is taken down? I know that to weld a mile, or four or five miles, it is not expensive to run a cupola; but it would be in the case of repairing a few joints now and then.

MR. BOWEN: For a small road it would be better to let the contractors repair the broken joints. For a large system it would probably be better to keep a cupola; you are always building more or less track and doing a considerable amount of repair work. A large system is generally building new track, and you could use a machine and make it pay for itself.

MR. DODGE: You spoke of something like 200 joints out of 1,700, which parted. How soon after the casting of these joints did they part; was it very soon after they were welded?

MR. BOWEN: We lost the joints on account of contraction, due to very cold weather, in midwinter. With the first cold snap, the contraction of the rails pulled 154 joints apart. The joints were then repaired, and since then they have gone through the summer the same as the other joints. The joints were cast in midsummer, during the night hours.

MR. SOULLIN: Were most of the joints examined, or simply those found broken? I want to ascertain if the joints were not loosened as well as broken—some of them loosened in some way or other, and which was not perceptible until they were closely examined.

MR. BOWEN: There were 154 remade. When they do part it is for 2 or 3 inches, so that you can see them readily. If there is any oxidation between the joint and the rail, I hardly imagine it would do any harm unless it was sufficient to loosen the cast iron from the rail proper. In that case it would come apart 3 inches, due to the contraction of four or five blocks of steel. In repairing a rail with a space of 3 inches, we saw a piece of rail and cut it in, and recast around the entire two joints in that case. The average cost of the joint is about what the contractor can get out of it—I do not know whether it is a trade secret or not. The joint requires 100 pounds of cast iron, so that you can make your own calculations.

MR. WYMAN: Mr. Bowen says that he uses the bond in order to be absolutely certain of obtaining conductivity in the rail. Will he kindly tell me how he uses it, around the weld or beneath the weld?

MR. BOWEN: We simply bond the track after we cast the joints; a long bond around the weld.

MR. WYMAN: You said just now that when one of those welded joints pulled apart, as they do naturally, they would pull apart 2 or 3 inches. Do you allow for that in your bond?

MR. BOWEN. When the joint pulls apart, in all probability it ruptures the bond. If it does, we put in a new bond. I am not sure that the practice will obtain after the next year or two to come.

MR. GOFF: May I ask what trouble you have in the summer time? I have in mind a track which I think was bonded in the winter—cast in the winter—and in the summer time it seems to be out of line all the time. The car has a waving motion over the track. Do you have any trouble of that nature?

MR. BOWEN: That comes from the casting. Mr. Littlefield, of the Johnson Company, told me that the rails usually delivered to consumers are not sawed square on the ends, but are sawed with the ball on the bias; in other words, that the ball of the rail comes together, and the flange of the rail does not. I have noticed that in laying rails. You will find as you put your mould on to cast the joint that the rails have contact at the ball and not at the flange at all. If you are not careful the rail will do two things—it will go out and it will go up, on account of the majority of the iron being underneath the rail. The contraction in cooling will push it up and push it out. In order to prevent that we put a clamp on the rail when casting it, and push it in a quarter of an inch, and down a quarter of an inch.

MR. GOFF: Did you have this trouble before you cast the track in the manner you just mentioned?

MR. BOWEN: We cast straight joints now; we used to cast crooked ones.

MR. GOFF: What temperature do you find gives the best results? Do you take the season of the year when the temperature is cool, or can you do it equally well in the summer or late in the fall?

MR. BOWEN: I should advise the majority of joints to be cast at night, so that the temperature will be cooler. I advise a medium temperature, a little cooler than the medium temperature for your climate, whatever it is. We like to cast at a temperature of between 40 and 50—somewhere about 50 degrees.

MR. A. JOHNSTON: In the examination of the broken joints by contraction, did you find that the rail pulled out of the cast iron?

MR. BOWEN: Occasionally, but more often on account of our driving two pins through the last two holes of the fish plate. We have supplemented the joint with them. We find then that it tears the casting apart.

MR. JOHNSTON: Then the cast metal is in the mass, but still it is not a homogeneous mass?

MR. BOWEN: It is not in spots. There is a spot on each side, which shows amalgamation.

MR. JOHNSTON: That is something important, because if there are no spots where it is amalgamated to the steel rail you would not have a good electrical connection.

---

[1] See page 422.

MR. BOWEN: I have cut off many joints, and I have found some places where the amalgamation has taken place, and some where it had not.

MR. JOHNSTON: Have you allowed a time test as to the amalgamated metal carrying the return current through the joints?

MR. BOWEN: In welding your rails you would have to be careful to clean the rails, or you would not get a good electrical connection. The 63-pound rail was the lightest we have used, 4½ inches high, which we used on chairs. That is the lightest rail. The heaviest rail is a 7-inch, 83-pound rail. We have used no chairs on the 9-inch construction. In the 9-inch construction we use in our electrical work malleable iron chairs; but this happened to be a steel chair that was used. The bond we use is the Columbia, made by the Roebling Company.

MR. DODGE: I will say that in New Haven, Conn., there are about 1,500 joints there which have been cast on 50 and 60-pound T-rail. Some one has inquired about the cost of these joints. I understand that the man who is putting them in at New Haven on the 50 and 60-pound T-rail is getting $3.25 a joint; the railroad company having to pay the freight to and fro on the apparatus necessary.

MR. H. H. LITTELL: I ask Mr. Bowen, or any gentleman present, if they have had any trouble or experience with the pulling apart of the rail, pulling the rail in two, not at the joint, whether welded joint or put together with splice bars, pulling the rail in two by the contraction?

MR. BOWEN: I think that there were one or two cases on our road of pulling apart. Instead of the fracture being just at the joint, it was some little distance back, probably where the difference between the extreme heat and the ordinary temperature of the rail left a partial fracture; there were only one or two cases.

MR. LITTELL: We have no welded joints in Buffalo. We have the ordinary track laid with 9-inch rail, 94 pounds to the yard. Summer before last we put down some 9-inch rail in hot weather, forcing the rails just as close as we could, leaving them uncovered until the morning. In the morning we drove the rail back, a lot of men with a heavy timber, and drove the rails up as close as we could, and put them together with a twelve-bolt splice bar, 1-inch bolt. We got along very nicely for a time, but winter before last we had one of the rails pull in two, 13 feet from the joint, a 32-foot rail, 9 inches, weighing 94 pounds to the yard.

MR. SEELY: We have had some experience in that line, 90-pound girder rails pulling in two, on an elevation, grade of about 5 per cent. We have this occur every winter; the rails break right in the center. The joints are driven too close together, and the rails are bound to expand in some direction. We also find that with the high carbon rails we are using, it is almost impossible to cut them with the ordinary tools; we require special devices for sawing rails in two. In sawing rails, if you have to turn them over, they will crack all the way down the center, and we are compelled to handle them with the greatest of care.

MR. DODGE: In the cases where you mentioned the rail as being forced up, breaking your joint, did you break that in pieces and make a new joint?

MR. BOWEN: That was not the fault of the casting, and we corrected those cases and have only a few left, pushing them down and recasting. It is faulty work.

MR. DODGE: This concern which is doing this work in New Haven follow this plan, when it is thrown up in that way—and I saw quite a number—they start back 2 or 3 feet and grind it down with an emery iron across that joint.

MR. BOWEN: We do not do that. We file down, but merely for the purpose of getting the proportions of two rails alike, when they are of different heights or something of that sort. We won't allow a joint to be cast and leave it high now. It is necessary with every joint to smooth it off, and we are careful to smooth it off so that it has a perfect surface. You cannot tell it from any other part of the rail. We do this because a joint which once begins to pound is half worn out.

MR. McCORMACK: In answer to Mr. Littell's inquiry about the experience with cast welded joints, our company in Brooklyn put in 2,000 cast welded joints on the 94-pound rail, 9-inch girder, and out of that number there was only one which pulled the rail apart; the rail broke about 4 inches from the end. They have given us very good satisfaction, at least we think so. We had some on our old 6-inch rail that broke, but we thought that was due to the kind of rail.

MR. SCULL: Are you paying the Falk Company a royalty?

MR. BOWEN: Yes; we have thirty-two thousand joints in, and pay so much royalty for each joint.

MR. LITTELL: On the street that this particular rail parted in two we have four curves. At two points on this street the special work pulled apart at the curve, and in one instance the joint of the rail only separated; the rail pulled apart at the joint. On examining this joint we found that the trackmen had slighted it. They had relaid the track, and when they connected up that joint they put in some small bolts, so as to connect it up, and when they put in the new rail they left in some ¾-inch bolts instead of using 1-inch bolts. It could not be drawn up tight.

MR. HEFT: Why use a copper bond with a cast welded joint; is it done as a precautionary measure?

MR. BOWEN: I did not know just what to do. We cut off probably ten or fifteen joints, just taken at random along the track, and out of that number I found several in which we failed to have any amalgamation in these little spots I have described with the rail. I will say that that was in the first part of our work, probably a year ago. Then to prevent tearing up a granite pavement afterward to bond, which we were putting down on that line of road, I thought it was cheaper to bond, and be sure, than not to bond and be sorry. I am waiting now for the development of that matter. I think Mr. McCulloch has made some researches in that direction, and I am down here principally to hear from him on that subject.

MR. HEFT: Then you do not feel safe in the present state of the art without using the copper bond?

MR. BOWEN: That is my position.

MR. DODGE: About that polishing up of the side of the rail, you were particular in getting the surface bright?

MR. BOWEN: Not so bright, as we were using the joint with a bond.

MR. DODGE: The Falk Manufacturing Company, which has been doing the work in New Haven, polished the joints by an electric motor, and the motor gave out, so that they could not use it. I was looking over their work and saw a man polishing the joints with a file. I asked him if it was not necessary to have it brighter, and he said: "That is just as good." They were using it without a bond.

MR. BOWEN: Then they will burn some coal. (Laughter.)

MR. DODGE: It struck me that way.

On motion the meeting adjourned until 9 o'clock Wednesday morning.

WEDNESDAY'S SESSION.

President Littell called the meeting to order and announced the first business to be the reading of the paper on "Trucks," by Mr. John N. Akarman, superintendent of the Worcester Consolidated Street Railway Company, Worcester, Mass., who was unable to be present.

Secretary Pennington read the paper.

Vice-President McCulloch took the chair. The paper on "The Modern Power House" was then read by Mr. Richard McCulloch, civil and electrical engineer, Citizens' Cass Avenue and St. Louis Railways, St. Louis, Mo.

MR. ROSSITER asked if any of the members had had occasion to use the storage battery, and if so, with what success.

MR. RICHARD McCULLOCH: There is one installed somewhere in Pennsylvania, and the Union Traction Company, of Philadelphia, have one installed at the end of one of the long lines for the purpose of regulating the voltage at that point, but there is a storage battery in operation in parallel with the dynamos, I think, at Easton, Pa.

MR. B. J. ARNOLD: During the last year I have had installed in the Chicago Board of Trade plant, as the consulting engineer for that corporation, a battery auxiliary. In my opinion the work of the plant is more severe, if anything, than electric railroad work, because it operates electric elevators in conjunction with constant potential arc and incandescent lights. The elevators take a startling current varying from 0 to 800 amperes, and back again almost instantly, corresponding in abruptness to the load on an electric railway operating three or four cars. In the Board of Trade plant the battery auxiliary acts as an equalizer and takes the surplus load delivered into the bus cars, when the demand on the line is less than the capacity of the generator, and takes three-quarters of the overload when the pull comes. The result is that with a 75 kilowatt generator, running from 7 in the morning until 11 o'clock at night at its absolutely normal economical load, it produces sufficient energy to operate fifty 2,000 candle power arc lamps, 600 incandescent lamps, four 30 horse-power electric elevators, and six 10 horse-power motors, all running from this one unit, and the unit constantly loaded. That is my experience with the battery, and it is working perfectly satisfactorily, having been running nearly a year and has cost practically nothing for repairs. We have increased the plant by putting in additional plates, because we required additional capacity, but there was no charge for repairs, and I am convinced that the battery auxiliary, when there is sufficient lead installed to do the work, is an eminent success for regulating work and economical operation of power stations operating on variable loads. I do not take this

stand without having gone into the matter pretty thoroughly, and I feel sure of my position. You must get lead enough into the battery to do the work, and having that, you will get good results, that you can rely upon and base your calculation for economical operation.

The battery was made by the Electric Storage Battery Company, Philadelphia-Manchester type of positive plate. That is another thing you gentlemen should be careful about in your investigations—the type of plate you get. It makes all the difference in the world if the plate is built for regulation or for slow discharge. This particular type is for regulation and also performs the function of slow discharge if necessary. The engines and generators stand idle from 11 o'clock at night until 7 in the morning, and the battery does the work through the night. That enables the engine to operate sixteen hours a day, with two shifts of labor, at its economical normal load, and shut down at night until morning. That can be effected in a large number of electric railway plants in this country with success. It is only a question whether the increased economy will be more than the interest on the investment of the cost of the battery. I am installing now three different stations, part railroad and part lighting, in which it is my idea to use batteries, by which I will find it necessary to put in one-third less capacity of engines and generators that would be otherwise necessary.

MR. HAWKIN: What is the life of the plate under constant use?

MR. ARNOLD: I cannot tell you; the plant has not been running very long, only about one year. It is guaranteed at 7½ per cent. per annum. On that basis I figure out a marked economy and feel that we are safe because the company behind the battery will stand up to the guarantee. As a matter of fact it has not cost 1 per cent. this year; probably it will cost something next year, and so on each year, but the battery company stands behind it.

MR. HARRINGTON: What is the construction of the two plates, the positive and the negative?

MR. ARNOLD: The negative plate is what is known as the chloride negative. It is cast lead containing square pellets of spongy lead originally peroxide of lead and reduced to spongy lead. The positive plate is a lead grid containing antimony, so as to make it hard and has round pellets, which consist of strips of corrugated lead, coiled on themselves, like a spiral, the lead being cast around it, or the spirals pulled into plate, and afterwards converted into peroxide of lead by an electrolytic process, and the plate when thus completed is called the Manchester plate. It is porous and you get a quick discharge on a heavy pull, and it does not buckle and fall out, as some battery plates have done in the past. One thing I will speak of which may interest you—that is the method of charging the battery. By running the electric elevators and the battery auxiliary in parallel with the shunt winding of the generator, and by running the lights in the building on a separate set of bus bars off the compound winding of the same generator, so that the variable load on the elevators is taken care of entirely by the shunt winding and the battery, while the compound winding works constantly on the lighting load, I get the best regulation, so that the fluctuation of the voltage is not noticeable in the building. There is a slight variation of from two to eight volts under extreme conditions, which seldom occur, but is good enough in practice, so that one unit does the work without serious fluctuation in voltage.

We use a booster in the station, which consists of a motor generator to charge the batteries, if it ever becomes necessary, while the generators are running on the lines, because then voltage must remain constant at 125 volts. Then if we wish to charge the batteries we use the auxiliary booster to charge the end or regulating cells, while the shunt winding of the generator is working in parallel with elevators and about sixty of the cells. The elevator service is such as to allow the battery to be charged and discharged in about equal proportions through the day, so that it is practically fully charged at the end of the day's run, and at night if they are slightly discharged we charge them up with the booster by placing the generator end of it in series with the main generator, and at 11 o'clock shut down the engines and run the lights until morning with the batteries. In a railroad power station it would be necessary to use the booster to increase your voltage on your long feeders. If the battery were located at the end of the line you would have to use the booster to overcome the pressure at the battery, or else run a separate high voltage generator.

MR. HARRINGTON: I understand from the experience of a large number of railway engineers that the ordinary size plant, running from 200 to 250 horse-power, where the load constantly changes, that by reason of trouble on the line the standard forms of multipolar generators flash from brush to brush, and cause a great deal of trouble in the commutators of the machine. That is a common occurrence in the Philadelphia Traction Company's plant; they suffer from that trouble there. We have had it in our own plant, with both Westinghouse and General Electric machines. The storage battery would be an excellent thing to avoid that form of breakdown or delay, due to the burning of the commutator. I would like to know if any one here has had the same experience in the stations operated by the gentlemen here.

A communication from the Engineers' Club of St. Louis was read, inviting the members to attend a meeting of that club, to be held in the evening.

The privileges of the floor were granted to Mr. Seiryo Mine, Electrical Engineer to the Japanese Government, who was present.

THE PRESIDENT: We will now proceed to the consideration of the paper, "How Can the Revenue of Street Railways Be Increased, taking into consideration the collection of fares, method of registry, transfers, use of tickets or cash fares, and attractions along the line of the road?" by Mr. C. D. Wyman, general manager of the Milwaukee Street Railway Company, Milwaukee, Wis.

Mr. Wyman read the paper.[1]

MR. SEELY: I ask the author of the paper whether he found any opposition to the issuing of this pamphlet by the trade unions of the city. You were going into the advertising business, when you solicited advertisements, and I believe there has been some objection to that by threatening a boycott.

MR. WYMAN: As far as advertising went we only had a very few advertisements, and they were from very strong firms, that I do not presume any trades' union would have any effect upon. We had, perhaps, half a dozen. The cost of the paper was very little—for the 1,500 or 1,800 copies which were issued monthly, about $15 or $20, so that it amounted to little or nothing. We had at that time a union, which has now passed away, and there was some talk about its being intended to disrupt the union. In one issue of the paper I suggested the formation of a benevolent society, and that caused a great disturbance among the men, but that did not make any difference to us. We went right on just the same, and after a while, inasmuch as the paper only covered the ground intimated, simply giving information concerning the operations of the road, and perhaps mentioning some employé of the road that did something worthy of notice, all that trouble died out. At first the union looked at it somewhat askance, and I believe advised its members not to read it, but that soon passed off, and every issue of the paper was freely taken by the men.

THE PRESIDENT here announced that cars would leave the Southern Hotel promptly at 2 o'clock for the Fair Grounds, and all in attendance at the meeting were invited to accompany the party.

THE PRESIDENT then appointed a committee to nominate officers for the ensuing year and to report upon a place for the next meeting.

The meeting then adjourned until 10 a. m. Thursday.

THURSDAY'S SESSION.

PRESIDENT LITTELL called the meeting to order at 10:40 a. m. The secretary announced that the following companies had joined the association: Street Railway Company of the Federal District of the City of Mexico; Atchison Railway, Light and Power Company, Atchison, Kan.

MR. H. H. LITTELL: I feel safe in saying that the exhibit made by the manufacturers and dealers in railway supplies at this meeting is the largest, finest and most complete that has ever been shown at any meeting of this association. I do not know of any better way to show our appreciation and to encourage the efforts put forth by our friends in the trade than to take a recess for the purpose of examining in a body their goods and wares. I move that before proceeding with any other business we take a recess until 12 o'clock to inspect the display of street railway supplies. Carried.

The meeting accordingly adjourned.

The delegates reassembled at 12 o'clock.

THE PRESIDENT announced that at 2 o'clock cars would be in waiting at the Southern Hotel to take the attendants to the Anheuser-Busch Brewery, and that the annual banquet would take place at half-past eight o'clock in the evening.

THE PRESIDENT: The first order of business is the reading of the paper on "Modern Overhead Electric Construction," by B. Willard, general superintendent New Orleans City and Lake Railroad Company, New Orleans, La.

Mr. Blake read the paper, Mr. Willard being unable to attend the meeting.

The Nominating Committee then reported the following nominations:

For president, Robert McCulloch, vice-president and general manager, Cass Avenue and Fair Grounds Railway, St. Louis, Mo.; first vice-president, Charles S. Sargeant, general

VOL. XXII. NEW YORK, OCTOBER 28, 1896. No. 443.

CONTENTS.

THE BERLINER PATENT.

THE argument before the United States Supreme Court in the suit of the United States vs. the American Bell Telephone Company, has been reassigned by the Supreme Court to November 9 at the head of the call. Our readers will remember that this suit was brought by the United States to cancel the Berliner patent, No. 463,569, owned by the Bell Company. The suit was begun in February, 1893, by the Attorney General on behalf of the United States, and reached a bearing in June, 1894, before Judge Carpenter, of the United States Circuit Court, District of Massachusetts.

Judge Carpenter adjudged in favor of the United States, and ordered the cancellation of the patent on the grounds of fraudulent delay in the Patent Office, and a previous patent to Berliner which disclosed and claimed in combination the identical apparatus claimed in the patent under suit. The Bell Company appealed from his decision to the Circuit Court of Appeals and obtained a judgment overruling Judge Carpenter's decision. The United States then appealed to the Supreme Court.

It is understood that Mr. Joseph H. Choate, of New York, and F. P. Fish, of Boston, will appear for the Bell Company, and Judge R. S. Taylor, of Fort Wayne, and Causten Browne, of Boston, will present the case for the United States, both by oral arguments and briefs. The Attorney General has also appointed as special assistant counsel for the United States ex-Solicitor General Charles H. Aldrich. It is understood that Mr. Aldrich will argue in greater detail some of the points set up by the United States for urging the cancellation of the patent. In view of the near approach to final conclusion of this celebrated case it may not be without interest to recall briefly its history.

The Berliner patent in question was applied for on June 4, 1877, by Emile Berliner, and after a delay of more than fourteen years in the Patent Office, was issued to the American Bell Telephone Company on November 17, 1891. The bearing of the patent upon the telephone business is briefly as follows: On March 7, 1876, over a year previous to Berliner's application, the government granted to Alexander Graham Bell the fundamental patent on telephony. Not only did Bell claim "the method of and apparatus for transmitting vocal or other sounds telegraphically, as herein described, by causing electrical undulations, similar in form to the vibrations of the air accompanying the said vocal or other sounds, substantially as set forth," i. e., by his magneto telephone, now and for years universally used for the receiver, but he also claimed "the method of producing undulations in a continuous voltaic circuit by gradually increasing and diminishing the resistance of the circuit . . . as set forth." This claim has been held to cover the method of all microphones. Under it the Bell Company would justly control the telephone business during the life of the patent. Just previous, however, to the expiration of this patent, the Patent Office issued to the Bell Company the Berliner patent, which had lain in the office for over fourteen years, and by which they now hope to extend their monopoly over an additional period of seventeen years, or until 1908, a total period of more than thirty-two years. The Berliner patent claims:

"The method of producing in a circuit electrical undulations similar in form to sound waves by causing the sound waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described."

The second claim is equally broad and covers the transmitter as an apparatus for thus transmitting speech. In other words, the Berliner patent apparently covers the apparatus necessary in order to utilize the invention of Bell, although such apparatus had been continuously and successfully in commercial use for thirteen or fourteen years, during which this patent lay in the Patent Office awaiting its issuance.

The American Bell Telephone Company has argued that the patent was secured under the rules of the Patent Office, and that "it was absolutely impossible for the defendants to have hastened the grant of the patent." On the other hand, the United States claims that the delay was unnecessary and amounted to bad faith on the part of the Bell Company toward the public. Among other grounds set up by the United States urging the cancellation of the patent are (1) Irregular procedure in the Patent Office outside of the uncalled-for delay, and the insertion of new material subsequent to the filing of the application. 2. The application as filed did not describe the constant-contact, variable-resistance transmitter which is the subject matter of the patent as issued, but did describe a "make and break" transmitter for the transmission of speech. The original application and drawings were twice erased and stricken out and new ones substituted containing the constant-contact device. 3. The United States claims that the invention in question was described and disclosed and claimed in combination with the identical apparatus used as a receiver in the patent of November 2, 1880, granted to Emile Berliner.

The decision of the Supreme Court will, of course, be of great importance to the public, for it is believed that the Bell Company own no other patents of sufficient scope to extend their exclusive monopoly beyond the twenty years which they have already enjoyed. Should, however, the Supreme Court uphold the validity of the patent it would appear that the public must still be deprived of most of the advantages of active competition until the year 1908.

THE ST. LOUIS STREET RAILWAY CONVENTION.

THE return to St. Louis of the American Street Railway Association, for its annual convention, after several years of absence, has been a very interesting event. It is by such a return that one is able to measure the distance that an industry has traveled. When the association met last in the great city by the Mississippi, the horse was still the motive power of American street railways, with the prospect of a long supremacy, for the cable was seen to be suited only to large cities and electricity had a few visionary advocates like ourselves, who could hardly obtain a hearing even in their own field of endeavor. To-day St. Louis is a splendid type of what can be done in supplying a great population with satisfactory travel by means of the electric motor, and electric traction is triumphant in every city of the Union—New York alone excepted. In fact, all future work is largely predicated upon electricity, except in New York again, where some people are foolish enough to dabble again in experiments with that which has ever been found a failure, for such work, namely, compressed air.

The St. Louis convention this year has been highly successful. The meeting was very well attended, the exhibit of apparatus was far beyond the average, and the papers and discussions were of an admirably useful character. It is true that a tendency to go into executive session is beginning to manifest itself, a development often associated with moribund conditions in such bodies; but the matter is one that must be settled for itself by an organization and that which speaks for street railways is certainly more vigorous and prosperous than it has been for some time past. Its wise choice for president, Mr. McCulloch, is an earnest of willingness and ability to do good work in the future, and to the support of such an administration all well wishers of the industry will rally.

While the papers and reports read before the convention were not numerous, what they lacked in quantity they made up in quality. Without exception, they treated specific subjects of the highest importance in the railway management in an intelligent and instructive manner, and furnished a good basis for the discussions which ensued. Some of the reports being left entirely to individuals, they may, of course, reflect to a large extent the individual opinions of their writers, but in general their contents are of distinct general application. As to the best methods of increasing the revenue of a road, which formed the subject of one of these reports, besides the more general observations which would suggest themselves to most intelligent managers, we note particularly the results of the attempts made to increase receipts by the inauguration of pleasure resorts on the line of railroads. Such resorts, it would seem, have not been uniformly successful, and, indeed, but few have come up to the expectations of the companies which added them as passenger feeders to their roads. But while experience would indicate that railroad companies are not successful show managers, or caterers to public amusement, there is no reason, as pointed out, why these adjuncts should not be encouraged, but their management left in the hands of independent parties who have made the business their own particular study. We believe that this suggestion will be followed in the future, thus leaving the railroad company to the exploiting of its own legitimate business, the carrying of passengers. The question of transfers was also very properly dwelt upon in the report. We believe that experience has fully demonstrated the wisdom of a liberal transfer system, and we know of no better way by which a steady, paying passenger traffic from and to suburbs can be built up. After all, it is the men of moderate and small incomes to whom the street railway companies must look for a large percentage of their income, and anything that can encourage this class of passengers to avail themselves of the facilities offered must lead to an increase in the receipts.

The question of the advisability of reducing the standard rate of fare now existing elicited the information that there is no more profit in urban electric railways than there was in the old days of the horse. There is, in fact, less in proportion to the business handled. This might look like an arraignment of the electric railway, but to those who know the greatly increased and exacting demands of the public in the way of conveniences since the electric car entered the field, the information will not be a particularly startling piece of news. For the present, therefore, we believe that no reduction in fares is possible if roads are to be run and maintained at their highest efficiency, but there may be hope for the future when the experience which time brings with it will have shown the mistakes of the past, and these have all been paid for out of earnings, as they must always be.

(Continued from page 429.)

manager, West End Street Railway Company, Boston, Mass.; second vice-president, D. B. Dyer, president, Augusta Railway Company, Augusta, Ga.; third vice-president, C. F. Holmes, general manager, Metropolitan Street Railway Company, Kansas City, Mo.; Executive Committee, H. M. Littell, vice-president and general manager, Metropolitan Street Railway Company, New York City; H. P. Bradford, general manager, Cincinnati Inclined Plane Railway Company, Cincinnati, O.; Chas. H. Smith, superintendent, Troy City Railway Company, Troy, N. Y.; Harry Scullin, vice-president and general manager, Union Depot Railway Company, St. Louis, Mo.; George B. Hippee, general manager, Des Moines City Railway Company, Des Moines, Ia.; for secretary and treasurer, Thomas C. Penington, treasurer, Chicago City Railway Company, Chicago, Ill.

The report was accepted and the secretary instructed to cast the ballot of the association for the gentlemen nominated.

Calls for Mr. McCulloch.

MR. ROBERT McCULLOCH: I will only say that if I had constituted the entire nominating committee, or been the returning board, or if I had carried the electoral vote in my pocket, you would have had a different standard-bearer for the ensuing year, and for fear you may think I am not appreciative, I will not criticise your action. I thank you for the personal compliment you have paid me, and the courtesy you have extended to the city of St. Louis; and all I promise you is that while I sit on the executive throne of the association, your banner shall not be trailed in the mire. (Applause.)

The Nominating Committee also designated for the next place of meeting, Niagara Falls. (Applause.)

MR. LANG stated that some of the material men had said that they thought there might be a lack of facilities for getting their heavy machinery and cars in and out. He was assured that it will be most convenient to get cars and the machinery in and out owing to connections to be made not only with the street railways, but also with the steam roads.

MR. SEELY offered the following resolution:

"Whereas, Suggestions and propositions have been made looking to the consolidation in one body of the American Street Railway Association and the National Electrical Light Association,

"Resolved, That in the opinion of the American Street Railway Association such union is not called for." (Applause.)

The resolution was adopted.

The secretary read the following letter:

To the American Street Railway Association:

Gentlemen—I would respectfully ask that a committee of five be appointed to consider the propriety of this association adopting a standard code of rules and regulations for the government of employés, something similar to the practice of steam roads.

I fully appreciate the objections which this will meet with, but believe it is in the line of advancement, and any road can adopt the rules in their entirety or in part. Local conditions would make it necessary for changes in a large number of the rules that would probably be adopted, but in the main the instructions to conductors and motormen about reporting, conduct, etc., would apply to all. It would be valuable to have this class of employés educated, so that their principal duties would be the same on all roads. Owing to the opening of a new line it is necessary for me to leave here at noon to-day, which is my reason for addressing this to the convention in writing.

IRA A. McCORMACK,
Gen'l Supt. Brooklyn Heights, R. R. Co.

MR. H. H. LITTELL: I move that the suggestion of Mr. McCormack be carried out and the committee appointed. Carried.

The meeting adjourned until 10 o'clock Friday morning.

FRIDAY'S SESSION.

PRESIDENT LITTELL called the meeting to order and announced the first business to be the reading of the paper on "The Selection and Management of Employés," by Mr. W. F. Kelly, general manager of the Columbus Street Railway Company, Columbus, Ohio.

The Secretary read the paper.

MR. SCULLIN: I would say that in connection with that part of the paper which relates to the furnishing of reading rooms, lavatories and sort of reception room for the men, our road took that step about a year ago, when we were building a new shed. We put in a nice waiting room for them, with a library containing a few standard works, and subscribed for some of the magazines. We also put in a gymnasium for them; not an expensive one, but provided with a punching bag, lifting machines, etc. In this way we can always find the men. When we want an extra man he is on hand, as there are always a number of them reading or exercising in the waiting room. We also provided a bathroom, with a shower bath, and in every shed we are now putting in these rooms. It is a splendid move and the men appreciate it; but, as Mr. Kelly says, it is not an act of charity—it is a duty we owe to our men. The street railway men will never regret having taken this matter up. In relation to taking a man off and making him lose a great deal of time, while I am rather a young man, at the same time I have given considerable thought to the subject. If you take the man off you take part of his livelihood away from him, and he is going to get it if he can. A better practice is to reprimand a man, not take him off; reprimand him once or twice; show him that you mean what you say, and the second or third time let him go.

MR. ROBERT McCULLOCH: We have three or four different gathering places for our men, and we have three rooms at each of three different places which we have equipped very nicely for the comfort and convenience of the men. One of them in particular is eighty feet square; it is heated by steam and lighted by electricity. The men have built a very nice stage and have organized amongst themselves, among other things, a sort of Thespian corps, and they give remarkably good performances of a theatrical character from talent among themselves. They have a piano and a dancing master who comes there, and they have dancing classes and bring their wives and daughters to them, and our hall is much in demand for the giving of entertainments by church organizations in the neighborhood. We give it to them free. The hall has done a great deal of good to keep the men out of saloons and to furnish them a place where they may have any kind of gatherings which they may desire. We exercise a control over their organization by having some of our officials as members of it, and prohibit any discussions relating to the affairs of the company or the relations of the men to the company. They may debate any questions they choose of a general nature. We allow no liquor to be served there in connection with their entertainments or with those that are given by others. We have kept the character of the place respectable and it has been running now about six years, and it has done a great deal of good. A great many of our men do not appreciate these things, but we don't feel that we have wasted any money.

MR. MAHONEY: I would like to get the views of some of the gentlemen present as to the custom of charging the employés with trivial accidents, breaking wagons, etc., whether they are to blame in the matter or not.

MR. H. H. LITTELL: The question of making a motorman pay for damages to a vehicle, etc., is probably a very serious one. On our system in Buffalo we sometimes make them pay a portion of the cost when we are convinced that it was the carelessness of the motorman that caused the accident, but in a great many cases, if, after investigation, we find he is not to blame, we pass it over. I think if they are careless and break a vehicle or injure a car, and you charge them with it, it is not so liable to occur again; but if a man continues to have accidents of that nature, it is a good thing to dispense with him before something serious happens. When we discharge a motorman for breaking a wagon or causing an injury to the car we do not deduct anything from his pay. In regard to rooms, I think that all well regulated street railway companies should have closets for their motormen and conductors; some place where they can hang up their rubber coats and put in their overshoes and heavy gloves, where they can change their clothing, if they desire, and these closets or wardrobes should be thoroughly ventilated. I think it is positively necessary to have a good place where the men can congregate and read, play a game of cards, so long as they do not play for money, smoke and have chess and checkers and any amusement that will keep them at the proper reporting place. We have nine such places. We have lavatories at all of our buildings and all the necessary conveniences.

MR. MUSSER inquired if Mr. McCulloch passed his employés free to and from his place of amusement at all times.

MR. McCULLOCH: Our employés ride free on their badges at all times.

MR. BENDURE: I find it a good plan to retain some of the wages of the employés to cover these minor accidents. Before I did that there was trouble all the time with the men getting too near buggy wheels. I made it a rule to retain $15 from each motorman and $10 from each conductor to cover damages to the property of the railway public, if they were to blame, and damages to trolleys under overhead switches. I have had the rule in practice now for ten months, and I have not had to deduct a dollar for these damages. They have almost entirely ceased. We run six cars, and in my brief experience I find it a good thing to do.

MR. LANG: We make it a practice to require the men to meet the expenses of accidents occasioned by their gross carelessness. If there is any doubt in the matter we decide it in favor of the employés.

MR. McCULLOCH: The question of fining a man or making him pay for damages is a very serious thing. We have not done that. If I think a man ought to pay for a damage or deserves punishment, I discharge him. We have in many instances offered a gripman or motorman the alternative of paying for a damage or giving up his place. That would be where a man had several small accidents. In some instances they have declined to pay and have given up their places; in others they have accepted the condition, paid the damage and retained their places, and we have very seldom had another accident from that same man. We have never both discharged a man and made him pay for a damage.

MR. H. M. LITTELL : In the company I am connected with all reports regarding accidents, dismissals and suspensions are put on the blackboard. When a man has been reported four or five times he is then warned. We have a book in which we make the entry of the date of a man's employment, and any record in regard to his references is kept in another book, every time a report comes in against him it is entered in this book, it does not make any difference what it is. When there are eight or ten reports against him the book is then handed to the superintendent, who calls the man, reprimands him, and enters in red ink "warned," with the date. Another eight or ten will come along and he is warned again. Probably that man's page will be filled up before he is warned three or four times, and then he is discharged. When he is discharged we never re-engage him.

As to accidents on our cable and electric roads, when a man has an accident he reports it at the end of the trip. He walks into the station and dictates the report to a stenographer. When he gets back on the next trip the report is written out and he signs it. He does not lose any time. This report is then sent to our claim department, and if the claim agent thinks it necessary to talk with this man he sends for him; he is called to the office. When he leaves the station the foreman gives him a card, for instance, "John Smith left the station at 9:10 a. m." He goes to our claim department, recites his case and the claim agent then indorses on this card, "Retained until 3:10 p. m.," or whatever time he was kept at the office. This goes back to the division superintendent and he O. K.'s it. If the man has been five hours away he is paid for it; if he loses one hour he is paid for it; if he loses a day he is paid for it. In that way we believe we get our men to report all accidents, even the most trivial incidents. It is the small accidents which give us the most trouble—accidents which, in the mind of the conductor, or gripman, or motorman, he would think, "Well, that is not worth reporting," and he says nothing about it. But the railroad company may hear of it in a month or two, or possibly a year or two, and these are the most difficult cases we have to defend, because we have no report and no witnesses. The conductor has gone or the gripman has disappeared. We talk to our men and try to impress upon them the importance of reporting everything. It does not make any difference if a man stubs his toe on the car, we want a report of it if the conductor knows about it. If a man falls off a bicycle alongside the track and there is a car approaching, we want a report. If a man stubs his toe on the street crossing and falls while a car is passing we want a report of that. With regard to rules, we have rules, but we believe we can do more with our men by getting them together and talking to them. Our gripmen and conductors have a club, called the Metropolitan Club, with such a large membership now that we are compelled to increase the size of their quarters. We finished a few days before I left home a room 120 feet long by 80 feet wide. They have a stage and piano, and the room is well lighted. We have in this room controllers, grips and other appliances; we have miniature cars and tracks, with the conduits exposed; we have broken grips. If a man should have an accident with the cable or the cable brakes we bring in the piece and show it to the men, and then tell them how to overcome it. We believe we we can do more by talking to them than by trying to reach them through a book. They have their toilet rooms, etc. We do not put them together. We have a conductors' room, a drivers' room, a gripmen's room and a motormen's room. They do not associate together at all. You will rarely see a conductor in the motormen's room, or a motorman in the conductors' room. They have their own lockers in the separate rooms, and have checker boards, tables, chairs and all that kind of thing.

About discharging men, I have a report come to the office every week, giving the number of men discharged on each division, and if I find that the division superintendents are discharging too many men I send to the stations and get the records of the men and find out the reasons. I am quite positive that there have been a great many men discharged unjustly for no good reason. Our foremen are as liable to make errors as the men are to make them. If a man is discharged we require that his complete record be sent to the main office. Sometimes it takes a sheet of paper, typewritten, a yard long. It makes our foremen careful, and they are not going to discharge a man for some trivial offense. We do not like to change our men. If a man does something which is not exactly right we talk to him, and we try to make it pleasant for him and keep him in our employ. The men are paid more wages the second year than they are the first. We believe that is some inducement for the men to stay with us.

MR. H. H. LITTELL: Our road is not as large as the one represented by the president, but we make a record of every complaint that comes in against either a conductor or a motorman, but we do not wait until there are four or five complaints against him; we call him down on every complaint, either by sending for him when he is off duty, so that he shall not lose any time, or sending a man to him to call his attention to what he is reported as doing, which is in violation of our rules, or which, in our opinion, is a violation of good judgment. I think it is due to the man that he should be told, if it is possible to do so, every time that he is reported. We punish our men a little differently, I think, from the methods pursued on most roads. I find if you have a man who has been on the road for some months and he gets a little careless it is a very excellent punishment to put him for one or two days on some other route, with some old motorman or conductor, as the case may be, and let him practice—"sub it," as we call it. It is the most effective punishment we have yet introduced. We apply this remedy for slight offenses, such as omitting to announce streets, failing to keep the platforms clear when it can be done, etc.

There was some further discussion on the subject of transfers, children's fares, and methods of checking conductors' collection of fares, but being in executive session, the matter was not issued for publication.

The meeting then passed a vote of thanks to the various bodies and individuals that had helped to make the convention a success.

THE PRESIDENT appointed as the Committee on Rules for Conductors and Motormen Messrs. W. F. Kelly, Columbus, Ohio; M. K. Bowen, Chicago, Ill.; E. C. Foster, Lynn, Mass.; Ira A. McCormack, Brooklyn, N. Y.; H. H. Vreeland, New York City.

Mr. McCulloch, the president-elect, was then escorted to the chair and made a brief address.

MR. DAVIS offered the following: "Resolved, That the secretary be instructed to obtain from the members of the association information and copies of municipal legislation relating to the imposition by their cities or municipalities of taxes or license fees upon the companies' property, franchises or receipts."

The foregoing was referred to the executive committee.

The meeting then adjourned, to meet at Niagara Falls on the third Tuesday in October, 1897.

CONVENTION NOTES.

THE ANHEUSER-BUSCH Brewery was the scene of the junket on Thursday afternoon, the party traveling on the Union Depot and Southern Electric cars.

A THEATER PARTY of about 150 enjoyed "In Gay New York" on Wednesday evening, when that giddy play had been besprinkled with gags for their special delectation.

COL. N. H. HEFT, president of the Meriden, Conn., Street Railway Company, has the distinction of being the first steam railroad man to become a member of the association. As a representative of the Consolidated System in New England he was asked innumerable questions as to the work at Nantasket Beach.

A TALLY-HO PARTY.—In honor of Captain Willard L. Candee, Mr. Pierre C. Gurneau made up a tally-ho party for the races. Captain Candee is considered one of the best whips in the East, and the manner in which he handled the ribbons amply justified his reputation. The party also included President Littell, of the association, Messrs. Brill, Price, McQuaide and others.

VISIT TO A NEWSPAPER OFFICE.—A number of the members who did not participate in the trolley car ride and entertainment at Forest Park on Tuesday afternoon, visited points of interest in the city. President Littell headed a party of some thirty gentlemen who wished to see a complete newspaper plant. They were shown through the "Globe-Democrat" building, and in spite of their thorough acquaintance with mechanical appliances marveled much at the wonders of a large newspaper office.

THE ATTENDANCE OF ACTIVE STREET RAILWAY MEN was not so large as hoped for, but there were no fewer than eighty different cities represented, and the personnel was of a very high order. The membership includes, as is well known, a great many men who are also actively interested in

supplies, and who may, therefore, be said to attend the convention in a dual capacity. The attendance and participation of the ladies was very gratifying, no fewer than 125 taking part in the excurisons and festivities. Of this number about half were visitors to the city.

A SPECIAL CAR RIDE.—On Tuesday afternoon at 2 o'clock the members of the association, with their wives, boarded the cars at Seventh street and rode to Washington avenue. There they found the special car "Rover" and three other nicely decorated cars of the Lindell line awaiting them. The party was transferred to the Lindell cars and taken to Forest Park. Arriving at the Lindell pavilion the party was served with light refreshments while a band played. After the refreshments the tables were cleared away, and dancing was indulged in. At 4 o'clock the party was driven through the park, Westmoreland and Portland places, and thence back to the Southern Hotel.

THE BANQUET.—The annual banquet on Thursday night was a grand success. Three hundred persons were present. The cuisine and floral decorations were all that could be desired, a superb orchestra discoursed music during the service of the dinner, and in some of the more familiar refrains the company joined in singing. About fifty ladies graced the occasion. The speeches, of which the following is a list, were exceedingly good: "City of St. Louis," Hon. Charles Nagel; "Welcome to Our Guests," Mr. F. N. Judson; "The Street Railway in the Courts," Mr. Smith P. Galt; "The Street Railway as a Social Factor," Mr. P. W. Lehmann; "The Press," Mr. W. M. Reedy; "The Technical Press," Mr. E. E. Higgins. Mr. J. H. Stedman acted as toastmaster.

THE JOCKEY CLUB was visited on Wednesday afternoon, when some good racing was enjoyed by a large crowd, and the visitors were singularly successful in their betting—probably because they had had no chance to get "sure tips." The road traveled over was the Citizens'. Over 300 male and female guests were carried on the other cars. Superintendent Whalen, of the road, was in responsible charge; Captain Robert McCulloch, general manager; Secretary C. N. Duffy and Engineer R. McCulloch being also on hand. These, combined with the regular entertainment committee, did everything in their power to add to the comfort and enjoyment of the guests. After refreshments at the Floral Hall in the Fair Grounds, the adjournment was taken, as described, to the races.

THE RECEPTION.—On Tuesday evening the local entertainment committee, consisting of Harry Scullin, George Rosenthal, Arthur Partridge, Joseph Franklin, Jr., John Whittemore and Scott Blewett, was in charge of the reception tendered to the visitors at the Southern Hotel. The ladies' ordinary and four large parlors were beautifully decorated with smilax, palms, roses and chrysanthemums. At 8:30 the doors of the small dining room adjoining the ladies' ordinary were thrown open, and a buffet lunch was served throughout the evening. The dining room was handsomely decorated and the shaded light from a myriad of incandescent globes shone upon tables banked with flowers, to which 125 guests sat down. Just outside the dining room and to the east of the open court, a mandolin orchestra of twelve pieces, concealed behind a bank of palms, discoursed music throughout the evening.

MR. JOHN G. BRILL in an interview with regard to the convention and exhibits said: "The supply men have made a special effort this year to make an excellent showing. It may be a surprise to many, but nevertheless it cost in the neighborhodd of $100,000 to bring these exhibits to St. Louis and put them in their present places. Of this amount the supply men expect to realize about $60,000 from special orders and the advertising resulting. That leaves at least $40,000 with the city of St. Louis, the association and the railroad companies. These figures are not at all exaggerated. My company alone is at an expense of $10,000, and it can be seen from the other displays how easy it is to run the amount up to $100,000. We have not only paid for floor space, but have established headquarters in the largest hotels and spent large sums in entertainment." Mr. Brill added that the St. Louis exhibit far surpasses any that the association has had in previous years.

EXHIBIT NOTES.

THE display of apparatus and supplies at the annual meeting of the American Street Railway Association always requires abundant space, from the very nature of the goods, and hence a large hall or floor area is necessary. This was found in St. Louis in the big, ramshackle barn of a building built and used for the Republican National Convention in June. It was most inconvenient as to location, being several blocks away from the hotel headquarters at the Southern, and was also very damp and breezy. To provide a meeting room a large space was boarded off in one corner, from which the noise outside was but poorly excluded. The main floor was not only well filled with cars, trucks, motors, etc., but the exhibits ran up the sides under the galleries. Current was furnished from an adjoining trolley circuit at 500 volts, and the building was well lit by a large number of arcs in the ceiling. The danger of fire was great; indeed, one incipient blaze is understood to have broken out, while owing to the broken condition of the floor the risk to limb was more than once demonstrated. However, with so large a display to be assembled and broken up again in so brief a space of time, probably the best was done that was possible. As there was plenty of bunting, the scene was bright, but the attendance outside those directly interested was quite small. One or two of the bulkier exhibits were left outside the building. Altogether, the show was far better than at Atlanta or Montreal, and reflected great credit on the taste and enterprise of the participants. Music was furnished by an excellent band, to which assistance was rendered by whistles and gongs in various exhibits. The attendance of members and supply men reached about 1,000.

BERRY BROS., of Detroit, showed a full line of varnishes suitable for varnishing car bodies.

EVANS & HOWARD, St. Louis, had a line of fire brick and earthenware goods, which included boiler tiles, flue pipes and stone sinks for power stations.

THE SIEMENS & HALSKE ELECTRIC CO., of America, were represented by Messrs. C. E. Yerkes and C. D. Shain.

J. A. McGRATH had a model of a flat car equipped with his patent brake. This model was placed on a short inclined railway and loaded with heavy weights.

STERLING SUPPLY AND MANUFACTURING COMPANY, New York, showed their well-known registers and brakes. Mr. J. J. Kennelly looked out for their interests.

THE DEVLIN STEEL CAR BRAKE COMPANY, Memphis, Tenn., showed a model of their power and safety chain brake. They also exhibited a new trolley wheel in three sections.

THE BENEDICT & BURNHAM MANUFACTURING CO., of Waterbury, Conn., were represented by Mr. E. H. Oswald, who had samples with him of trolley feeder wires and solid one-piece rail bonds.

THE H. B. CAMP COMPANY, Aultman, Ohio, had on view specimens of their vitrified clay conduit, suitable for telephone, telegraph, street railway, lighting and power purposes. Mr. A. L. Daniels was in charge.

MR. EDWARD P. SHARP, of Buffalo, was in attendance at the convention, and had a list of bargains in second-hand apparatus at very attractive prices to offer to any one interested in procuring electrical apparatus cheap.

THE SECURITY BANK NOTE COMPANY, Philadelphia, had a complete line of engraving work which included a large variety of street car tickets, street railway bond forms and passes. Mr. G. S. Hall represented this company.

THE SAFFORD & MOORE RAILWAY JACK COMPANY, Chicago, showed some of their rapid tripping track and car jacks. Mr. M. M. Moore, vice-president, and Mr. N. K. Williams, secretary and treasurer, looked after the interests of the company.

THE ELECTRIC INSULATING COMPANY, of St. Louis, represented by S. J. Stein and L. Honig, showed samples of their "Peerless Armature" compound, suitable for armatures and fields, for painting switchboards, poles, conduits, lamp hoods, etc.

MR. GEORGE F. REARSEN, manager of the National Jack Company, Boston, was around showing his device, and judging from the number of those who called at his interesting exhibit it is very probable that they will be used on many more street railways before long.

LESCHEN-MACOMBER-WHYTE COMPANY, of Chicago, showed samples of iron, steel and copper wire, wire rope, black manilla transmission rope, galvanized span wire and overhead line material. They were represented by Messrs. F. B. Macomber and George S. Whyte.

THE FITZGERALD VAN DORN CO., of Chicago, showed two of their No. 5 couplers on two small flat cars, two of their No. 7 couplers, and also the No. 4 coupler, which is used on the Metropolitan Elevated Railway, Chicago. Mr. W. T. Van Dorn had charge of the exhibit.

THE CREAGHEAD ENGINEERING COMPANY, of Cincinnati, were represented by G. R. Scrugham. They showed the Creaghead flexible brackets, overhead line material, malleable iron cross arms, a full line of fittings for iron poles, and the Manhattan arc lamps. These were shown burning five in

series on a street railway circuit, and were of the well known inclosed arc type.

MR. EZRA H. LINLEY, of St. Louis, had a well filled booth, with specialties of the following companies: William Joseph & Sons, Nathan Manufacturing Company, Midvale Steel Company, Morris, Tasker & Co., Detroit Steel and Spring Company, Cambria Iron Company and other leading manufacturers of engineering specialties.

THE ADAMS AND WESTLAKE COMPANY, of Chicago, were represented by H. E. Keeler, W. S. Bartholomew, F. B. Jones and L. A. Gray. They showed samples of their Acme curtains for closed and open cars, gravity ratchet brake handles, arc lamps, and a general line of car trimmings, headlights, chandeliers and everything connected with car equipment.

WOODS' PATENT CAR GATE was shown by Mr. C. Kinne, who represented the R. Bliss Manufacturing Company, Pawtucket, R. I., who are the sole makers. This gate is very simple in construction, and when opened full or closed it is kept securely in place by means of a double acting spring lock. These gates are used on quite a large number of street railroad cars throughout the country.

THE FOREST CITY ELECTRIC WORKS, of Cleveland, O., were represented by Messrs. Cleveland and Dolph, who had an admirable display of their copper specialties. There was an enormous demand for their handsome embossed portrait of Mr. McKinley, stamped in copper and gold, and bearing appropriate legends as to the golden protection afforded by copper bonds of the Forest City make.

THE NATIONAL CARBON CO., Cleveland, Ohio, had a handsome exhibit, in which they showed a full line of the different styles of carbons manufactured by this company, amongst which they included a large assortment of brush carbons, planed down to exact dimension. They had also a fine line of carbons for telephones, which were very tastefully arranged. Mr. M. M. Hayden and R. P. O'Connor received the visitors to this exhibit.

THE KINZER & JONES MANUFACTURING COMPANY, of Pittsburg, Pa., had some sets of their different makes of brake shoes, suitable for steam and street railways. This company claim that by using these shoes with the connections commonly known as heads or hangers it is impossible "to lock the wheels," thus preventing the wheels from skidding, sliding or wearing flat. A neat model of a Wagner composition filled shoe was presented to visitors as a souvenir.

W. H. COE MANUFACTURING COMPANY, Providence, R. I., showed their gilding wheel. This machine is very simple, the gold or silver leaf being put up in different widths, like ribbon, with paper backing, in the upper flange wheel of the machine and connected with a lower belt, which is slowly rolled over the surface to be gilded. The leaf leaves the paper and adheres to the sizing. These wheels are used by several of the prominent street car companies. Mr. W. H. Coe had charge of the exhibit.

JEWELL BELTING COMPANY, of Hartford, were represented at the convention by C. L. Newton, secretary; A. E. Silk, general traveling agent, and W. G. Wheelock, Western agent. They showed a handsome sample of their celebrated belts for transmission of power, the exhibit being in charge of Mr. Silk, who represents the Jewell interests throughout the entire country, and is thoroughly capable of earning the entire confidence reposed in him by the company. Mr. Newton had some amusing experiences to relate in regard to elephant and rhinoceros hide.

J. M. ATKINSON & CO., showed a full line of their horseshoe flexible rail bonds, which are already well known. They also exhibited the Waterman rail drill, which is suitable for steam and street railways. This drill is easy to work, as it is geared so as to operate by turning one way only, and is held in place on the rail by two clamps, which can be collapsed when trains pass without taking the drill tool out of the rail in which the hole is being bored. This company also distributed a small X-ray souvenir, for which there was considerable demand. Messrs. J. M. and F. Atkinson were in charge of the exhibit.

THE OHIO BRASS COMPANY, of Mansfield, O., had a handsome exhibit of pyramidal form, in which were displayed samples of their line material, consisting of hanger bodies in a great variety of forms, eight different styles of trolley ears, complete line of material for hanging figure 8 trolley wire, and all forms of section insulators and cross-overs, steam insulators, rail bonds, feeder wire insulators, feeder wire splicers, flexible pole brackets and everything pertaining to overhead line construction. They also showed their adjustable track brush holders and brushes. A few samples of their pure bell metal bearings were also shown and the whole made a very complete and attractive exhibit. The company was represented by Mr. C. K. King, secretary, and A. L. Wilkinson, special agent.

THE CONSOLIDATED ELECTRIC PURIFIER CO., Chicago, exhibited one of their automatic electric feed water purifiers. It consists of a cylinder with a series of electro positive and electro negative plates, through which there is a water passage, the feed water passing through and over the plates, separating the various deleterious ingredients, while their affinity for the iron of the boiler is destroyed, as no one ingredient can form scale by itself. It delivers to the boiler a non-scaling water. This being accomplished, the old scale, if any, on the boiler will, from the action of the water, rot, and with the expansion and contraction of the boiler iron gradually drop off, the work being done entirely without the aid of purges or compounds of any kind. Mr. C. E. Whitmore, the president and general manager, explained the working of the purifier to the numerous callers to his exhibit.

A COMBINATION EXHIBIT.—The combined exhibit of the Lombard Hydraulic Brake Company, the Steel Motor Company and the Dupont truck attracted the attention of the delegates. The brake principle involved is the same as in the Lombard water wheel governor, and is the invention of the same man, Mr. Nathaniel Lombard. The fact that oil is the medium used to operate the brake and covers all working parts renders the work of maintaining the pressure extremely simple. The amount of oil used can be so nicely controlled by the patented device for closing the valves attached to the brake piston that the motorman can apply as much power as is required to stop the car easily or very suddenly. The company have made improvements in the method of supporting and driving the pump and connecting the same with the brake piston, pressure and exhaust tanks. They now attach the pump just as a motor is hung upon the axle, and drive it by gears. They had also a separate motor-driven pump, which can be had if desired. Mr. Daggett was in charge of the exhibit.

THE GENERAL ELECTRIC COMPANY was represented at the St. Louis Convention by an exhibit which embraced the newest developments in the electric traction field. The space occupied was the most extensive in the hall and was located immediately to the left of the entrance. The exhibit comprised examples of the standard apparatus of the company's manufacture, as well as the latest devices developed since the last convention, and Street Railway delegates and visitors found that every item had a special interest to them and to their work.

A G. E. 1,000 motor equipment was mounted on a truck and was shown in operation with the electric brake. One of the Brooklyn Bridge car trucks was exhibited equipped with two G. E. 2,000 motors and near by examples of the G. E. 800, 1,000, 1,200 and G. E. 51 types of motors. The controller section included examples of the K 10, B 6 and L 2 controllers, as well as one of those used to handle the great 96-ton electric locomotives of the Baltimore & Ohio Railroad. A switchboard made up of generator and feeder panels with full equipment of standard instruments, rheostats, etc., was also installed. Lightning arresters were shown in operation, and the magnetic blow-out device and the operating principle fully explained.

A G. E. 1,000 armature with one-half of the coils in place showed the method followed by the General Electric Company in the construction of its railway motor armatures. An electric brake adapted to trailer use, with shoe and disc, served to explain the electric brake and its principle.

The branch of electric railway supplies was represented by a series of ten Thomson railway arc lamps in operation, as well as some fine examples of the long burning type of lamp adapted to street railway use; assembled commutators of G. E. 800, G. E. 1,000 and G. E. 2,000 motors, bound solid for shipment, were also shown in connection with samples of the new frogs and overhead switches and trolleys. K and L types of circuit breakers, and the new M automatic circuit breaker for street railway car equipments, and a fine exhibit board of punched clip switches completed the display of the supplies.

The work of the company in the steam railroad field comprised a sample section of the third rail in use on main line of the New York, New Haven & Hartford R. R., a direct connected air-pump with automatic governor used on the cars operating on the same railroad, and a section of the overhead contact device used in the Baltimore & Ohio R. R. work.

The exhibition space was illuminated by miniature incandescent lamps and decorative signs.

The headquarters of the General Electric Railway Company were located in the two parlors in front of the dining hall of the Southern Hotel. The company was represented by members of their staff from New York, Schenectady, Boston, Philadelphia, Chicago, Cincinnati and St. Louis, under Mr. W. J. Clark, and numbering over twenty.

THE MEAKER MANUFACTURING COMPANY, Chicago, had an exhibit of portable and stationary street car registers, and also a line of overhead material. The exhibit was taken care of by Mr. J. W. Meaker.

KROTZ, ALLEN & KELLY, Springfield, Ohio, distributed a very neat souvenir, which consisted of four small pieces of cardboard, fastened together with red ribbon, on which were shown views taken last winter of the K. A. K. system of underground conduit made by this concern.

THE CONSOLIDATED CAR HEATING COMPANY, Albany, N. Y., had a new line of their well-known electric car heaters and temperature regulating switches. They also showed some of the smaller heaters in place under Scarritt cross car seats, the whole making a very neat exhibit.

THE ST. LOUIS REGISTER COMPANY had on exhibition some of their security registers of different grades. Amongst those shown were two with mechanism exposed to view, and the visitors to the exhibit were able to see for themselves the way in which the correct number of fares on each street car trip can be kept count of.

THE AMERICAN STEEL FOUNDRY COMPANY, St. Louis, had on view some specimens of basic steel truck frames, basic steel castings, drawn out under hammer, straight and twisted, also a basic cast steel bolster. This exhibit was located in the gallery, the castings reposing on a large cover with blue and red stars, and large and small red, white and blue stripes, the national colors.

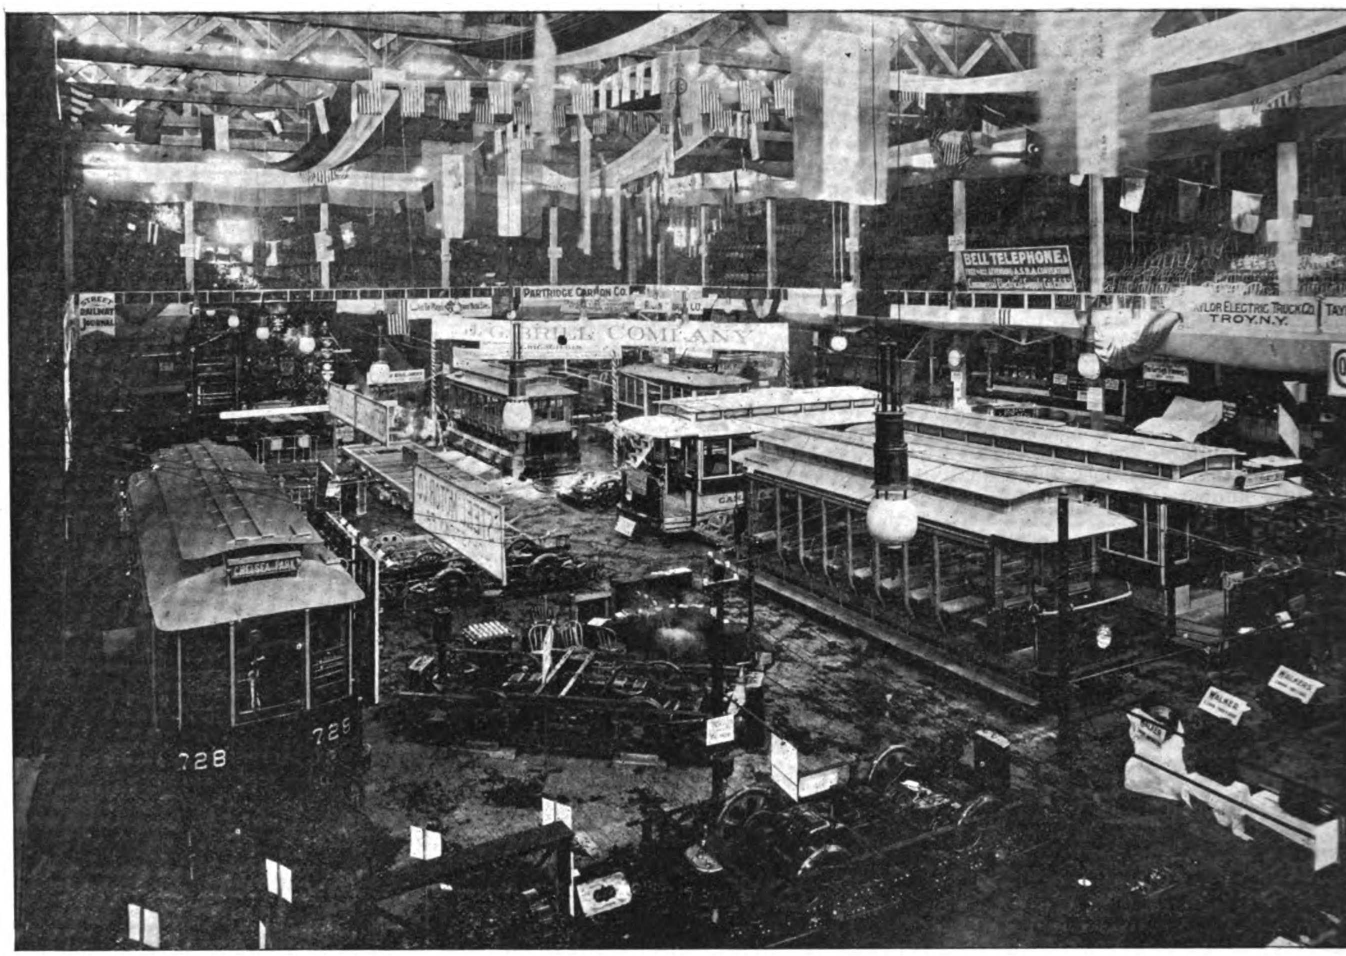
THE WESTERN TELEPHONE CONSTRUCTION COMPANY, Chicago, was represented by Mr. Charles P. Platt. This company showed one of their new type 100 drop switchboards, fully equipped; also a number of samples of telephones and other apparatus of this description, manufactured by this progressive company. This exhibit attracted considerable attention owing to its tasteful arrangement.

THE INTERNATIONAL REGISTER COMPANY, of Chicago, was represented by Mr. A. H. Woodward, treasurer and manager, and Mr. A. H. Englund, secretary. This company had a complete line of their portable and stationary registers. Amongst the latter was shown their new double register for cash fares and transfers, which attracted considerable attention.

THE AMERICAN CAR COMPANY, of St. Louis, had an excellent display, under the supervision of its president, Mr. W. Sutton, one of the pioneers of car building in the West. It consisted of three cars in the latest style of the art, one being a double truck and two single trucks. There was also a high speed motor truck specially intended for high speed suburban work. The olive bodied car built for New Orleans elicited very favorable comment.

THE MISSISSIPPI GLASS COMPANY, St. Louis, had a line of fire brick suitable for high grade boiler and furnace work. They also showed a fine line of Florentine glass, to be used for deck lights, for street car work, and for all kinds of glass partitions. A unique part of this exhibit consisted in some specimens of their wire glass, in which a strong metallic netting is embedded in the glass. This is done while the glass is in a molten state, and when the glass is ready for use it adheres so firmly to the wire that if broken by shock, by fire, or from other causes it remains practically intact, as, although the glass may get cracked all over, it will still firmly adhere to the wire netting unless a force sufficiently severe to break the netting is used. The manufacturers of this glass claim that it is practically fire and burglar proof, and can be advantageously used for quite a large variety of purposes. Mr. Charles W. Parker had charge of the exhibit and received a large number of interested callers.

THE PECKHAM MOTOR, TRUCK AND WHEEL COMPANY had an extensive exhibit, as usual, with Mr. Peckham directing it. In the exhibition hall there were a No. 7 C Excelsior truck, one of 175, now building for the Cincinnati Street Railway, and fitted with the Kilgour emergency brake and General Electric "No. 1,000" motors; an extra long truck, with Walker No. 10 motors; another similar with Westinghouse No. 12 A motors; another with General Electric "No. 1,000" motors, and one with Westinghouse No. 38 B motors. There were also an "extra long" truck under a 20-foot closed car body; a No. 14



EXHIBITS AT THE STREET RAILWAY CONVENTION, ST. LOUIS.

double-cushioned swivel truck, and a "standard" No. 8 A truck with new type extension trusses. In operation on the street railway systems the company showed a pair of No. 14 trucks under a Jackson & Sharp 35-foot vestibuled combination car body, with the bottom of the sills only 27½ inches from the ground. This was fitted with General Electric No. 1,200 motors and Hunt airbrakes. Mr. Hanna was in general charge of the whole exhibit, and maintained hospitable parlors also at the Southern, besides distributing a large quantity of literature.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, of St. Louis, had one of their large converters on exhibition in the space of the Commercial Electric Supply Company and Mr. E. H. Abadie was in attendance at the hall and the hotels to meet his numerous friends.

K. McLENNAN & CO., of Chicago, through their indefatigable agent, Mr. Isaacs, issued a large number of State warrants in the case of the company versus users of generator and motors. Messrs. Sparking and Cutting were arrested by one application of Gale's commutator compound.

THE NEW HAVEN REGISTER COMPANY, New Haven, Conn., exhibited a line of their single, double and triple street car registers. Mr. A. N. Loper, their traveling salesman, was in charge. Mr. F. C. Boyd, vice-president and general manager, and Mr. Willis Anthony were also around.

FLETCHER & STONE, of St. Louis, showed an automatic cut-out for releasing a broken trolley wire, so that should the trolley wire break, it immediately becomes dead. They also showed a flexible hanger, the object of which is to overcome the crystallization of the trolley wire where it enters the cars.

MR. F. W. DARLINGTON, E. E., of Philadelphia, distributed an attractive pamphlet entitled, "Electric Illuminated Fountains," dealing with his work at Willow Park, recently illustrated and described in The Electrical Engineer. He has been making a specialty of this in connection with electric railways, to whose pleasure parks is thus added a highly popular and remunerative feature.

MR. ARTHUR S. PARTRIDGE, of St. Louis, had a tastefully decorated booth, in which were displayed a full line of the specialties of R. D. Nuttall & Co., of Allegheny, Pa. Mr. Partridge represents a number of other interests in the West, whose exhibits were in various parts of the hall, and were complete in themselves.

W. W. DOTY & CO., of New York City, exhibited the Doty-MacKnight automatic track switch for electric surface roads. The switch consists of a double solenoid mechanism and a current reversing switch, all being contained in a box placed in the track bed under the switch tongue. The box is about three feet deep, and eighteen inches wide. The section of track immediately adjacent is insulated and the operating current is applied from the line through the controller. All the wearing parts are of heavy, solid metal. On approaching the switch, if the motorman sees that the tongue is right for him, he shuts off his current, allowing his car to skid over the insulated section. If the tongue is over the wrong way for his direction of travel he leaves the current on and the switch is at once thrown across.

THE STEEL MOTOR COMPANY, of Johnstown, Pa., were represented by George W. Henry, general sale agent, 1,505 Monadnock block, Chicago, and Eug. C. Parham, electrician of the company. No exhibit attracted and held more attention or excited more interest than that of the company. Mounted on a Dupont truck, now winning much favor, for its simplicity and durability, were two C No. 3½ steel motors, operated by two C No. 3 controllers. The C 3½ motors are the latest, tested and tried production of these pioneer makers of steel motors. The motor is constructed upon substantial lines, has never failed to convince the most skeptical street railway man of its staying powers and durability, and enjoys the distinction of offering easy access to any one part without disturbing any other. The C No. 3 controller is of the series parallel type, with the usual locking and interlocking devices, but has the "unique" feature that the motor cut-outs are incorporated within the control of the reverse lever, making it unnecessary to open the controller to cut out a motor. This innovation seems to have been indorsed by technical admirers and by the many practical motormen who availed themselves of the opportunity to witness and also try its operation. The steel motor exhibit was a "hit," and its businesslike, "get there" aspect created a favorable impression.

THE J. G. BRILL COMPANY had a superb exhibit covering a very large section of the main floor, and illustrating the great versatility and resource of that celebrated concern. One of the leading features was an open car on the No. 21 E truck, and having a specially designed curved panel for the seat ends, the object being to render ingress and egress easier. Another 21 E truck was shown unequipped; also the latest maximum traction truck, which enables a double truck to be dropped low enough to permit of using only one step. No. 27 truck shown is a new departure in electric car service, for high speed work, and is of the style used as a standard by the Buffalo-Niagara Falls road, the Akron and Cleveland, the Cleveland, Painesville and Western and others. The idea is that instead of having the springs lining with the track they are carried outside. A remarkably flexible truck is gained by this method of disposing of the spring links. Owing to the increased speed of the links there is a greater stability of the car body. The car has less inclination to roll, the passengers have less difficulty in dismounting and more pleasure while riding, and the mechanism is far less liable to feel strain or shock. It is evident that with so many springs and equalizers the car motion must be very easy. It is said that sixty miles an hour is made comfortably. There were also shown a snow plow for cleaning snow off double track, a sweeper with separate motor on the rotary brooms and a sprinkler with a capacity of 3,200 gallons. The company had also a parlor at the hotel for their friends, and were represented by Vice-President J. G. Brill, Assistant General Manager S. M. Curwen, F. C. Randall, W. H. Hulings and G. M. Haskell.

THE STANDARD AIRBRAKE COMPANY, of New York, represented by Mr. E. J. Wessels, their general manager, and by Mr. Merriam, their engineer, had a splendid exhibit of their system, which, distinctively a pioneer in the application of power brakes, remains to-day a highly progressive leader in this important field. The exhibit included their apparatus as it exists in its latest forms and as illustrated in the special types built for the Cleveland and Akron road and for the Leipzig, Germany, street car system. A most fascinating exhibit was that which, in contrast with their single-acting and geared types of compressors, was devoted to exhibiting their electric motor compressor. This is used in conjunction with a very ingenious and simple automatic controlling device, which, within the predetermined limits, takes care of the maintenance of the air pressure, and sets the motor to work, compressing the moment the single needle dial on the brake handle stem shows the lower limit, cutting off the trolley circuit to the motor the moment the compressor is again at the right point of charge. Nothing prettier or more convincing to watch could be imagined. Associated with the exhibit were some decidedly effective whistles, while the whole space was railed by brake handle standards, as placed on the platforms against the dashboards, and connected up by the couplings and pipes used for hitching on trailers so as to make the braking effective and instantaneous throughout the train. The company had some pithy and pointed literature to distribute, including its latest catalogues and the well-known discussion of the subject by Mr. Wessels, a paper which still serves as an arsenal of formidable and irrefutable arguments for power braking on street railways.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY.—The exhibit of the Westinghouse Electric and Manufacturing Company was in the midddle of the hall, where this well-known company had a display of motors, switchboard apparatus and sundry literature. Among the motors, the No. 12 and 38 B, mounted on Peckham trucks and on a Brill Company snow sweeper attracted general attention. The particular novelty, however, of the Westinghouse exhibit, and from an electrical point of view, the most interesting part, it might be said, of the entire exhibition, was the display of Wurts switches and circuit breakers. These appliances are of recent design, and embody some very novel features of improvement, which strongly appealed to the practical men, who manage the power house, and who are engaged in the operation and attendance of the generators and switchboards. The chief characteristics of the switches, which were especially commented upon, were their enormous carrying capacity and ease of operation, as compared with older types. The company manufactures these appliances up to 3,000 ampere capacity. The circuit breakers are of equally easy operation. They have copper carbon shunts, preventing all possibility of burning at main contact points. It has a releasing device without the use of the solenoid. Means of adjustment are sliding weights over scale arm. These instruments were shown on a two-panel switchboard, one being a 2,000-ampere generator panel, and the other a 1,200 feeder panel. In addition to these instruments the exhibit also contains samples of the well-known Wurts non-arcing lightning arresters, tank arresters, as well as pyramidal arrester for high potential transmission circuits. The company was represented as strongly as on any previous convention, those present being G. H. Lewars, Albert Schmid, W. F. Zimmerman, C. E. Bragg, A. J. Wurts, H. P. Davis, A. Hartwell, J. A. Rutherford, C. E. Skinner, T. A. Cleland, H. C. Ebert, M. Coster, W. R. Brown, A. F. Gordon, N. W. Storer and E. H. Heinrichs.

THE WELLS & FRENCH COMPANY, of Chicago, exhibited their "Chicago" truck.

THE CROCKER-WHEELER ELECTRIC COMPANY were represented my Mr. H. L. Lufkin.

LINBURG, SICKEL & CO., of Trenton, had on the main floor one of their Trenton trolley wagons of the standard make, now familiar to the street railway public.

WENDELL & McDUFFIE, of New York City, well known for their street railway specialties, were represented by both the young and energetic members of the firm.

IVES AND MACCLERNAN, of Baltimore, represented the Leonhardt Wagon Manufacturing Company, and had three of their excellent revolving tower wagons on view, illustrating different sizes and other features to great advantage.

THE STORAGE BATTERY COMPANY OF AMERICA were well represented by Messrs. Lloyd, Condict, Williams and Arnold. The deep interest taken by railway managers in the battery as a part of station and line equipment sufficiently explains the presence of such a strong force.

FORD & BACON, engineers, of New York City, were represented by Mr. Ford, who was able to show one of the cars built under their specifications by the Amer. Car Company for the Canal & Claiborne Railway Company of New Orleans, one feature of these being the 2 inches greater length given to the cross-seats by means of the style of end panel adopted.

THE MARK RAILWAY EQUIPMENT COMPANY, of Chicago, represented by C. E. Mark, president, showed their excellent joint bridges as applied to the rails of a large number of well known roads. The support given to the rail, especially as it reinforces the head and beam can result only in greater durability and smoother running.

THEBROWNELL CAR COMPANY, of St. Louis, had a large car on view, unusually high, having a flight of three steps. It is intended for the Metropolitan road of Kansas C'ty and will stop at platforms, hence its great height from the ground. A special feature is the opening and closing of the gates by means of a small handle on the motorman's right side close to the dashboard. The car was a beautiful type of its class. It was supplemented by a light Brownell car truck.

THE WHITE-CROSBY COMPANY, represented by Mr. Hugh Harrison, had a remarkably interesting exhibit—none other than a full size head, of one of the Niagara-Buffalo pole lines that they are building; an article on-which appears elsewhere in this issue. The pole carried its regular cross-arms, with Imperial porcelain three-cup insulators, American Electrical Works bare copper wire, guard wires, fuse wires and provision for telephone service. The cross-arms were also shown properly braced and all the details were faithfully carried out.

THE KRAUSHAAR LAMP AND REFLECTOR COMPANY, of St. Louis, had a magnificent exhibit in the shape of a mammoth board draped in dark cloth, on which were grouped in a most clever and artistic manner a number of designs and trophies, all built up out of street railway material, chiefly brass. The effect was simply superb. Stars, crescents, shields, tendrils, borders, flourishes dazzled like gold, and it was amusing to note on close inspection that plain, ordinary brake handles, window lifts, hinges, scrolls, lock escutcheons and other familiar parts were all that the ingenious artist had had to work with.

THE ELECTRIC RAILWAY EQUIPMENT COMPANY, of Cincinnati, was unable to make its intended exhibit owing to sickness in the family of Mr. S. J. Wick. The company was, however, worthily represented by Mr. E. P. Morris, New York agent, and by Mr. W. R. Mason, of the Mason Electric Equipment Company, Chicago agent. This company is making a specialty of electric railway supplies, and its manufacturing facilities are such that it is enabled to furnish everything used either for the equipment or maintenance of such roads. The most careful and exhaustive tests for strength and insulation are made, and as a result the company is enabled to guarantee all material.

THE AMERICAN CAR COMPANY'S car, containing the "H. W. J." electric heaters, was notable as illustrating several other novelties, such as the new cane seats and seat stands of the Scarritt Furniture Company and the National airbrake, which depends only on the car for its power and makes no draft on the line. Another feature which is certain of universal adoption before long, was that of the electric push button to each seat, so that the passenger has no trouble in signaling the conductor when wanting to get off. In this case the pushes were mother-of-pearl, mounted in nickel rims. The provision of such luxury evinces of a liberal management that draws travel where a parsimonious management repels it.

MR. EDMOND VERSTRAETE, a well known railway pioneer, and now president of the Missouri Brass Type Foundry Company, of St. Louis, had on exhibition on one of the fine steel trucks of the St. Louis Car Company, his improved electric brake, which works on current from the line, brought through an asbestos boxed resistance and energizing a solenoid magnet, the pull on which instantly sets the brakes, by means of a chain communicating from the magnet to the brake bar. The magnet is small and is placed under the front part of the car. It will lift 1,200 pounds from the ground, and hence will be seen to have a very positive action when operating a brake. The brake chain and plunger run in a graphite casing inside the solenoid. Some of these brakes are in use on the St. Louis Suburban.

THE H. W. J. ELECTRIC HEATER, made by the H. W. Johns Manufacturing Company, was shown in a full equipment in a beautiful car made by the American Car Company, of St. Louis. These heaters, which have already been described in The Electrical Engineer, were placed longitudinally against the sides of the car. These heaters need only screws to fasten them to the woodwork, and, being very flat, literally occupy no space, while the principle of multiplicity provides that general distribution, which is so necessary, but which no stove can give. The company also showed in connection with this set one of their switches for throwing the current on and off the heaters, so arranged as to lock at each step, and being remarkably compact and correct in its design. The company had an exhibit in another part of the hall of its heater arranged to go crosswise under seats. The literature distributed was pithy and to the point, and the company were most energetically and intelligently represented by Mr. J. Emery Meek.

THE WALKER ELECTRICAL MANUFACTURING COMPANY had a well selected and representative exhibit on the main floor, under the care of Mr. J. Holt Gates, of Chicago, and Mr. W. J. Davison, engineer of the company in Cleveland. One of its main features was the type of armature for the fifteen generators ordered by the Chicago City Railway Company, each of 800 k. w. These are to be rope-driven at 220 revolutions. They are 10-pole machines, with 40 brushes and 3 bearings, and weigh 61 tons complete. The exhibit included also one 75 h. p. railway motor (3,000 pounds drawbar pull), one 50 h. p. (2,000 pounds), one 35 h. p. (1,200 pounds), one 25 h. p. (800 pounds). The controllers included also the new type E 1, the feature of which is that the current is broken up in 28 points, by means of a separate cylinder, instead of using a magnetic blow-out. It has also a separate reversing and controlling cylinder. Armatures for the various types of railway motors were also shown, and the exhibit was rounded out with a handsome Peckham truck equipped with two 25 h. p. motors; as well as by a run of overhead wire fitted with the new Walker overhead pull-overs, ears, clamps, etc., and the interesting and ingenious Walker roller trolley adjusted to show how it runs under a switch.

THE CENTRAL ELECTRIC COMPANY, with the co-operation of its healthy St. Louis concern, the Southern Electrical Supply Company, made an exhibit which was surpassed by none for taste and comprehensiveness, and which was for its space decidedly the prettiest in the building. It had a large booth all draped and roofed with the Stars and Stripes, and neat fence around, with railings, on which some of the goods were placed. There was a brilliant setting of colored incandescent lamps, accentuated here and there by headlights of dazzling ray. The walls of the booth were lined by a generous collection of railway material, all grouped and posed to secure the greatest artistic effect. Among the special decorative panels may be mentioned one of the ingenious and effective Garton arresters, another showing Billings & Spencer railway specialties and copper goods, one of mica for electrical purposes, one of a neat group of the Partridge carbon brushes, one of the interior conduit system, and one showing in array the Bound Brook trolley, motor and other graphite bushings. These were all set off by lamps and made an effective combination. There were also shown a table of samples of Okonite cables and feed wires and a section of the new interior conduit insulating subway pipe. Two lighting novelties drew the attention of everybody. One was the detachable lamp for cars made by the Changeable Headlight Company, so made that one light would serve for both ends of a car, being transferred to and from boxes into which the headlight slips and locks. The change is made positively and easily in a single moment. Each box, when not occupied by the lamp, is closed by a little flanged lid. The other lighting device is the new Benjamin weatherproof and waterproof socket, made in three styles. Its mechanism is simple and its use on such exposed places as the platforms of the Chicago Metropolitan stations, shows how thoroughly it can be depended on. The Central Electric Company were vigilantly represented by Messrs. W. R. Garton, E. E. White, Malcolm McNeill and C. W. Cobb.

HALE & KILBURN, of Philadelphia, showed a full line of their well known seats and chairs for the equipment of street cars.

THE CONSOLIDATED CAR FENDER COMPANY had a full sized model of a car fitted with their car fender at both ends.

MR. C. D. SHAIN was present in the interests of the Siemens & Halske Electric Company, and the Weston Instrument Company.

THE JOHN STEPHENSON COMPANY had no cars on view, but distributed to their many friends a neat vest pocket memorandum book.

THE SCARRITT FURNITURE COMPANY, of St. Louis, had a very handsome exhibit of their various designs in car seats, chairs, reversible seats, etc.

MISSOURI MALLEABLE IRON COMPANY, of St. Louis, showed a few samples of castings for railway fittings, such as drawbars, axle boxes, truck frames, etc.

J. H. WOLF & CO., of St. Louis, were represented by Mr. Wolf, who interested delegates in a new transfer ticket which is easily read, and avoids all danger of disputes.

THE POND MACHINERY COMPANY, of St. Louis, exhibited a full line of their celebrated steam separators for furnishing dry steam to engines in electric light and power plants.

THE SARGENT COMPANY, of Chicago, were represented by Mr. E. L. Adreon, who showed a few interesting samples of brakeshoe, and other steel castings for street railway purposes.

E. M. DAVIS, of St. Louis, showed a working model of his automatic switch thrower, by which the switch can be flung automatically in any direction by a mechanical device set in front of the motorman.

THE MISSOURI CAR AND FOUNDRY COMPANY, of St. Louis, were represented by Mr. James Connolly, who had on exhibition car wheels, cable pulleys, chilled brakeshoes, brasses and other street railway fittings.

L. A. CHASE & CO., of Boston, were represented by Mr. S. B. Condit, who had something interesting to say on the subject of repairs. Mr. Condit was and is looking for a few good specialties to represent in the East.

THE CRANE COMPANY, of Chicago, were represented by Mr. J. B. Berryman and G. A. Hurd, who had an interesting exhibit of valves and fittings for high pressure work, suitable for the equipment of street railway power plants.

BRADFORD BELTING COMPANY, of Cincinnati, were represented by Mr. O. M. Hubbard, who showed samples of Monarch paint, and other electrical specialties, for which they have become well and favorably known in the West.

THE ROCHESTER CAR WHEEL WORKS were actively represented, as usual, by Mr. Russell, who had with him as a souvenir something that would very effectively remind the friends of the works that their wheels are true as steel.

ELMER P. MORRIS of New York, representing Monarch insulating paint, and general electric supplies, attended the convention and distributed also a large number of samples of Monarch war paint for internal use, put up in small glass barrels.

THE AMERICAN ELECTRICAL WORKS, of Providence, R. I., were represented by Mr. P. C. Ackerman, of New York, and F. E. Donohoe, of Chicago, who said that their exhibit was all over the city in the shape of feeder wire in actual service.

SHICKLE, HARRISON & HOWARD IRON CO., of St. Louis, were represented by Mr. James Daniels, secretary of the company, and T. M. Gallagher, vice-president. They showed samples of their steel gears for electric railways and all classes of steel castings for cars and truck frames.

THE WATERTOWN ENGINE COMPANY, of Watertown, N. Y., were represented by the Pond Machinery Company, of St. Louis, and showed model of their electric light engine governor and called special attention to their exhibit of engines in operation in the St. Louis Exposition building.

D. C. SWEET, of Springfield, Mass., showed two styles of his car wheel grinder, fitted with corundum wheels made by the Hampden Corundum Wheel Company, of Springfield, Mass., for trueing up car wheels which show flat spots after service. The wheels need not be removed from the car.

JOHN T. McROY, of Chicago, showed examples of his vitrified terra cotta conduit, the two, three, four and six-duct styles being represented. The samples were well glazed, perfectly smooth on the inside, and appeared well adapted for their purpose. Mr. McRoy had some very interesting letters of testimonial in his pocket, from companies for which he has done work, which reflect great credit on his system.

MR. J. L. BLACK showed a model of his automatic fulcrum hand brake. Mr. Black claims that this brake will stop with a single turn of the handle one of the longest street cars fully loaded in a space of fifty feet. It is very simple in construction and cars can be equipped with this brake at quite a small cost.

K. McLENNAN & CO., of Chicago, were represented by Mr. M. J. Isaacs, who showed samples of their well known Gale's Commutator compound, from the use of which a great saving in the wear of commutator and brushes is guaranteed, absolutely preventing sparking and cutting and not gumming the brushes.

INTERIOR CONDUIT AND INSULATION COMPANY, of New York, were represented by Mr. E. B. Kittle, who had an interesting exhibit of their underground and interior conduits, showing full details of the system. Mr. Kittle had also a parlor on the Southern Hotel, where he showed a few samples of their specialties, and had every means at his disposal for the entertainment of his friends.

THE HYATT ROLLER BEARING COMPANY, of Newark, N. J., and New York, showed a few samples of their flexible roller bearings as applied to car boxes, shafting hangers and pillow blocks. They also had a set of their flexible bearings on one of the trucks of the General Electric Company's exhibit. The company was represented by Mr. F. V. M. Hudson, of New York.

THE NATIONAL WATER TUBE BOILER COMPANY showed a very handsome model of a boiler complete, with brickwork , made to scale, with side removed, to show interior construction. They also showed a full size header, a model of a Standard rocking grate bar, and other special features of their boiler. They were represented by Mr. Frank H. Pond, manager of the St. Louis office.

THE COLUMBIA MACHINE WORKS, of Brooklyn, N. Y., were represented by Mr. J. G. Buehler, of Brooklyn, who showed samples of their drop forged bars for commutators, self-oiling trolley wheels, patent adjustable controller handle, reversible and interchangeable armature bearings and car trimmings of all descriptions. Repairs and rewinding of armatures are a specialty of this company.

THE ST. LOUIS CAR WHEEL COMPANY had a handsome exhibit of all classes of street car wheels, hammered steel and iron axles, of all the standard sizes for street railway purposes. They also showed a large collection of specimens of charcoal car wheel irons, attesting the different depth of chill. They were represented by Mr. R. W. Green, secretary of the company, and Mr. J. W. Nute, general agent.

THE MUNSON ELECTRIC CONDUIT COMPANY were represented by Mr. John H. Munson and William F. Roberts, who had a working model of their system on exhibition, which attracted great attention. They had a section of track about thirty feet long, including a sharp curve, on which they had a model car equipped with their device and operated electrically. This system has many points of advantage, the motor car being always in contact, and the contact points being only alive immediately under the car.

THE COMMERCIAL ELECTRICAL SUPPLY COMPANY, of St. Louis, had a most complete exhibit of electrical supplies, and represented at the convention hall the following companies: The Bryant Electric Company, lighting supplies; Clifton Manufacturing Company, friction tape; Electrical Engineering and Supply Company, street railway supplies; Holmes, Booth & Hayden, weatherproof wire; Hugo Reisinger, "Electra" carbons; India Rubber and Gutta Percha Insulating Company, Habirshaw Wires and cables; Perkins Electric Switch Manufacturing Company, switches and lamps; Pass & Seymour, porcelains; W. T. C. MacAllen, street railway material; Standard Paint Company, P. & B. paint; Western Electric Company, railway material; Wagner Electric Manufacturing Company, switches, and the St. Louis Car Heater Company, electric heaters, and A. O. Schoonmaker, mica. The company were represented by Messrs. P. D. Cable, V. E. Raggio, and J. B. O'Brien. The company had a magnificent exhibit of all kinds of electrical supplies and specialties, the exhibit being arranged with great taste. At the head was a large board covered with Pass & Seymour porcelains, while all around was a profusion of switches, railroad apparatus, instruments, wire, converters, insulators and everything necessary for the equipment of an electric plant, either for lighting, railway or power purposes. An interesting sample of cable shown was a piece cut from the cable supplied to the Niagara Falls Company, of Habirshaw manufacture, the cable being 3,769,000 circular mils, and insulated with white core.

HOLMES, BOOTH & HAYDENS were represented by Mr. J. O. Crane.

THE CAMPBELL & ZELL BOILER COMPANY were represented by Mr. J. Vernon Campbell.

MR. T. H. DICKINSON was present in the interests of the New York Packing and Belting Company.

DUSENBURY & BOND, of New York, exhibited a full line of carriage trimmings suitable for electric cars.

THE TRIUMPH ELECTRIC COMPANY were represented by Mr. J. C. Hobart, of their Cincinnati office.

THE AKRON INSULATION AND MARBLE COMPANY had a representative in the person of Mr. A. L. Daniels.

THE TAUNTON LOCOMOTIVE MANUFACTURING CO., whose snow plows are so well known, were represented by Mr. R. L. McDuffie.

THE McGUIRE MANUFACTURING COMPANY, of Chicago, had a choice exhibit of their trucks, etc., and a large snow-sweeper outside the building.

THE MORRELL ELECTRIC WORKS, of St. Louis, showed a few commutators, which they make a specialty of supplying to electric railways.

BILLINGS & SPENCER, of Hartford, were represented by Mr. W. B. Post, who showed samples of their well known drop forged commutator bars.

THE BRUSSELS TAPESTRY COMPANY, Chauncey, N. J., showed some beautiful samples of their textile fabrics, suitable for street car windows and curtain fixtures.

MR. LUTHER STIERINGER was one of the prominent electrical engineers present, to make note of the drift of events and throw his influence on the side of good work.

THE AMERICAN ELECTRIC HEATING CORPORATION, of Boston, touch a side of the industry of deep interest to the street railway man, and hence Mr. T. P. Luther found little leisure as their mouthpiece.

THE PERU ELECTRIC MANUFACTURING COMPANY were on the ground in the person of Mr. R. H. Bouslog, who had many friends and customers to see in regard to inquiries for their excellent specialties.

THE SHULTZ BELTING COMPANY had a neat little exhibit of their belting in the gallery, and were represented by Capt. Shultz and the Messrs. Alvord. They still believe in leather, even for the electrical industries.

THE STEEL RAIL part of the business was very adequately represented in the displays of the Johnson Company and the Pennnsylvania Steel Company. There were a number of joint, frog and switch exhibits of the usual character.

THE SAFETY INSULATED WIRE AND CABLE COMPANY were represented by Mr. E. D. Draffen, who had some striking data as to the enormous quantities of "Safety" cable that have been used in street railway construction.

THE WASHBURN & MOEN MANUFACTURING COMPANY, of Worcester, Mass., were represented by Mr. C. H. May, who showed some attractive samples of lead-covered cables, figure 8 trolley wire, a full line of rubber covered wires, submarine cables, magnet wire, lamp cord, weather proof wires, trolley springs, car springs and the Chicago rail bond.

E. T. BURROWES COMPANY, of Portland, Me., showed some handsome models on which were displayed samples of their automatic curtains for both open and closed street cars. They also showed a full line of curtain materials and curtain fixtures, including the water-proof material, Oakette, in twenty different patterns. Mr. H. H. Russell, of Portland, represented the company.

THE PARTRIDGE CARBON COMPANY, of Sandusky, Ohio, had an attractive booth decorated with a handsome framework, displaying large engravings of their well known Partridge self-lubricating motor brush. Mr. J. S. Speers, secretary of the company, was in attendance, and showed to all interested samples of their product varying in size from the smallest fan motor brush to the largest generator brush.

STANDARD PAINT COMPANY, of New York, were represented by Mr. J. C. Shainwald, of Chicago, their Western manager; Mr. C. D. Jones, also of the Chicago office, and R. J. Redick, of St. Louis. Mr. Shainwald and his exhibit with that of the Commercial Electric Supply Company, of St. Louis, had the usual amount of literature, and was calling attention to the new P. & B. motor cloth manufactured by this company.

BOWERS BROTHERS, of Chicago, had an interesting exhibit of solid sheet mica rings, segments, washers, different grades of uncut India and amber mica, used by the electrical trade for insulation. An unusually large sheet was shown that would be difficult to duplicate, being one of the largest in the United States, and a very interesting exhibit was a sheet of mica mined in 1832, being part of the first mica got out in this country. The exhibit was in charge of Mr. E. S. Bowers, of Chicago.

THE M. M. BUCK MANUFACTURING COMPANY, of St. Louis, had a large and interesting exhibit of railway supplies of every description. This company are agents for Charles A. Schieren & Company's belts; rainbow rubber belting, manufactured by the Peerless Rubber Company, of New York; the Shaw patent shaft coupling, manufactured by Patterson, Gottfried & Hunter, of New York, and a number of other valuable specialties too numerous to mention, but which are all necessary to the street railway engineer.

H. W. JOHNS MANUFACTURING COMPANY, of New York, were represented by Mr. E. B. Hatch, of Hartford, Mr. J. E. Meek, of New York, and Mr. McLennan, of St. Louis. They made an exhibit of their electric car heaters in various designs, suitable for either side or cross-seats, and also some of their latest novelties in trolley line devices, among which special attention was called to their new mechanical clip for 8-shaped trolley wire. It is interesting to note also that the car exhibited by the American Car Company, of St. Louis, was equipped with the H. W. Johns heater, as mentioned elsewhere.

THE CENTRAL UNION BRASS COMPANY, of St. Louis, were represented by T. C. White, of St. Louis. They showed a sample board handsomely equipped with street car trimmings, bearings, gear and pinion wheels, brake handles and other specialties. This company also showed samples of the manufactures of the Washburn & Moen Manufacturing Company, mica specialties, of Bowens Brothers, of Chicago; commutator bars from Billings & Spencer, of Hartford, and carbons of the Solar Carbon Company, of Pittsburg. They also represent A. Groetzinger & Sons, of Allegheny City, and showed samples of their rawhide pinions and blanks.

THE HEINE SAFETY BOILER COMPANY, of St. Louis, showed a full size 50 h. p. Heine safety boiler, without any brickwork, so as to exhibit the interior construction, the shell, water legs and tubes being finished in bronze and presenting a very attractive appearance. They also showed a model of a 250 h. p. boiler, one-sixth the actual size, finished complete with mountings, front and brickwork, the heads being made so that they can be readily removed for interior inspection. A water leg of a 200 h. p. boiler was also exhibited, which was taken from the regular shop stock, showing the general excellence of their construction and workmanship. The company was represented by Mr. S. D. Merton, secretary of the company, Mr. Russell Walker, the Cincinnati agent, and Mr. H. C. Meinholtz, superintendent.

MR. HAROLD P. BROWN, of New York, attended the convention and was assisted in showing his extremely interesting exhibit of plastic bonds by Mr. J. S. Tritle, of St. Louis. They showed a case in which were a number of bonds which exemplified in a striking manner the way not to bond, as based on a large series of experiments by Mr. Brown. The plastic bond was also shown as applied to different types of rail. The whole exhibit attracted wide attention, as the plastic bond is so entirely different from any other bond manufactured. It is claimed that with this bond a 90-pound rail will cause a drop of but 0.0045 volts, with 1,000 amperes, remaining perfectly cold. Mr. Brown has a vast amount of interesting information on the subject of bonding, and on tests for drop of potential in all existing methods of bonding rails.

EUGENE MUNSELL & CO.—The exhibit of Eugene Munsell & Co., miners and importers of mica, New York and Chicago, consisted of India and amber mica in a variety of forms. Large, clear sheets untrimmed, as they get in direct from the mines, mica segments, for all the standard railway motors, mica washers, carefully selected India and amber mica cut to size for electrical insulation, rheostat mica, etc., etc. The exhibit of drop forge commutator segments, for which the company are general selling agents, attracted considerable attention on account of the excellent quality of drop forgings exhibited. The blotters, which were distributed on the writing desks in all of the hotels, and at the places of registration in the convention hall, did effective work, as they conveyed to the visiting delegates the fact that the exhibit was one of special interest, and that the mica was received direct from the mines by the burro, or mule, having several large packages strapped on his back. The little mica souvenir which was given away, was well received, and no doubt will be taken home by a large number of the visiting delegates. Many were seen wearing them in the lapel of their coats. The exhibit was displayed in connection with that of the Mica Insulator Company, and the company were represented by Mr. Henry C. Onick, of the Chicago house. The firm's representative in St. Louis is Mr. Arthur S. Partridge, well known to the railway fraternity.

THE CHAPMAN VALVE COMPANY, whose specialty can be seen in so many electrical power plants, had a few of their valves on exhibitions.

BABCOCK & WILCOX boilers were represented by Messrs. Ashburner and Bonner, both well armed with arguments in behalf of that favorite specialty.

THE Q. & C. COMPANY, of Chicago, made an interesting working exhibit of two of their special machines for sawing through rails, an invaluable machine in track construction.

THE CHAPMAN VALVE MANUFACTURING COMPANY showed a complete set of their well-known make of valves suitable for street railway, electric lighting and power stations.

GEORGE P. JONES CO., St. Louis, showed a neat assortment of their oils and greases which are suitable for electric lighting, power and railway work. The exhibit was in charge of Mr. George Higgins.

THE DUFF MANUFACTURING COMPANY, Allegheny, Pa., had a line of their make of the Barrett patent compound lever truck, and oil well jacks. Their automatic liftiang jack No. 2 is used extensively on electric and cable car lines, and is very simple to operate.

MR. W. R. MASON, who has always been a prominent figure at conventions, was to the fore as usual in the interests of the Mason Electric Equipment Company, Chicago; the Fiberite Company, Mechanicville, N. Y., and the Electric Railway Equipment Company, Cincinnati, O.

THE NEW YORK CAR WHEEL WORKS, Buffalo, N. Y., exhibited some sets of their make of wheels for street cars and in the same exhibit were also shown some specimens of the Corning brake shoe, which is manufactured by the Corning Brake Shoe Company, Buffalo, N. Y.

THE NATIONAL LEAD COMPANY, New York, had a very tasteful exhibit which consisted of a complete line of their well-known solder, string solder, and Babbitt metal goods, and they distributed small metal souvenirs. They also had some of their make of white lead and paints. Mr. A. Benzel was in charge.

THE MURPHY VARNISH COMPANY displayed a full line of their well-known brands of varnishes, and had also several specimens of copal, amongst them being one monster piece of kauri gum copal, which they imported from New Zealand, its weight amounting to 100 lbs. This is supposed to be the largest piece of copal in the country.

THE GARTON-DANIELS ELECTRIC COMPANY, Keokuk, Iowa, was represented by Mr. J. V. E. Titus, and although this concern did not have any exhibit of its own, their latest and most improved types of lightning arresters were placed in such a very conspicuous position in the fine booth of the Central Electric Company, who are their agents, that they could not fail to attract the attention of the callers to the exhibit.

THE FOREST CITY ELECTRIC COMPANY, of Cleveland, were represented by Mr. W. B. Cleveland, of Cleveland, and Mr. John C. Dalph, of New York. They had a handsome board, on which were mounted samples of their rolled drop and drop forged commutator bars, and also exhibited a sample rail joint, showing the Protective rail bond in place under the fish plate, and also a bond welder, illustrating the method of applying the bond.

THE BETHLEHEM IRON COMPANY, South Bethlehem, Pa., H. F. J. Porter and W. R. Colcord, agents, exhibited a superb hollow forged steel shaft, made of fluid compressed steel, intended for a direct coupled engine now being built for the Northwestern Elevated Railroad of Chicago, by E. P. Allis & Co., of Milwaukee. It is one of twelve now being supplied to different railway systems in Chicago, and would appear to have a large future in the lighting field as well.

THE GOLD STREET CAR HEATING COMPANY, New York and Chicago, showed one of their hot-water circulating heaters for street cars. This heater consists of a stove placed under the car, the smoke pipe passing out at the roof. The stove contains a pipe coil to which is connected a system of pipes running up into the car and around under the seats, by which means the heat is distributed to all parts of the car. The Gold Company also exhibited their several styles of electric heaters for cars, offices, dwellings, steamboats, etc. Mr. C. H. Gold, of the Chicago office, was in charge of the exhibit.

THE STANDARD UNDERGROUND CABLE COMPANY were represented by their Western manager, Mr. J. R. Wiley and Mr. F. C. Cosby, superintendent of construction, exhibited their usual line of handsome samples of lead-covered feeder wires, and cables, and weather proof wires, suitable for street railway and power work. A large reel of weather-proof feeder cable attracted attention as well as a unique souvenir, entitled "A reminder of Ohm's law." The Standard Company is arranging to open an office in St. Louis, in the Security Building, immediately, with Mr. F. C. Cosby in charge, so as to be located on the ground when underground matters shall have been settled, and will no doubt secure their proportion of the business to be done in the near future. Mr. J. R. Wiley has a large acquaintance amongst the wire-using companies in St. Louis, having formerly resided in that city.

THE PHŒNIX CARBON MANUFACTURING COMPANY, of St. Louis, had an attractive exhibit, presided over by Colonel S. G. Booker and Mr. H. I. Page, in which they displayed samples of their celebrated carbon specialties. They gave away a large number of carbon souvenirs, made of motor brush material, which illustrated in a marked degree the fine finish attainable by the methods used by this company, and they also gave away a special souvenir in the shape of a glass paper weight, with a picture of the Phœnix carbon on the back. They are at present making a specialty of motor and generator brushes, and had a huge illustration suspended over their exhibit of the Phœnix self-lubricating brush. They report business in their line exceptionally good, being now weeks behind in their orders. This company also make a specialty of all forms of battery carbons, and, in fact, of every kind of carbon used in the electrical business.

JOHN A. ROEBLING'S SONS COMPANY, Trenton, N. J., had an exhibit of their Columbia rail bond. This bond consists of three parts, two copper thimbles, and the connecting copper rod. On each end of the copper rod is a truncated cone head with a fillet at the base. The inside of the thimble is tapered to fit the head of the band, while the outside is slightly tapered in the opposite way. In applying the bond the cone-shaped heads are placed in the holes of the rail from one side, and the thimbles are slipped over them from the other. A portable hand press is then applied and the wedge-shaped head of the bond is forced into the thimble so that it is not possible to see the line separating the thimble and the head in a cross-section of the two. The end of the head of the bond is expanded by a center punch held in position in the press. The press is capable of giving a pressure of from 15 to 20 tons, and when the band is fixed in its place it practically becomes an integral part of the rail, so that it is impossible to twist the bond in the rail. This company claims that it makes the most perfect connection of any bond on the market. Mr. George C. Bailey and Mr. A. B. Conover, Jr., of the Chicago office, and Mr. W. M. Doyle, of Trenton, were around looking after the interests of their company. Mr. Shippy gave general supervision to all the company's large interests.

AN OCEAN CABLE MEMORIAL.

The International Submarine Telegraph Company has decided to initiate a submarine telegraph company memorial throughout the civilized world to honor Cyrus W. Field, who first conceived the ocean cable; Sir John Pender, who risked his capital, and Sir James Anderson, who captained the Great Eastern.

Lord Selborne announced that the scheme has the sanction and encouragement of the Queen.

The memorial will be a scholarship and a home for engineers. A great many well known Americans and Englishmen have lent their names to the plan.

OBITUARY.

H. E. COLLINS.

MR. H. E. COLLINS, senior member of the firm of H. E. Collins & Company, Pittsburg, died on October 14, at his late residence in the East End, Pittsburg. Mr. Collins was a native of New York State, but went to St. Louis at an early age to enter upon a general mercantile career. On the breaking out of the civil war Mr. Collins actively engaged in support of the Union cause, and remained at the front throughout the entire struggle, returning to St. Louis after the close of the war to become an adjuster of insurance losses. This occupation absorbed his entire attention for several years, when he became interested in various iron and steel enterprises in the vicinity of St. Louis, which gradually absorbed his attention to such an extent that he was obliged to abandon all other lines of business.

Having formed desirable connections in Pittsburg he removed to the latter city in 1876, where he founded the firm of H. E. Collins & Company, whose business was that of mer-

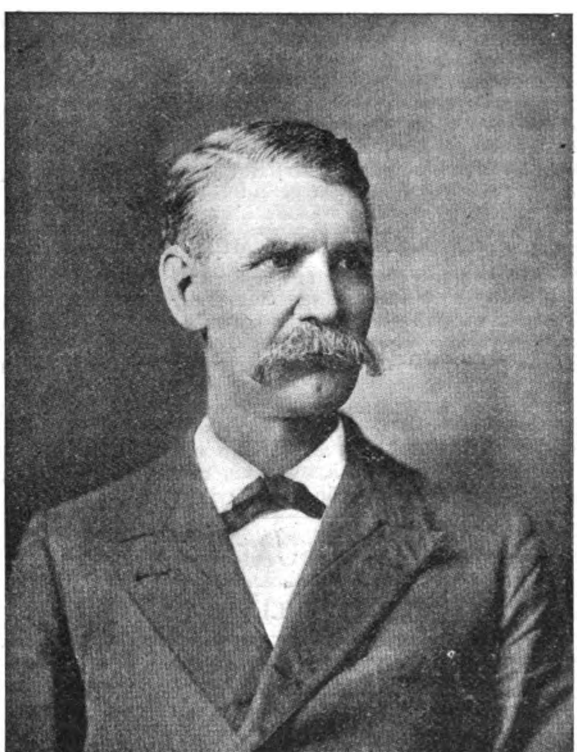
chandise brokers and factors and dealers in ores and metals of all kinds. Mr. Collins remained constantly engaged in this line of business until the summer of 1895, when he associated Mr. W. C. Temple with himself under the same firm name of H. E. Collins & Company, and took up the general introduction of the Cahall boilers. At the time of Mr. Collins' death this business had grown into one of great magnitude, the firm having branch offices in Boston, Philadelphia, New York, Detroit, Cleveland, Chicago, Cincinnati and New Orleans. The business will continue without any changes on the same lines followed in the past.

Mr. Collins was a prominent citizen of Pittsburg, being a trustee of the Homeopathic Hospital, trustee of the Shady Side Academy, an active worker in the matter of education, especially for the very young, and was always foremost in all beneficent or charitable enterprises organized in his city. Mr. Collins leaves a widow and five sons, the eldest being at present in Europe perfecting his musical education; the second son, Henry, is a student at the Naval Academy at Annapolis; the other three sons are living at home.

PERSONAL.

PRESIDENT ROBERT McCULLOCH,

THE new and highly esteemed president of the American Street Railway Association is of Scotch lineage, his ancestors having settled in Virginia in Colonial days, the paternal side in Amherst County and the maternal in Roanoke. The male members on both sides were soldiers of the Revolution. He is native of Rockbridge County, Va., and was educated at the Virginia Military Institute, at Lexington. He went as a cadet in the Confederate service, in April, 1861, and followed General Lee until his surrender in April, 1865. He established himself in St. Louis in 1869, and in 1871 entered the employ of the Bellefontaine Railway Company of that city



ROBERT McCULLOCH.

as superintendent, was afterward made secretary, and then vice-president and general manager of the company. He continued in that service until 1889, when Mr. D. G. Hamilton and his friends purchased the Citizens', St. Louis, Cass Avenue, Northern Central and Union lines, and he was made vice-president and general manager of these roads, which position he now occupies. At the age of twenty-six he married Miss Paxton, of Rockbridge County, Va., and his family consists of his wife, two daughters and a son, Richard McCulloch, who is the civil and electrical engineer of the roads named. His elder daughter, Roberta, is a student at Vassar College, and his Younger daughter, Grace, is receiving education in the public schools of St. Louis.

MR. WILLIAM H. CULL, superintendent of the Hudson River Telephone Company, who was compelled by reason of illness to temporarily leave Albany for treatment, has returned home. His host of friends will be pleased to learn that there is every prospect of his being speedily restored to perfect health.

SOCIETY AND CLUB NOTES.

THE NEW YORK ELECTRICAL SOCIETY.

On the evening of October 23, at Columbia College, the incoming president, Dr. Charles E. Emery, gave his inaugural address, entitled "Reminiscences of Forty Years of Engineering Experience."

He started out with a statement of the instruction received from a small toy engine when a boy, in which all the complicated movements of a link motion were derived by combining the motions of two cranks at right angles, thus developing at that time what has since been known as the Waelshart gear, used on the Continent and some steam vessels. He told of the efforts of Corliss and Wheelock to overcome the supposed inefficiency of the link motion by the use of special cut-off gear, which proved to be failures, as the link gives the early exhaust and cushioning required for the proper operation of a locomotive. He told of some experience with engines on naval steamers, of which the valve gear was designed by the late Lawyer Dickerson to secure unusual economies, which proved to be failures, referring to the dock trial which took place during the war and proved the old system best. He gave a statement of his early experiments with glass and iron cylinders, showing the loss due to cylinder condensation; discussed the advantages of compound and triple compound engines, and pointed out that it has of late been developed that the number of cylinders has been unwarrantedly increased in many cases, and that for pressures not exceeding 125 pounds fully as economical results can be obtained with a compound engine as with a triple compound engine.

Dr. Emery then gave some war reminiscences, calling attention to the fact that the vessels of the Mississippi squadron were painted with a pigment of river mud so as to be inconspicuous at night or in hazy weather; spoke of Porter concealing the topmasts of his bomb boats with green boughs to resemble the adjoining woods while bombarding the forts below New Orleans. He spoke of his connection with the accepted standard of boiler horse-power; of interesting experiences as judge of the Centennial Exhibition, including his being invited to act as assistant to Lord Kelvin, then Sir William Thomson, but which proved of little service to him on account of extra work caused by disorganization of his own group. He referred to some unwilling work done in superintending early elevators; gave a brief summary of interesting details of the work of the New York Steam Company, including expansion joints, meters, etc. He explained that the work was so exacting that he was obliged to relieve his mind during the evening in a different line, when he occupied himself in discovering the secrets of adjusting watches for position, the principles of which he briefly explained.

Dr. Emery then spoke of his connection with the improvements in terminal facilities of the New York and Brooklyn Bridge and of the valuable assistance that would be rendered by electric locomotives, but stated that contrary to his advice the best plans had not been adopted, in his opinion, for that particular location on account of local weakness of the bridge and the want of adhesion which would be experienced by the use of motors on a single car which should be sufficient to draw four cars on a 3 per cent. grade in sleety weather. He then stated some of the interesting problems he had investigated as an expert in matters relating to water supply, damage by floods, the financial problems arising from questions of replacing water power by steam power forever or for a long series of years, and closed with a brief reference to his experiments on electrical subjects and some interesting features of the tests of the large engine dynamos at the Chicago Exposition by a committee of judges, of which he was the chairman, and which resulted in the discovery at that time of the losses which have been particularly described recently by Mr. Blathy in various publications. The publication of the results of the Chicago experiments have been so long delayed for want of means by the Bureau of Awards that Dr. Emery stated he has in contemplation making a full abstract of the results for the information of the profession, perhaps in the form of a paper to the American Institute of Electrical Engineers, with-

out, however, referring to the particular exhibitors, and considering all the engines of equal efficiency and with the same friction.

MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The one hundred and ninth meeting of the institute was held on Wednesday evening, October 21, President Duncan in the chair, and one hundred members and guests present.

The meeting was devoted to a topical discussion of "Electric Traction Under Steam Railway Conditions." It was opened by Dr. Charles E. Emery. Communications were read from Charles K. Stearns and Charles H. Davis. The discussion was then taken up by Messrs. H. Ward Leonard, George S. Strong, A. E. Kennelly, C. F. Uebelacker, E. E. Ries, George L. Colgate and F. W. Darlington.

It is the intention to discuss the same subject at the Armour Institute, Chicago, October 28.

At a meeting of the Executive Committee, held in the afternoon, the following Associate Members were elected: Benoliel, Sol D., 1327 Broadway, residence, 120 West Thirty-fifth street, New York City; Fish, Milton L., Assistant Manager, Pasadena Electric Light and Power Company, Pasadena, Cala.; Rice, Arthur L., Professor of Steam and Electrical Engineering, Pratt Institute, Brooklyn, N. Y.

The following Associate Members were transferred to Membership: Herdman, Frank E., Mechanical and Electrical Engineer, Crane Elevator Company, Winnetka, Ill.; Gerry, M. H., Jr., Superintendent of Motive Power, The Metropolitan West Side Elevated Railroad Company, Chicago, Ill.; Hadaway, W. S., Jr., Electrical Heating Engineer, 107 Liberty street, New York City.

AMENDMENTS TO THE NATIONAL UNDERWRITERS' RULES.

Mr. C. M. Goddard, secretary of the Underwriters' National Electric Association, has just issued a notice announcing the annual meeting of the Electrical Committee of the association on December 8. The committee will be glad to receive suggestions regarding changes in or additions to the present rules, which those interested in the subject may wish to make. Blank forms will be furnished on application upon which the suggested changes can be drawn up, which will be submitted at the committee meeting. These blanks can be had by addressing the secretary of the association, at 55 Kilby street, Boston, and they should be filed not later than December 1.

NORTHERN ELECTRICAL ASSOCIATION.

The fifth annual convention of this association will be held in Milwaukee, commencing on January 20, to which all interested in electrical work are invited.

The secretary of the association has issued a blank circular of information containing a large number of questions, addressed to all electric lighting companies in the country. These, when returned, will be kept on file at the office of the association for the use of members.

ELECTRIC LIGHT MANAGERS IN OHIO.

The Ohio State Convention of Electric Light Managers has elected the following officers: President, John I. Beggs, of Cincinnati; vice-president, G. S. Long, of Troy; secretary-treasurer, Samuel Scovil, of Cleveland. The next annual meeting will be held in Cincinnati.

TELEGRAPH CELEBRATION IN BELGIUM.

The Belgian Administration of Posts and Telegraphs has been holding a celebration in Brussels, in honor of the jubilee of the telegraph service. There were many interesting features. A large picture was exhibited in the central hall of the Telegraph and Posts building, representing S. F. B. Morse, with a paper tape in his hand containing the famous first message: "What hath God wrought," and resting his hand on a telegraphic globe.

THE DESIGN OF LARGE ARC DYNAMOS.

REFERRING to the description of the design of large arc and composite dynamos by Mr. George Albers in our issue of Oct. 7, Prof. Elihu Thomson has favored us with the following comments:

"The article on the design of large arc dynamos by Mr. Albers deals with a question to which I have given considerable thought.

"Mr. Albers proposes to revolve brushes in contact with incomplete rings in his arrangement. I should not think this was as good as revolving the segments and leaving the brushes stationary, where they can be attended to or adjusted if necessary. The machine which he proposes I should think would, also, in case any little trouble happened to the commutating arrangements, have to be shut down, and precisely the same purpose, I think, could be fulfilled by changing the arrangement so as to keep the brushes stationary and revolving the contact segments, as in almost all apparatus of this kind these two things are interchangeable in their relations.

"I have not had time to study into the merits or demerits of the machine in detail, but I will simply say that I agree with Mr. Albers in the general idea that a large machine having several circuits is desirable, and that a machine with stationary armature coils gives, as I pointed out in my patent, the ability to regulate in a variety of ways. In fact, Mr. Albers speaks of these ways in connection with the type of machine which he proposes. He speaks of the use of choke coils or constant current transformers. These are the precise devices which I have shown in my patent as applicable to the case in question. I do not think that the regulation for arc light loads could be effected by putting opposite sides of the dynamo in parallel through a commutator, as that would change the character of the machine. Perhaps Mr. Albers does not mean that this shall apply to arc light work.

"The question of combining in one large generator, directly connected to the engine, a number of separate dynamos, which may be used for arc lighting or for other work, was presented to my mind many years ago, and I worked out the type which is described in my patent No. 538,406, as one which met most completely the practical conditions, inasmuch as the commutators might be replaced even while the machine is running, and indeed sections of the machine itself removed for repairs without disturbing the working of the other parts."

LETTERS TO THE EDITOR.

ELECTRIC RAILWAY PROBLEMS.

Your editorial in the current issue on "Electric Railway Problems" states many facts which are universally conceded by unprejudiced engineers. Your belief "that a one-motor equipment can be produced that will do all and more than the present two-motor arrangement" bids fair to be soon realized. I am at present constructing a horseless carriage on the plans of my hydraulic system of street car gearing which has already been described in the Engineer, and present indications are that it will fully demonstrate the practicability of such a system, and such being the case it will readily be seen that it will fulfill all the requirements you mention, besides many others, the most important perhaps being the possibility of using the single phase alternating motor. HARRY E. DEY.

Pawtucket, R. I.

LEGAL NOTES.

GENERAL ELECTRIC vs. A SIEMENS-HALSKE PURCHASER, SETTLED OUT OF COURT.

In the United States Circuit Court at St. Louis on October 20 the complaints of the Edison Electric Light Company and the Thomson-Houston Electric Light Company against the Union Terminal Association were dismissed, the parties litigant having settled the matters in controversy outside of court, upon terms mutually satisfactory.

The suit is based upon the fact that about three years ago the Union Terminal Association purchased from the Siemens & Halske Electric Company an electric light plant for use in the Union Station in St. Louis. As soon as the plant was in successful operation the Edison Company and the Thomson-Houston Company brought suit against the Union Terminal Association alleging that the plant in use by the latter embodied various infringements of patents owned by the plaintiffs.

The settlement will not involve any expense to the Union Terminal Association, inasmuch as the manufacturers from whom the plant was purchased stand ready to make good any legal damages incurred by the use of their machinery.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED OCT. 13, 1896.

Alarms and Signals:—

SPEED INDICATING ALARM. Benj. F. Card, Brooklyn, N. Y., 569,171. Filed Aug. 31, 1895.
Means governed by the trolley independently of electrical energy for giving a signal at a predetermined speed of the car.

COIN-CONTROLLED SIGNAL APPARATUS. William Gray, Hartford, Conn., 569,195. Filed Sept. 7, 1895.
Details of construction.

BLOCK SIGNAL. L. C. Smith, Carbondale, Pa., 569,246. Filed July 9, 1895.
Comprises a series of locking devices operated simultaneously to lock the signal in the "danger" position upon the passage of a train, and means for unlocking the devices successively.

RAILWAY SIGNAL. J. Wayland, Newark, N. J., 569,263. Filed April 14, 1896.
Employs electromagnets operated by the passing of a train.

RAILWAY SIGNAL. James Wayland, Newark, N. J., 569,264. Filed April 14, 1896.
Consists of a supporting frame secured to the post, a semaphore rotatably mounted thereon, and a web on the frame overhanging the joint between the fixed and movable parts of the signal.

RAILWAY SIGNAL. J. Wayland, Newark, N. J., 569,265. Filed June 2, 1896.
Similar to above.

ELECTRIC TROLLEY RAILWAY SIGNAL. H. A. Parrish, Jackson, Mich., 569,424. Filed Oct. 23, 1895.
Means whereby the trolley wheels of the cars operate the circuit terminals to make and break the relay circuit to start and stop the signal.

BLOCK SIGNAL SYSTEM. J. E. Donbavand, Millville, N. J., 569,551. Filed Nov. 23, 1894.
The combination with a signal post, of the semaphore arm having a knife edge bearing thereon, a toothed segment connected with the arm to swing it to "danger," and operating mechanism geared to the segments.

Batteries, Primary:—

METHOD AND MEANS FOR ELECTRIC GENERATION. S. H. Short, Cleveland, O., 569,591. Filed April 9, 1896.
Consists in subjecting carbon to the electrochemical action of an electrolyte, capable of acting upon the carbon and regenerating the electrolyte through the agency of the negative plate.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. G. T. Woods, New York, 569,443. Filed Feb. 5, 1896.
Places in the circuit between the constant potential generator and the translating device a separately excited variable potential generator.

Dynamos and Motors:—

MAGNETO ELECTRIC GENERATOR. C. H. North, Cleveland, O., 569,385. Filed April 14, 1896.
Details of construction.

Electro-Metallurgy:

APPARATUS FOR MELTING METALS. E. G. G. Moldenke, Pittsburg, Pa., 569,221. Filed May 18, 1896.
Comprises a crucible furnace with sloping platform carbon electrodes inserted through the walls and a horseshoe magnet set between the electrode to blow the arc toward the charge.

Lamps and Appurtenances:—

SHADE HOLDER FOR INCANDESCENT LAMP SOCKETS. M. D. Greengard, St. Louis, Mo., 569,556. Filed Jan. 20, 1896.
Comprises a ring provided with circumferentially extended spring clasps and slides movable independently of them whereby they may move along both ring and clasp to operate the latter.

Miscellaneous:—

APPARATUS FOR DISINFECTING SHIPS OR OTHER STRUCTURES. H. R. Cassel, New York. 569,173. Filed June 29, 1894.
Consists in electrically producing a disinfecting fluid and a system of piping for distributing it in different parts of the ship.

ELECTROMAGNET. J. Wayland, Newark, N. J., 569,262. Filed Dec. 10, 1895.
Embodies an armature provided with wings to pass over two side polar faces, and a mass of iron connecting the wings to co-operate with the end polar face.

ELECTRIC HEATER. G. B. Fraley, Philadelphia, Pa., 569,278. Filed July 11, 1896.
Embodies a fireproof cylinder, coils of wire wound around the cylinder and a perforated metallic casing inclosing the same.

TIMING MECHANISM FOR RACES. C. A. Newbaker, Pittsburg, Pa., 569,296. Filed Feb. 25, 1896.
An electrically controlled clock mechanism adapted to be set in operation on the passage of the first horse across a predetermined line and to be stopped on the completion of the race.

PROCESS OF AND APPARATUS FOR PRODUCING CYANIDS. P. Danckwardt, New York, 569,325. Filed July 1, 1896.
Consists of melting the chlorid, introducing into the molten bath carbon and nitrogen, electrolyzing the bath while in contact with carbon and nitrogen, and continuously removing the cyanid so formed from the action of the electric current.

DENTAL CATAPHORIC APPARATUS. M. W. Hollingsworth, Philadelphia, Pa., 569,380. Filed June 29, 1896.
Comprises a yielding carrier adapted to be self-conforming to the surface with which contact is to be made. Intended for treatment of the teeth.

ELECTROTHERAPEUTIC BAND. B. H. Vellines, Norfolk, Va., 569,529. Filed Nov. 30, 1895.

Railways and Appliances:—

ELECTRIC BOND. M. J. Wightman, Scranton, Pa., 569,266. Filed Feb. 20, 1896.
Consists of a continuous plate of metal having upturned lips for union with the edge of a metal flange, and a bent intermediate portion, laid under the rail ends.

ELECTRIC RAILWAY. A. Gorton, Philadelphia, Pa., 569,331. Filed Dec. 31, 1890.
The conductor is placed in a longitudinal recess in the track and the current is taken by means of swinging brushes normally insulated from each other.

TROLLEY WIRE HANGER. W. S. Kisinger, Bantam, O., 569,338. Filed Feb. 8, 1896.
Consists of a yoke, an insulated member applied thereto, and having a vertical chamber with a pair of inclined bearings at its lower end, and a line wire holder provided with a pair of inclined lugs that engage over the bearings.

TROLLEY CATCHER. C. F. Randall, Denver, Colo., 569,352. Filed Feb. 11, 1895.
Comprises a casing, a two-part weight located therein, a spring held rod connecting the two parts of the weight, a dog hinged to the rod, a rachet located in suitable proximity to the weight, and a connection between the weight and the trolley pole.

ELECTRIC RAILWAY SYSTEM. B. R. Shover, Indianapolis, Ind. and E. P. Townsend, Asbury Park, N. J., 569,432. Filed Sept. 10, 1895.
Sectional conduit system.

Regulation:—

SYSTEM OF CONTROL FOR ELECTRIC MOTORS. E. A. Sperry, Cleveland, O., 569,305. Filed Feb. 21, 1895.
The combination of a main and auxiliary field coils, and means for connecting the auxiliary field coil to the main source of supply.

Switches, Cut-Outs, Etc:—

ELECTRIC SNAP SWITCH. C. G. Perkins, Hartford, Conn., 569,299. Filed July 31, 1896.
Means to permit the cover to be held positively in place by the handle.

ELECTRIC SWITCH. W. H. Powell, Hartford, Conn., 569,300. Filed Feb. 8, 1896.
A single pole switch

ELECTRIC SWITCH. W. H. Powell, Hartford, Conn., 569,301. Filed Feb. 8. 1896.
Similar to above.

ELECTRIC SWITCH. W. H. Powell, Hartford, Conn., 569,302. Filed June 29, 1896.
Comprises a base with a plural number of contact plates and brushes arranged in sets.

ELECTRIC SNAP SWITCH. G. B. Thomas, Hartford, Conn., 569,309. Filed May 16, 1896.
Employs a rotary block to make and break circuit.

SNAP SWITCH. G. W. Hart, Hartford, Conn., 569,332. Filed July 9, 1896.
Details of construction.

CUT-OUT FOR ELECTRIC CIRCUITS. L. W. Downes, Providence, R. I., 569,373. Filed July 23, 1896.
Consists of a fuse wire combined with an insulating sheath, and surrounded by a mass of finely divided refractory material in a loose condition, in such manner as to leave an air space about the fuse wire.

AUTOMATIC CUT-OUT FOR ELECTRICAL TRANSFORMERS. A. C. Booth, Cedar Rapids, Ia., 569,538. Filed Feb. 6, 1895.
Means for automatically cutting out transformers whenever they are not needed.

ELECTRIC SWITCH. G. Emmett, Attleborough, Mass., 569,576. Filed Feb. 26, 1896.
Especially adapted for cutting out arc lamps.

Telephones:—

ADJUSTABLE BRACKET FOR TRANSMITTERS. A. Y. Gordon, Massillon, O., 569,376. Filed July 21, 1896.
Comprises a plate having hinged thereto a bar provided with discs, heads pivotally connected to the bar, parallel bars connected to heads at the inner and outer ends, and the bar carrying the transmitter.

MULTIPLE STATION TELEPHONE CIRCUIT. J. A. Barrett, Rutland, Vt., 569,401. Filed Jan. 27, 1896.
Means for calling the substations selectively.

TELEPHONE EXCHANGE SYSTEM. P. E. Raverot and G. A. Hess, Paris, France, 569,470. Filed July 8, 1896.
Consists in a system of disposing and connecting the different devices constituting the switchboard.

NEWS AND NOTES.

THE STANDARD THERMAL UNIT.[1]

This report, read at recent B. A. meeting, advocates international discussion on the subject of a new thermal unit. It proposes to adopt the erg as the absolute primary standard of heat. As a secondary standard, of sometimes more convenient magnitude, an amount of heat equal to 4.2×10^7 ergs is suggested, and it is proposed to call this secondary unit the "Calory." As a method of defining this secondary unit, it is suggested that it might be specified as being one water-gramme-degree between 9.°5C. and 10.°5C., or, if this range of temperature is not consistent with a value of 42,000,000 ergs, then any other range of temperature of 1°C. as shall in future be determined to give a value of 42,000,000 ergs to the water-gramme-degree. This device has the advantage of fixing the value of the secondary unit independently of thermometry.

ARRESTED FOR SWEARING OVER THE TELEPHONE.

A novel arrest was made at Reading, Pa., on Oct. 13. Edward Hahl, a traveling salesman, called up the Union Transfer Company by telephone, and, it is alleged, used profane language to the lady clerk to hurry up the delivery of his baggage. He was arrested on a warrant, charging swearing, and committed in default of payment of fine.

[1] Abstract from the Report of the British Association Committee on Electrical Standards.

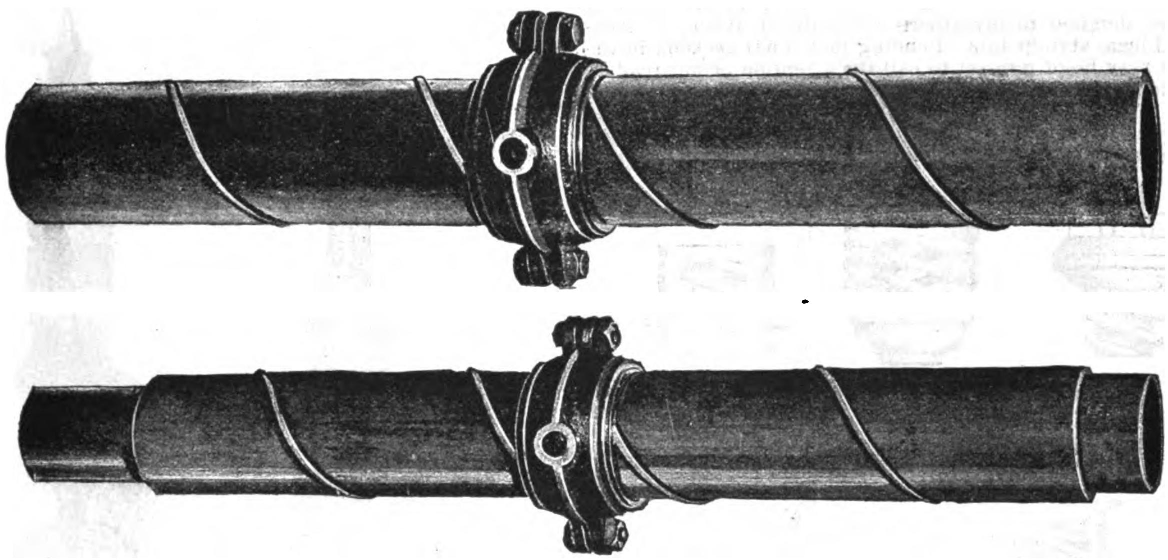
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

INSULATING SUBWAY CONDUITS OF THE INTERIOR CONDUIT AND INSULATION CO.

IN a handsomely printed catalogue just issued by the Interior Conduit and Insulation Company, we find an excellent illustrated description of that company's new system of insulating subway conduits, which presents several features of great novelty and utility.

The company has taken a bold stand by reversing the existing practice of placing main reliance upon the insulation of the wires and cables by so perfectly insulating the conduits themselves that the insulation of the wires becomes secondary and subordinate, such insulation, in fact, being only necessary where more than one wire is placed in a single duct, and then only for the purpose of insulating the wires from each other and not at all for the purpose of insulating them from the earth.



FIGS. 1 AND 2.—TYPES OF TUBING EMPLOYED IN NEW INSULATING SUBWAY CONDUIT.

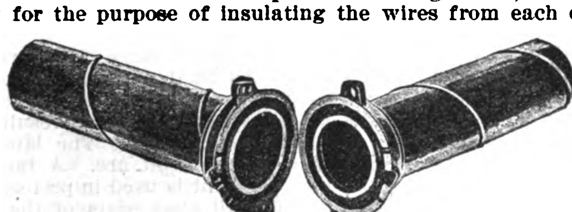


FIG. 3.—JOINT OF INSULATING CONDUIT.

By the use of this system it is claimed that not only are the wires fully preserved and protected, so far as insulation is concerned, but the lead covering now employed is rendered superfluous, the original cost and cost of handling of conductors largely reduced, and the bad effects of electrolysis are removed.

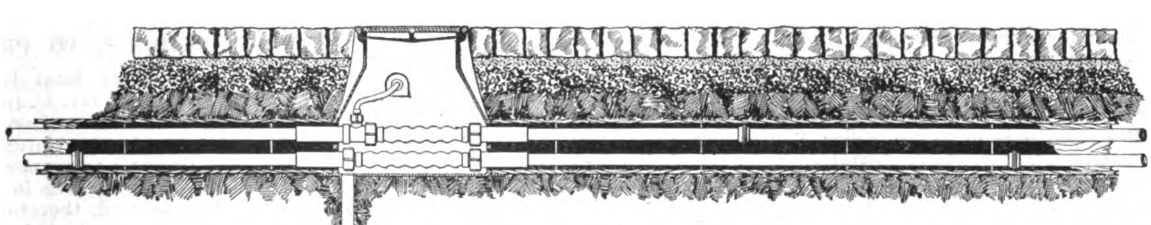

FIG. 4.—NEW INSULATING SUBWAY CONDUIT OF THE INTERIOR CONDUIT AND INSULATION CO.—SECTION.

The company, in fact, take the view that the correct principle is to have the insulation a part of the permanent and fixed equipment, and the copper as free and portable as is consistent with the nature of the work it is employed to do. If a single conductor, as, for instance, a railway feeder, it need have no insulation other than that afforded by its containing duct. If there be a series of conductors, they need but to be insulated each from the other.

In general, the system consists of a continuously insulated duct or raceway protected by heavy sheet iron armor, any number of the tubes thus formed being laid in a wooden trough or trench, and embedded in a plastic insulating compound for the further insulation and protection of the whole. The manholes are provided with especially devised means for continuing both the insulation and the protection across their area, while at the same time affording the convenient and effective access to each conductor, so essential in original installation and to the making of branch connections, as well as the periodic examinations of the conductors, which are so essential in all systems of wiring.

In order to meet the multifarious requirements of the several kinds of electric service, the varying conditions of soil and the diverse opinions of experts and practical men, the company manufacture tubes in a variety of types. Thus they make a simple tube of sheet iron of any desired weight and lined with their standerd asphalt treated insulating paper tubes, Fig. 1. For exceptionally high insulation, as where uninsulated wires are employed, this same tube is employed, but telescoped within it is an additional paper tube, the telescoping being done in such a manner as to prevent the joints or unions of the inner and outer tubes from becoming coincident. This yields, in effect, a continuous tube without joints, Fig. 2.

For feeder wires, or other service lines which are liable to become overheated and perhaps ultimately impair the insulation or imbed themselves in the insulation, so as to render their withdrawal in case of necessity extremely difficult, the company make a tube similar to that shown in Fig. 1, but with the addition of an inner lining of heavily coated sheet iron. In order to prevent the formation of a high static charge, and the consequent possible piercing of the insulation, these interior metal linings are made non-continuous by allowing a slight separation at each joint; this separation, however, is not sufficient to impair the utility of the lining for the purpose for which it is employed, but is ample for the purpose of overcoming electro-static effects.

The tubes are joined at their ends by cup-shaped locking collars having an annular chamber for the insertion of liquid insulating material through several openings. These collars or couplings are secured by locking bolts, as illustrated in Fig. 3.

To afford a simple and efficient means for insulating the conductors at manhole crossings, to effect a ready means for inter-

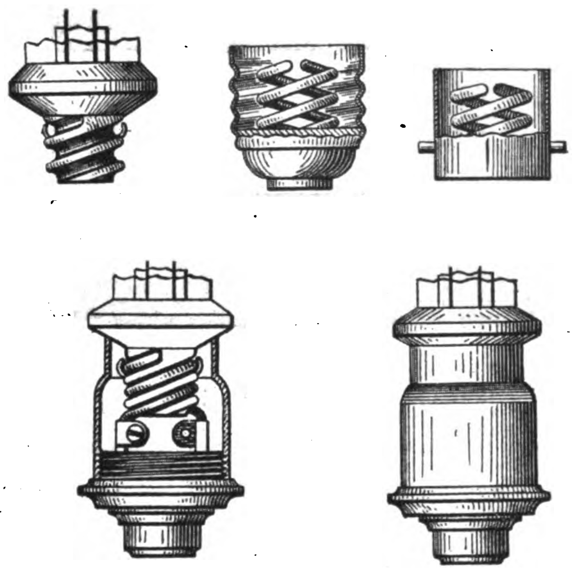
connection, and to give flexibility in the matter of size, construction, etc., for any desired number of ducts, the manhole illustrated in Fig. 4 has been designed for use in connection with their system.

The Interior Conduit and Insulator Company believe that this system presents the maximum advantages of insulation, permanency, convenience of handling, with a minimum of cost, both original and for maintenance.

CRIGGAL'S UNIVERSAL INCANDESCENT LAMP SOCKETS.

THE recent gathering of manufactui e: s and others inte ested in the adoption of a standard incandescent lamp base and socket, called together under the auspices of the National Electrical Light Association, is now awaiting the report of a committee detailed to investigate the subject, from the technical and legal standpoints. Pending their final decision in the matter it may be of interest to call the attention of our readers to a device of this nature, due to Mr. John Criggal, of Newark, N. J.

This consists of a lamp base made of a molded material, much resembling porcelain in its nature, and consisting of a



FIGS. 1 TO 5.—THE CRIGGAL UNIVERSAL INCANDESCENT LAMP SOCKET.

threaded portion, at the upper end of which the leading in wires are embedded, and whose ends protrude in the shape of small hooks, as shown in Fig. 1. Into this base there is screwed a socket, consisting of two spirals, Fig. 2, which represent the Edison lamp base; Fig. 3 shows another type, the Swan base; Figs. 4 and 5 show the base and socket when in position. As will be seen the spirals when screwed home engage the hooks forming the ends of the leading in wires, and thus make the desired contact. It will readily be seen that by this simple device any type of socket can be applied to the lamp base, and at a trifling cost.

THE STOREY MOTORS.

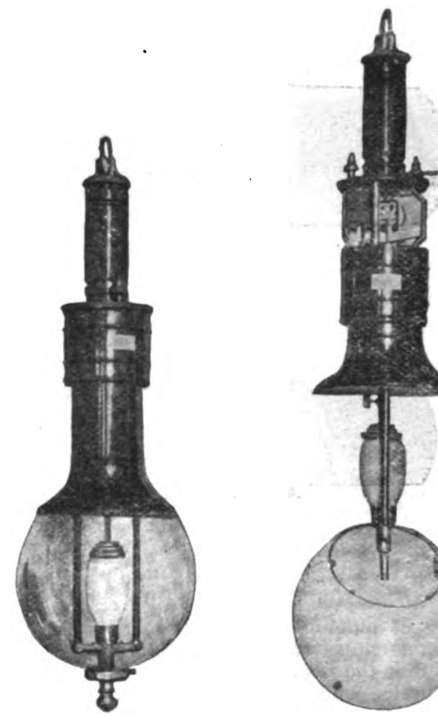
Mr. I. E. Storey, the president of the Storey Motor & Tool Company, Philadelphia, informs us that the concern has moved its main offices to 214-226 Carter street, below Chestnut, where, with greatly increased facilities, made necessary by the rapid growth of their business they will be able to execute promptly orders of any size. Mr. Storey regards the near outlook for his motors, etc., as very bright.

HAMMACHER, SCHLEMMER & CO.'S TOOL CATALOGUE.

The well konwn firm of Hammacher, Schlemmer & Co., 209 Bowery, New York City, have just issued a new and splendidly complete catalogue of their cabinet hardware, tools for all trades, specialties for electrical machinists, and a number of choice and meritorious novelties. Among the innumerable articles listed in this remarkably exhaustive catalogue, of interest to the electrical trade, are locks for telephone boxes, screws, wire nails, brass butts, piano wire of exceptionally high grade and temper, such as is particularly desirable in switch springs; files, saws, hammers, rules, tool chests and sets, vises, taps, screw plates, oilers, wrenches, etc. There is also a wide range of trimmings. The articles are profusely illustrated, scientifically grouped and classified, with prices, sizes, etc. Everything is strictly guaranteed. Firms and operating companies using goods of this class in the various electrical lines will certainly find it to their advantage to write Hammacher, Schlemmer & Co. and get a copy of this useful catalogue, which will be cheerfully sent on application, to any address.

THE "AJAX" ARC LAMP.

A NEW enclosed arc lamp that has already given a very good account of itself is the "Ajax," manufactured by Pomeroy, Woltmann & Co., 43 Cortlandt street, New York, which, it is claimed, will find favor with users of long life lamps. Among the special features of the "Ajax" lamp is the arc enclosing globe, which rests upon an air-tight ground



THE AJAX ENCLOSED ARC LAMP.

joint base, and for its cap has a series of three chambers, each successive one a little smaller and further removed from the arc, thereby greatly impeding the entrance of oxygen into the inner globe and causing a very steady light and resulting in but little combustion at the carbon points. The lamp consumes 4.7 amperes and carries an 80-volt arc. A rack rod, with a simple and positive escapement is used in preference to the clutch mode of feeding, and all steel parts of the movement are nickel plated to prevent rusting.

The outer globe holder is also a very simple and neat device, allowing the globe to swing entirely free from the lamp frame, and on this account and because the arc enclosing globe rests upon a ground joint base, it is claimed to be the easiest lamp on the market to trim.

Then, too, the shape of the inner globe is such that while the neck is large enough to admit of easy cleaning, the conformation insures an even distribution of the rays of light. The "Ajax" lamp is particularly adapted for large interior lighting.

NOT RAINBOW, BUT IRON BRIDGES, TO PROSPERITY.

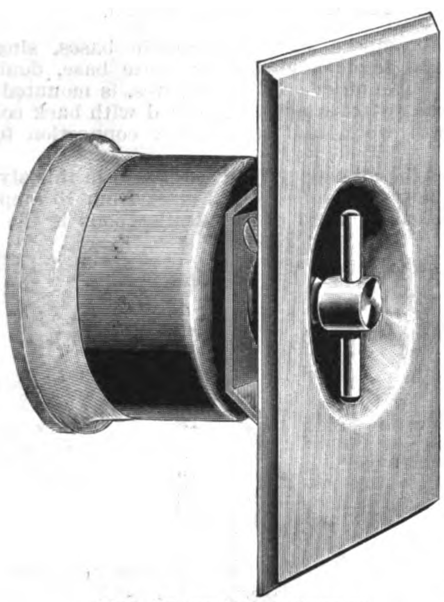
The Berlin Iron Bridge Company, of East Berlin, Conn., have received from their representative, Mr. C. Lerdo, Mexico, the contract for an iron market house at Guadalajara. If this market house were built anywhere in the United States and paid for in our own money, the contract price would be $5,615. The Berlin Company are, however, to receive in payment for this building Mexican silver dollars, and, therefore, their contract price with the city of Guadalajara is $11,230.

If the silver platform should prevail and there should be free coinage of silver on the basis of 16 to 1, what is to prevent the Berlin Iron Bridge Company from taking the dollars which they receive in payment on this building, each one of which contains more silver than the American dollar, take these to the United States mint and, free of expense, have them coined into American silver dollars? Under free silver they will then receive for their building 11,230 Bryan dollars, which, it is

claimed will be worth as much as gold dollars. Consequently they can be used in paying the employés, thus leaving the company a clear profit of over $5,000 on this one little transaction. Or, again, they can take these same 11,230 standard silver dollars and with these pay the labor and expense of building another market house, another bridge or building for the Mexican market, and receive for the same 22,460 Mexican dollars. They can then recoin these free of expense into American dollars, and thus by each transaction double their money. Does any laboring man in this country believe that labor paid for in money of that kind will have the purchasing power of our present dollar? Would there be any difference in paying labor in those dollars and reducing the present rate of wages 50 per cent.?

THE NEW PLATT FLUSH SWITCH.

IN addition to their New England switches, the O. S. Platt Manufacturing Company, Cannon street, Bridgeport, Conn., are now manufacturing what they regard as one of the strongest and best flush switches ever made, the design of Mr. Platt, who has always been so prolific in this field of engineering invention. The cut shows that the switch is self-



New Platt Flush Switch.

contained. Having a strong brass cap, it is not necessary for it to have an iron casing, as is the usual custom with flush switches. It is dustproof, has a swift, sharp snap, and when properly put up, is said to be absolutely without need of further atention. It is made in one size for ten amperes. The concern are also pushing their 500-volt New England switches for street railway use, and expect soon to have one or two other novelties on the market.

ACTIVITY OF THE ENGINEERING FIRM OF BRYAN & HUMPHREY, ST. LOUIS.

The firm of Bryan & Humphrey, consulting mechanical and electrical engineers, Suite H, Turner Building, St. Louis, has found business quite satisfactory during the past few months, in spite of the prevailing depression. It will be recalled that Mr. William H. Bryan, finding his work in mechanical engineering, especially in water-works, boiler and engine trials, steam heating and ventilating, growing to such proportions as to make additional expert assistance necessary, entered into a partnership last spring with Mr. H. H. Humphrey, with a view of having the latter take charge of the work in electrical engineering, and also to relieve Mr. Bryan somewhat in other professional work. That this combination is considered a good one is evident from the demand they are finding these dull times, for their services. They are now engaged upon, or have recently finished, work for the following well known firms:

Boiler and engine work: Laclede Car Company, John O'Brien Boiler Works Company, Herf & Frerichs Chemical Company, St. Louis Sanitary Company, Consumers' Brewing Company, Samuel Bowman & Co., owners, Fraternal Building, all of St. Louis; Edwardsville Electric Light and Power Company, Edwardsville, Ill.; L. Hoster Brewing Company, Columbus, O.

Water-works: City of Union, Mo.; City of Pacific, Mo.

Electrical work: City of Staunton, Ill.; City of Webster Groves, Mo.; A. Leschen & Sons' Rope Company, St. Louis Iron and Machine Works, Ely-Walker Dry Goods Company, Dozier Bakery, all of St. Louis.

Heating and ventilating: The new City Hall, the Y. M. C. A. Building, Missouri Medical College, W. E. Beckman, residence; L. D. Dozier, residence; the Hitchcock Building, all of St. Loius, and J. D. Gerlach, Chester, Ill.

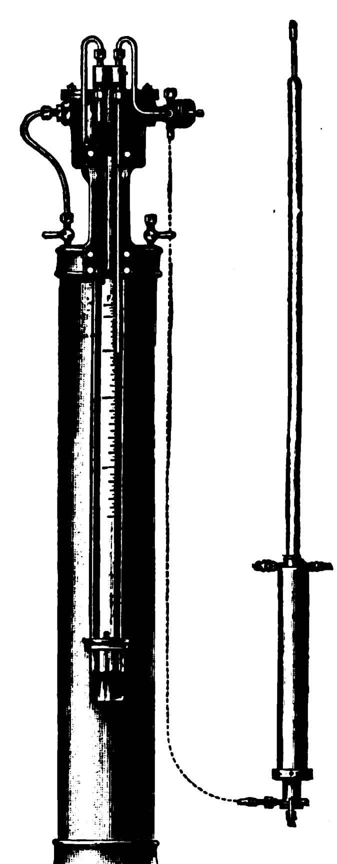
In addition to the above they have handled a great deal of less important work. They also have in hand the preliminary work for some important electric railway projects.

THE PNEUMATIC PYROMETER.

We illustrate in the accompanying engraving a novel form of instrument which is destined to become an important factor in all industrial operations where high heats are employed, and where the quality of the product depends largely upon the manner in which the temperature is applied and regulated.

This pneumatic pyrometer, manufactured by Uehling, Steinbart & Company, Limited, 62 Mulberry street, Newark, N. J., has proved itself accurate and reliable for temperatures up to and exceeding 3,000 degrees, Fahr. It is based upon the expansive properties of air employed in the following very unique but simple manner:

If two minute apertures form, respectively, the inlet and outlet of a chamber, and air be drawn through this chamber by a constant suction, then the tension in the chamber depends upon the difference of temperature of the air as it flows through the respective apertures. Hence if the inlet aperture be located in the space the temperature of which is to be measured and the outlet aperture is maintained at constant temperature, the tension between the two apertures will be a true measure of the temperature at which the air enters the inlet aperture, and consequently of the space in which it is located. This instrument not only indicates the temperature accurately and continuously, but it does it at a distance, and at several places



The Pneumatic Pyrometer.

at the same time if desired, and makes an autographic record of the same. It shows continuously what is happening at the time, and also what has happened within its province at any time previous. This instrument has already found great favor among the manufacturers of iron and steel.

Its use in electrical work is also generally applicable, as, for

example, in the baking of incandescent lamp filaments, electric furnaces, etc. It can also be employed to give a continuous record of the temperature in boiler furnaces, and thus acts as a continuous check on the work of the fireman.

The instrument is substantially and accurately made, and the principle of its construction makes it practically impossible to get out of order.

A BROADSIDE OF SEARCHLIGHTS.

One of the most enthusiastic of the electrical goldbugs is Mr. S. W. Rushmore, of the Rushmore Dynamo Works, Jersey City, N. J., and he showed his patriotism by making a grand display of searchlights in connection with the Sound Money marine parade of the New York shipping, which took place on the night of Oct. 24. Besides having over a dozen powerful lights on vessels in the parade, there were erected on the roof of the seven-story Rushmore factory, which is opposite Cortlandt street, New York, a solid line of fifteen 40-ampere projectors of the latest type and being on the water front and over 125 feet above the water, they commanded every point in the city and harbor.

These lights were operated by skilled attendants who had been drilled to work them together to produce some beautiful effects and the spectacle as viewed from New York was exceedingly impressive. Power was supplied by a 250 h. p. Corliss engine driving a 110-volt Rushmore generator, which by day furnishes the power for the various departments of the works.

The same apparatus will be used on election night and has been engaged by a New York newspaper to announce the result of the election by flashes on the sky, which will be seen for miles in all directions.

BIDS WANTED FOR ELECTRIC LIGHT PLANT IN THE NEW YORK POST OFFICE.

The Theasury Department, through W. E. Curtis, acting secretary, is inviting proposals until November 9, for installing an electric light and power plant in the Court House and Post Office Building in New York City.

Proposals will be received, first, for wiring building; second, for dynamos and engines; third, for boilers and connections; fourth, for the plant complete; fifth, for the removal and purchase of eight boilers now in the building.

Prospective bidders may obtain additional information and particulars by addressing Hon. W. E. Curtis, acting secretary of the Treasury, Washington. D. C.

STREET LIGHTING WITH INCANDESCENTS IN ST. LOUIS.

Incandescent electric lamps will be used in lighting the streets, alleys and public places in St. Louis under the contract authorized by the ordinance which passed the Municipal Assembly just before the summer recess began. The specifications adopted by the Board of Public Improvements contain a provision to this effect, and say that the lamps shall be of 32 c. p. By the terms of the ordinance the board is directed to solicit bids for lighting that part of the city lying north of Keokuk street for a term of twenty years from January 1, 1900, and the remainder of the city from February 17, 1905, to December 31, 1919, the new contract to begin at the expiration of those now existing. The specifications provide for a single letting of the contract. No day has yet been set for beginning the advertisement for bids. The letting will be held after ninety days' advertising. It is estimated that on January 1, 1900, when the new contract begins, 25,000 lights will be needed in the territory north of Keokuk street. Payment is to be made at a rate to be named for each 1,000 lamp hours.

SUNBEAM INCANDESCENT LAMP CO.

The Sunbeam Incandescent Lamp Company, Chicago, has completed and is now operating its new factory at Desplaines, Ill., just outside of Chicago limits. In every department, new and special apparatus has been added with the view of improving the product. Although the new factory is very much larger than the old one, it has already been found necessary to operate it at its full capacity, so as to keep up with the large number of orders that are being received. That it may have selling facilities in keeping with its new manufacturing plant the Sunbeam Company has arranged to market its entire output of lamps through the Western Electric Company, Chicago. Its sales department will be removed to the Western Electric Company's building, No. 242 South Jefferson street, and this arrangement will give the Sunbeam Company an excellent selling organization.

THE JONES SWITCHES.

We illustrate in the accompanying engravings two styles of switches manufactured by J. Jones & Son, 67 Cortlandt street, New York.

Fig. 1 shows their standard "Baby" style; this is made in

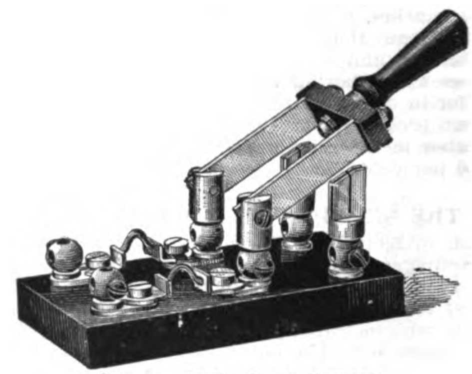


FIG. 1.—JONES BABY SWITCH.

smaller, or 25 ampere size on porcelain bases, single pole, double pole and triple pole, and on slate base, double pole, double throw. The other size, 35 amperes, is mounted on slate entirely. These switches are also carried with back connection for switchboard work, and with screw connection for panel boards.

Fig. 2 shows the all copper type, the bases in this style being slate only. They are carried in all sizes from 15 amperes up.

The workmanship on all of the firm's goods is the highest.

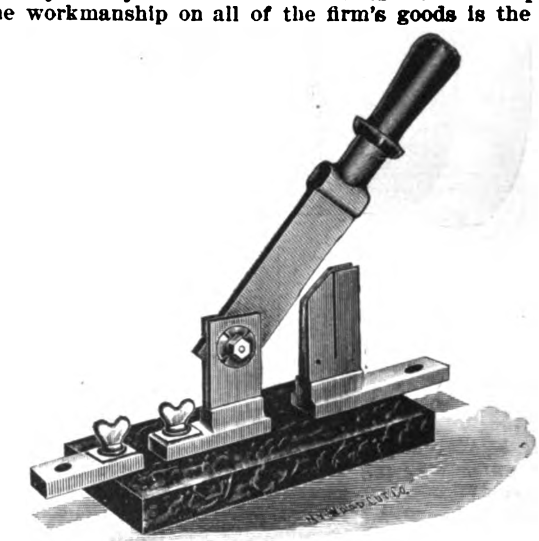

FIG. 2.—JONES ALL COPPER SWITCH.

The working parts are fitted to act to a nicety and the contact surfaces are made to make the proper bearings. One feature in the switch worth mention is the ability to adjust the friction of the blade between the leaves of the back post. One side of the back post is threaded, so that the screw going blade may be loosened or tightened between the two leaves and an adjustment obtained not to be found on any other switch.

OF INTEREST TO BUYERS.

WILKINSON MANUFACTURING COMPANY, Bridgeport, Montgomery County, Pa., manufacture one of the best mechanical stokers in the market, adapted to all forms of steam generative furnaces, kilns, etc. Its mechanism insures uniform thickness of fire, ample air supply for any rate of combustion. There are no clinkers. The operation throughout is easily managed. Catalogues are mailed on application.

GOLDMARK & WALLACE, 29 Chambers street, New York, are selling agents for the United States of the Koch woven wire tube dynamo brush.

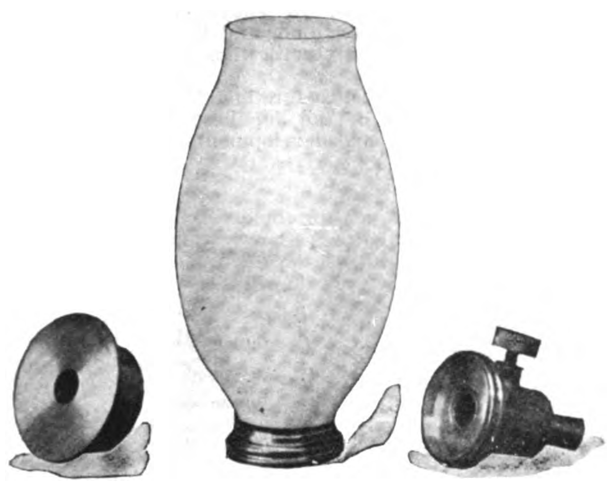
CHARLES N. MARTIN, silk manufacturer, 348 Canal street, New York, carries a full line of silk for insulating purposes.

PERU ELECTRIC MANUFACTURING COMPANY, Peru, Ind., manufacture a full line of porcelain insulation for electrical purposes, knobs, cleats, motor cut-outs, tubes, main and branch cut-outs, rosettes, switches, etc., and manufacture to order any porcelain specialty desired. They are makers of the Laclede and Hercules Batteries.

THE PIONEER LAMP GAS-CHECK PLUG.

A special feature of the "Pioneer" inclosed arc lamp is the gas-check plug. This plug, illustrated in the accompanying engraving, consists of two parts so arranged as to form a chamber to which the gases of the arc have access. The plug is inserted in the upper end of the small inclosing bulb and closes the bulb against the ingress of air. A small amount of oxygen is, however, allowed to reach the arc so as to combine chemically with the volatilized carbon. Thus it will be seen that the "Pioneer" lamp has a double chamber for the gases formed by the arc, this double chamber consisting of the small bulb and gas-check chambered plug; in addition to these a large outer globe is also used.

This gas-check plug or "dead-air" chamber performs a most valuable function in the lamp. It permits the use of a small carbon at a very high efficiency, and reduces the amount of carbon consumption to a minimum; besides it permits of the continuous efficient operation of the lamp at the very smallest possible current. Hence it is that the "Pioneer" lamp gives more life for the amount of carbon consumed than any other lamp on the market and at the same time gives a light efficiency from 25 to 30 per cent. greater than is possible without the use of the "dead-air" chamber.



Gas-check Plug; (fits in mouth of Bulb). Enclosing Bulb; (surrounds the Carbons). Lower Carbon Holder; (supports the Bulb).

THE PIONEER ENCLOSED ARC GAS-CHECK PLUG.

One of the greatest objections to the inclosed arc is the falling off in candle-power toward the end of the run. In the "Pioneer" lamp this is practically overcome, the difference in the amount of light between the beginning and the end of a run of a pair of 7/16 inch carbons in this lamp not being noticeable.

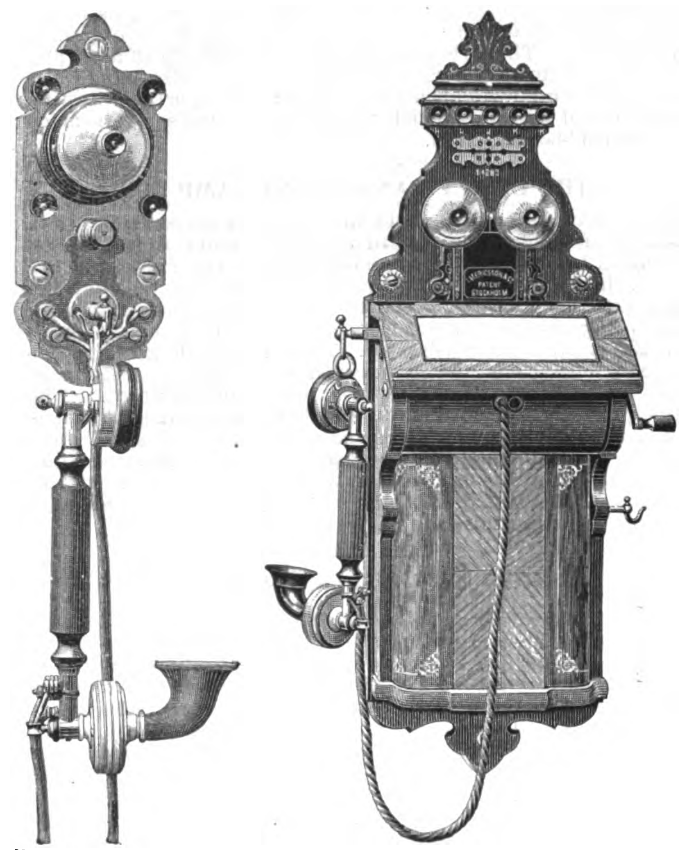
The gas-check plug of the "Pioneer" lamp is designed not only to act as a secondary gas chamber which retards the access of oxygen to the arc, but also to serve as a movable closure to the bulb, whereby the lamp operates just as well with a moderately crooked carbon as with a straight one. The simplicity of the lamp is such that little or no electrical skill is required to handle it; in fact, in many stores throughout the country "Pioneer" lamps are trimmed by clerks who have no knowledge of electricity.

SPRAGUE ELECTRIC ELEVATORS IN THE SIEGEL-COOPER BUILDING, NEW YORK.

Perhaps the most striking example yet afforded of the fact that the electric elevator has come to stay for all classes of work for which an elevator can be employed, is that presented by the elevator installation in The Siegel-Cooper Company's "Big Store" in New York. Reference has already been made in our columns to this installation, but it may be interesting to recall that the twenty-one Sprague electric elevators are now in daily operation, carrying passengers, employés, freight and packages to the various departments from the cellar to the six floors of the great building. The elevators installed are of the single and double-drum form gear type, according to the various uses to which they are applied. Each is equipped with the Sprague regulator and safety devices and their success has been most marked in every way, so much so that two more have recently been contracted for, which will be put in operation shortly, making in all twenty-three.

ERICSSON SWEDISH TELEPHONES.

It is now about three years ago that Messrs. Smith & Patterson, of No. 256 Broadway, began to introduce the celebrated Ericsson Swedish telephones. These instruments had already made for themselves a European reputation, no less than 300,000 of them being now in use in Norway, Sweden, France and Germany, and only recently they have been adopted by the Japanese Government. Since their introduction in this country they have been installed for interior work by no less than 200 firms in all kinds of situations. Thus on the banks of the Mississippi, where the dampness seems to affect most telephone transmitters those of the Ericsson type have worked without the least trouble for several years past.



FIGS. 1 AND 2.—THE ERICSSON SWEDISH LONG DISTANCE AND INTERIOR WALL SETS.

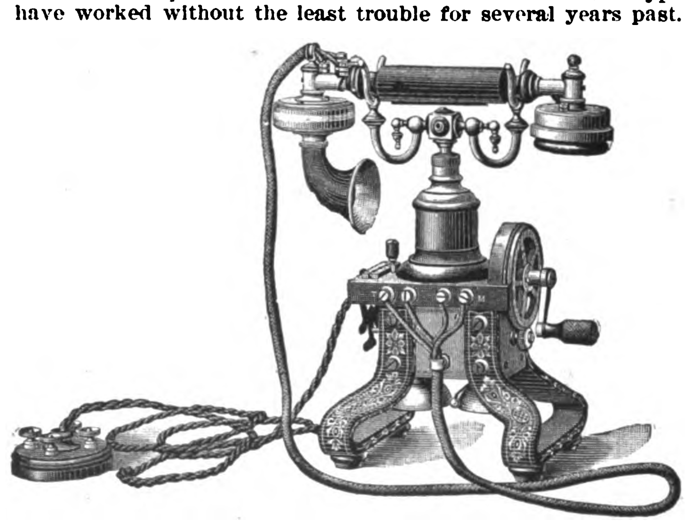


FIG. 3.—THE ERICSSON SWEDISH TELEPHONE DESK SET.

We illustrate in the accompanying engravings a number of different styles in which the Ericsson transmitter is arranged for the various characters of service.

Fig. 1 shows the instrument specially adapted for interior work. This is a battery call set, with vibrating bell, etc. As

will be seen the microphone is attached to the bar carrying the receiver; thus one hand suffices to carry the transmitter to the mouth as well as the receiver to the ear, leaving the other hand free for the recording of memoranda. This wall set is also made with the transmitter directly attached to the board.

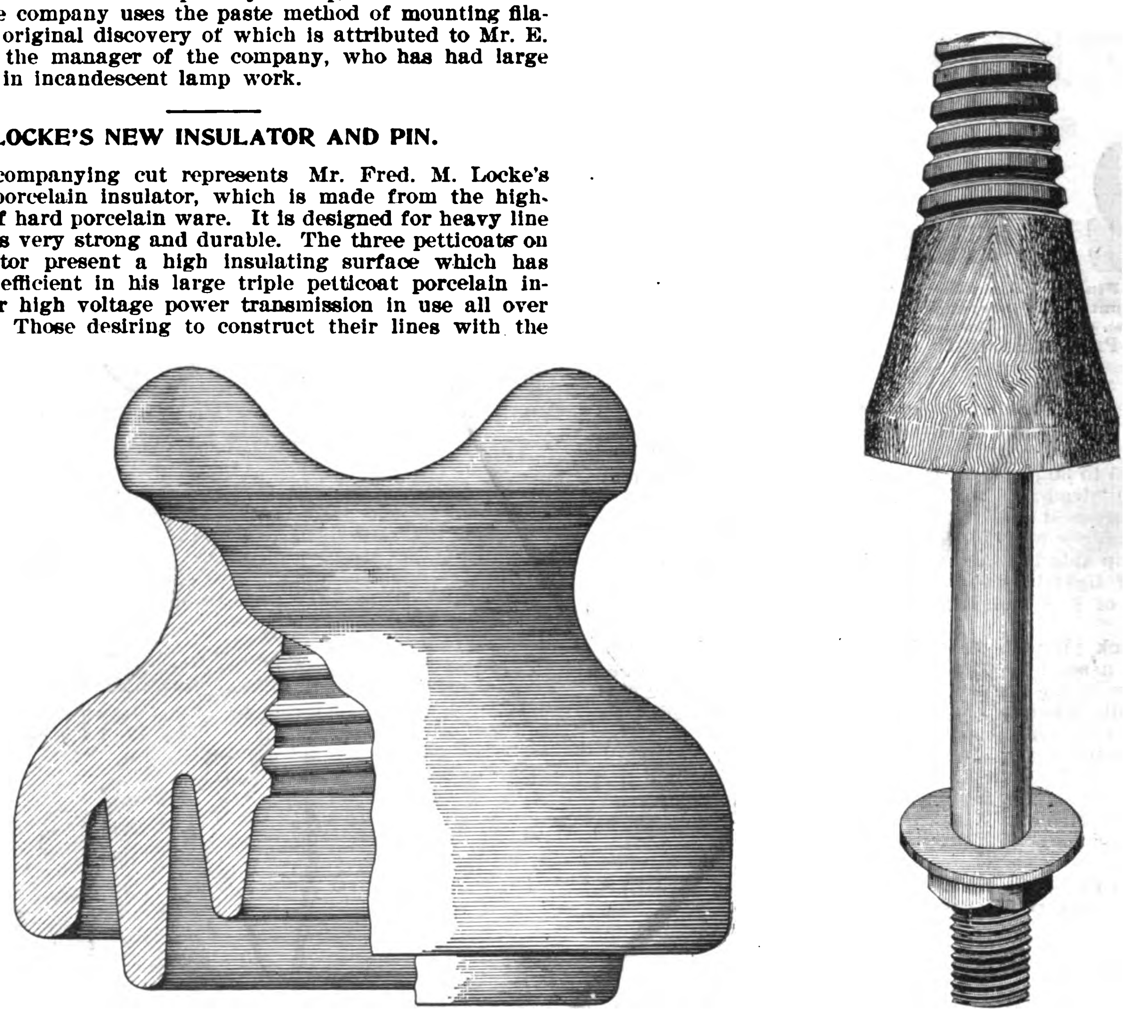
Fig. 2 shows a wall set specially constructed for long distance work. This was adopted by the Russian Government for use on its long distance lines. Fig. 3 illustrates the Ericsson Swedish desk set. This is a complete instrument, with magneto-generator and bells and rings through 25,000 ohms resistance. The instrument is highly finished and is an ornament to any office. The Ericsson telephone is made up in a variety of special forms. Messrs. Smith & Patterson also handle the Ericsson small switchboards, receivers and portable testing sets, as well as the Swedish telephone lineman's plyers made of "electro"-boracic steel.

THE LYNN INCANDESCENT LAMP CO.

The Lynn Incandescent Lamp Company have equipped a factory in Lynn, Mass., with special machinery for the renewal of burned out incandescent lamps. The subject is one which has attracted considerable attention in the lighting field and the progress of the Lynn Company has resulted in their being able to turn out first-class lamps at a cost much below the original purchase price. The lamps undergo forty-two different operations and six inspections from their receipt at the factory to the time they are ready for shipment. The utmost care is paid to them in all the various stages, and it is believed that the same lamps may be repaired almost indefinitely. The company uses the paste method of mounting filaments, the original discovery of which is attributed to Mr. E. T. Dwyer, the manager of the company, who has had large experience in incandescent lamp work.

LOCKE'S NEW INSULATOR AND PIN.

THE accompanying cut represents Mr. Fred. M. Locke's new porcelain insulator, which is made from the highest grade of hard porcelain ware. It is designed for heavy line work and is very strong and durable. The three petticoats on this insulator present a high insulating surface which has proved so efficient in his large triple petticoat porcelain insulators for high voltage power transmission in use all over the world. Those desiring to construct their lines with the highest insulation accompanied with strength and safety should secure them for their lines. The insulator is shown full size.



Locke Petticoat Insulator and Pin.

We illustrate also the new Locke steel pin, two-thirds real size. This pin has been designed for heavy work in combination with the strong porcelain insulator just shown. Its introduction will be greatly appreciated as such an article has been needed. These specialties are being made by Mr. Locke, at his factory, Victor, N. Y.

THE WELLMAN DUPLEX ELECTRIC ELEVATORS.

We were favored last week with a call from Mr. H. E. Heller, representing the Armitage-Herschell Company, of Buffalo, manufacturers of the new Wellman duplex electric elevators, for which Heller, Wellman & Curtiss, electrical engineers and contractors, of Buffalo, N. Y., are sole agents. This elevator, the invention of Mr. H. Robinson Wellman, embodies a differential gear with a novel application of electric principles. It is claimed that the motor is brought up to speed without an excessive rush of current in starting, and that through the leverage developed the load is gradually accelerated through a predetermined space of time. Cards showing the results of actual tests would seem to indicate a high efficiency for the Wellman elevator.

CIRCUIT BREAKERS IN JAPAN.

The immense strides which the Japanese are making in sciences and liberal arts is in nothing better shown than in its electrical development. In Tokyo electric lighting is the rule rather than the exception, and light and power stations there compare favorably with those of New York and Philadelphia.

There was in this city week before last Mr. Seiryo Mine, the accredited representative of the Japanese Government, sent to this country to study recent developments and improvements in the use of electrical appliances, and more particularly, the use of safety devices in connection therewith.

From New York Mr. Mine went to Philadelphia, where he visited the Baldwin Locomotive Works, the Pennsylvania Railroad, the plant of the Light, Heat and Power Company, and the Cutter Electrical & Manufacturing Company, whose circuit breakers or electric cut-outs have eliminated one of the chief dangers to the users of heavy electrical currents, that of fire and destruction to electrical apparatus. The interesting plant

of the Storage Battery Company and the great power station of the Union Traction Company were not forgotten, but it was with the Cutter Company that Mr. Mine spent most of his time, and expressed himself as being delighted with the mechanical and electrical skill as there shown in the development of this important device. The best part of two days was spent in this study, and the importance of some of the tests made would have been apparent even to one not as well versed in electrical matters as is this representative of the Mikado. Mr. Mine will return to Japan after visiting the Street Railway Convention now being held in St. Louis, and will take back with him a thorough knowledge of the particular branch of the electrical science which he was sent here to study.

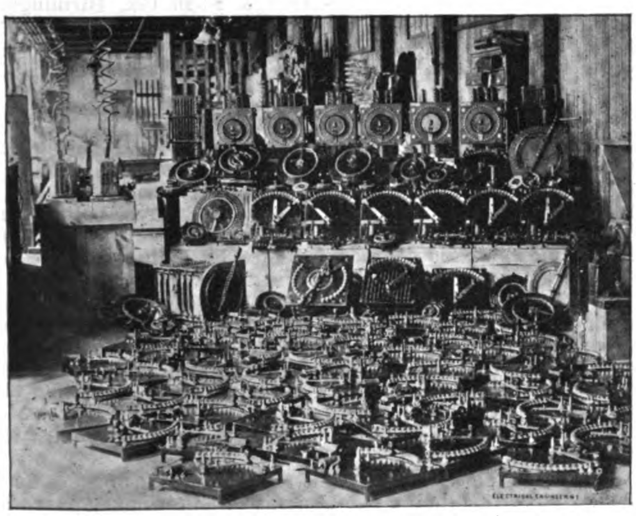
The fact that the Cutter Electrical & Manufacturing Company have already made several large shipments of their circuit breakers to Japan, reflects as favorably upon the progressive character of the Japanese as upon the energy necessary to introduce such devices in the far distant East.

When one realizes that the Japanese Government has in the Bank of England one hundred and fifty millions of dollars of gold and an equal amount of silver bullion, and that it is the intention of the government to spend this sum in furthering its mechanical, industrial and electrical enterprises, one begins to realize the position which these Yankees of the East will occupy at no distant date. In the mean time there is a field there which is well worthy of consideration by our manufacturers of electrical apparatus.

WARD LEONARD AUTOMATIC RHEOSTATS.

The Fire Department of New York and many other large cities have recently adopted rules as to automatic rheostats which are of importance to all parties using electric power.

The rules of the Fire Department of New York City, which went into effect last month, state: "Motors exceeding 1 h. p. must be protected by both fusible and magnetic circuit breakers, of which one at least must be double pole. The magnetic cut-out or switch must be so designed and adjusted that it will automatically cut off current from the motor whenever the supplying current is interrupted; both cut-outs shall operate



Leonard Automatic Rheostats.

automatically to cut off the current whenever its flow shall exceed, for one minute, the normal requirements of the motor by more than 30 per cent."

To meet the demand occasioned by this rule several manufacturers are offering automatic rheostats which have the double protection called for by the rule, namely, excessive current and failure of current.

The Ward Leonard Electric Company who have been selling such rheostats for about a year past report that for some time past they have been supplying these rheostats to European customers, who seemed to appreciate the importance of these desirable protective features more quickly than customers in this country.

We show on this page a group of these rheostats comprising part of a shipment to a single customer of the Ward Leonard Electric Company in Germany.

It seems odd that the German market should first show a vigorous demand for a device brought out in the United States, and this would seem to show that the Germans are keeping very close watch of progress in electrical lines in this country.

We learn that Mr. S. Bergmann, who has very extensive electrical manufacturing interests in Berlin, has recently secured from the Ward Leonard Electric Company the sole right to represent them in the sale of their goods in Germany, Austria, Russia, Belgium, Denmark and Sweden.

WESTINGHOUSE ENGINES ABROAD.

An order which the Westinghouse Machine Company recently received through its Paris branch for a 1,200 horse-power engine similar to those exhibited by that company at the World's Fair, would seem to indicate that some features of the great Exposition made substantial and lasting impressions on our foreign visitors. The engine is to be used in an electric lighting station in France.

THOMAS & HUNTER.

A firm of electrical contractors who have been in existence since only the first of this year are Thomas & Hunter, of Richmond, Va. The firm is composed of Maurice W. Thomas and Maurice Hunter, both of whom were connected with the Old Dominion Electrical Construction Company, of Richmond, until just before that company went into the hands of a receiver. Mr. Thomas was the traveling manager for this company, while Mr. Hunter was the engineer.

The new firm have already secured a number of good contracts, the most recent being the one for the wiring of the new buildings of the University of Virginia, for 3,000 lights in Armorite iron conduit. Another of their contracts is one for a municipal plant at Washington, N. C., for which they will be ready presently to receive bids on an automatic high speed safety engine of 150 horse-power, an alternating incandescent dynamo of 1,200 16 candle-power lights, and an arc dynamo of 50, 1,200 candle-power lights and two 85 horse-power return tubular boilers.

OSBURN ELECTRIC SUPPLY CO.

The Osburn Electric Supply Co., 294 and 296 Dearborn street, Chicago, have taken the agency of the "Crown" woven wire dynamo brushes, made by the Crown Woven Wire Brush Co., of Salem, Mass. They will carry a complete stock of the Crown, Crown "K," and Crown Alloy brushes, which will be the largest stock carried in the West. These woven wire brushes are becoming very popular with the trade, and the company are making a specialty of the brush business, being prepared to supply any style, size or shape in woven wire brushes of copper, brass or alloys. In congratulating the Osburn Electric Supply Co. on obtaining this agency, we feel that they will create a large demand for these goods in their territory.

NEW YORK NOTES.

THE PHILLIPS INSULATED WIRE COMPANY have given up their New York office and all business in future will be conducted direct from their general office and factory, at Pawtucket, R. I. The officers of this company are H. C. Adams, president; H. O. Phillips, treasurer and general manager, and H. C. Adams, Jr., secretary.

J. JONES & SON, 67 Cortlandt street, this city, have just issued a choice new catalogue, large octavo, 186 pages, devoted to electric lighting supplies and specialties, and embracing a great many things made exclusively by them. The supplies range from lamps to construction material, and the display is remarkably comprehensive. The concern will shortly issue a companion catalogue of their bell, gas lighting, telegraph, telephone and house supplies.

THE BALL & WOOD COMPANY is taking advantage of ante-election quiet in business to improve its shop equipment at Elizabeth, N. J. This company has recently reorganized the nickel plating department of its works and added quite an extension to one of its buildings for its accommodation. A new tool room has also been organized and equipped and every preparation made for an anticipated revival in business after November 3.

A. K. WARREN & CO. have permanently located themselves at 451 and 453 Greenwich street, in the Trinity Building, opposite their temporary premises in Desbrosses street, in the shops lately occupied by the Garvin Machine Company. Messrs. A. K. Warren and James Rich Steers, the proprietors, have secured in these premises greater facilities for handling their peculiar business, as the shop, store and offices are all on one large ground floor, greatly facilitating the handling of heavy machinery, which, in repair, constitutes the main part of their business. Their contract department for maintaining electric plants has met with such success that they have had to engage further experienced help to keep up with the demand for inspections. A visit to their stores will repay all users of electrical machinery, as it will familiarize them

with their complete system of handling emergency or breakdown work, which is now reduced to a science. Their telephone, 881 Franklin, is open night and day for calls on this class of work.

ADVERTISERS' HINTS.

THE WESTERN ELECTRIC COMPANY are now the New York agents for the "O. K." line and house wires made by the Phillips Insulated Wire Company of Pawtucket, R. I.

THE BERLIN IRON BRIDGE COMPANY show in their "ad." this week a cut of an iron water tower built by them for the Newport News Waterworks.

THE LYNN INCANDESCENT LAMP COMPANY, Lynn, Mass., renew lamps at twelve cents and pay the freight charges.

THE H. P. BALL MANUFACTURING COMPANY, 101 Beekman street, New York, manufacture switches and switchboards for all purposes and devote special attention to street railway orders. They also make theater dimmers, rheostats, distributing boards, etc., and are glad to submit estimates on all classes of work.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY state that there are now 9,000 of their arc lamps in service.

GREENE & DIKEMAN, 14 Cortlandt street, New York, offer "Ward" and "Knight" arc lamps at $9.50. They also advertise a new 150-hour lamp, brass finish, at $26.

E. H. KELLOGG & COMPANY, 243 South street, New York, supply oils for railways, dynamos, ice machines, engines, and, in fact, for all purposes where a lubricant is required.

THE ELECTRIC APPLIANCE COMPANY are the Western agents for the "Electra" Nurenberg Carbons, of which Hugo Reisinger, 38 Beaver street, New York, is the importer. They report that the excellence of this brand of carbons has made them very popular and the demand for them is steadily growing.

THE SAFETY INSULATED WIRE AND CABLE COMpany furnished all the insulated cables for the transmission of Niagara power to Buffalo. They were specified to test 20,000 volts, but 40,000 volts was the result of an actual test.

THE SPRAGUE ELECTRIC ELEVATOR COMPANY installed twenty-three elevators in the "Big Store" of the Siegel-Cooper Company. They publish a long list of other buildings where their elevators are in service, and it includes many of the largest in the country.

NEW YORK NOTES.

J. D. MILLER & COMPANY are installing two 200 h. p. Fitchburg engines, together with boilers, piping, etc., in the plant of the Mt. Morris Electric Light Company, at 2283 Eighth avenue. The entire plant must be in running order by December 1.

MR. J. L. SOMOFF, has again started out independently to manufacture miniature lamps, Crookes tubes and induction coils. He has established a well equipped factory at 534 Linwood street, Brooklyn, N. Y., which he has equipped with the latest devices and standard instruments.

LONG BURNING ARCS.—Encouraging reports regarding the success of its long burning arc lamps continue to be received by the General Electric Company. A large number are in use in shops, stores, theatres and halls and they are now being largely purchased by mills, the shadowless light proceeding from the globe rendering them especially valuable for mill work.

THE STANDARD DICTIONARY. Funk & Wagnalls Company, New York, have just received a single order from one firm for 100,000 copies of their celebrated "Standard Dictionary of the English Language," amounting at retail to nearly one-quarter million of dollars. This is the largest single sale of so large a work ever made in America. Previous to this one large transaction, over 100,000 copies had been issued, and the company is still receiving many large orders from its subscription agents throughout the world.

STUCKY & HECK ELECTRICAL MFG. CO., (LTD.), 35 N. J. R. R. avenue, Newark, N. J., make a specialty of taking in old electrical machines and reconstructing them for entirely different purposes from those originally intended. There are very few shops where this class of work can be done, it is claimed. Their largest business that for which they are likely most favorably known is their repair work, on every system, armatures, power generators, motors, transformers, lighting dynamos, etc., also rewinding and constructing. Messrs. Stucky & Heck are both practical men, and, with a large force of efficient hands in their factory, are in a position to turn out work in a highly satisfactory manner.

WESTERN NOTES.

MR. M. M. WOOD, who is well known amongst the Western electrical trade, has accepted a position as electrical engineer to the Ohio Brass Company, and will hereafter be located at the headquarters of that company at Mansfield, O.

THE BALL ENGINE COMPANY, who throughout the long period of business depression have been strenuous to maintain the quality of their machinery, find a reward in the fact that their shops at Erie, Pa., are filled with orders at prices very considerably above those quoted by others and that they have work many months ahead. A number of these orders are from foreign countries and were entirely unsolicited.

THE ST. LOUIS IRON AND MACHINE WORKS have issued a very neat little brochure devoted to their heavy duty St. Louis Corliss engine, intended specially for use in the electrical field, to meet the conditions of great strength, constant regulation under wide changes of load, ability to stand sudden and continuous overload, and economy in operation. The pamphlet contains several cuts and many interesting details.

THE BORDEN & SELLECK COMPANY, 48 and 50 Lake street, Chicago, Ill., report fairly active business in their coal and ash handling machinery for power houses.The following recent contracts have been put in operation: Ash and soft coal handling conveyors for power house of North Shore Electric Company, Roscoe boulevard and California avenue; also power house of same company at Edgewater. Soft coal conveyors, steel storage tanks, etc., for carrying coal from side track through a tunnel under street and factory, delivering same into the battery of boilers, for James S. Kirk & Co., soap makers, North Water, near Rush street, this city. Contract has just been closed with the Chicago Library Company for anthracite coal and ash handling machinery for the new library building. Recent orders have been filled as follows: Tennessee Coal, Iron and Railway Co., Pratt City, Tenn; Howard Harrison Coal Co., Bessemer, Ala.; Choctaw Coal Co., Anderson, Ind. Ter.; Schloss Iron & Steel Co., Birmingham, Ala.; Toledo Traction Co., Toledo, O.; Elmwood Coal Co., Elmwood, Ill.; Dora Coal & Mining Co., Horse Creek, Ala.; Pablo Gamiz, Havana, Cuba.

NEW ENGLAND NOTES.

THE W. S. HILL ELECTRIC COMPANY, of New Bedford, Mass., have published some data in sheet form, giving the information necessary for designing switchboards and drilling holes for mounting switches. These sheets cover both 1, 2 and 3-pole switches. About 3,000 copies have been published, and those interested may procure copies by addressing the company.

JEWELL BELTING.—The Jewell Belting Company, Hartford, Conn., have recently, Mr. C. L. Tolles reports, taken some good contracts for large belts in the following places: South Bend, Ind., Electric Company, one 58-inch double, 104 feet long, and one 30-inch double; Albany, N. Y., Illuminating Company, 120 feet of 60-inch three-ply. Additional to these are orders for electric belts of several sizes from various parts of the country.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., notwithstanding the general distress among manufacturing concerns, report that their plant is fairly well employed. At no time during the year have they run on short hours, and are now employing 400 men, running 10 hours, 6 days a week. They have contracts on hand to keep their plant employed on full time for the next two months. They have no very large contracts on hand at the present time, but a great deal of small work. Some of this may be mentioned as follows: For the L. D. Brown & Son Co., at Middletown, Conn., fireproof power plant and also a new dye house; steel framework for the Fire Department Building, at Worcester, Mass.; power station for the electrical equipment of the N. Y., N. H. & H. R. R., at Stamford, Conn.; machine shop for the Baush & Harris Machine Tool Company, of Holyoke, Mass.; new building for the Woonsocket Electric Machine and Power Company, of Woonsocket, R. I.; new steel bridge for the town of Green, Me., including a second bridge for the Cabot Manufacturing Company, at Brunswick, Me., and smaller bridges at Auburn, Pembroke, Turner, Buckfield and Bridgeton, Me.; a new iron roof for Randolph & Clowes, Waterbury, Conn.; steel bridge for Somerset County, N. J., located at Finderne, besides other smaller contracts.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. NOVEMBER 4, 1896. No. 444.

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—VI.

BY LIEUT. B. A. FISKE, U. S. N.

THE ENGINE TELEGRAPH.

THE office of this instrument is to signal to the engine rooms the speed and direction at which it is desired to run the engines.

The telegraph for each engine consists of a transmitter and a receiver, in each of which is an arc of resistance wire. The ends of the resistance wires of transmitter and receiver are connected together by large copper wires, so that they form, with the galvanometer, a "Wheatstone bridge" circuit (see Figs. 9 and 10); and since the two arcs of wire are exactly similar, the galvanometer will not deflect, if the contacts to which the galvanometer is joined are placed on the resistance wires at similar points, such as 1.1, 2.2, etc. In the actual apparatus, the contacts of the galvanometer are attached to the levers on the instruments; so that, if the operator at the transmitter places his lever at any point, the galvanometer will not deflect, if the operator at the receiver places his lever at a similar point.

The operation, then, of using the telegraph is as follows:

The operator on the bridge, or in the pilot house or conning tower of the ship, wishing to signal an order, places his lever opposite the graduation on the transmitter indicating the order. The operator in the engine room moves his lever until the galvanometer comes to zero, and then looks at the face of his receiver, to see the graduation opposite to which his lever then is.

Besides the galvanometer just mentioned, there is another galvanometer in series with it. This galvanometer is on the bridge, and is subjected to the same electrical current as is the galvanometer in the engine room, and is moved to the same extent. The operator on the bridge, therefore, by looking at this galvanometer can tell whether or not the galvanometer in the engine room is at zero; or, in other words, can tell whether or not the operator in the engine room has moved his pointer to the signaled position; so that the galvanometer on the bridge acts as an answering signal to the operator there. The galvanometer in the engine room is mounted in a vertical position on the lever of the receiver, so that the galvanometer and lever move together. (See Figs. 11 and 16.) Its electrical connections are such, that if the needle points in any direction, the act of moving the lever of the receiver in that direction will bring the needle toward zero. Furthermore, the sensitiveness of the galvanometer is so adjusted during installation that the amount of deflection of the needle shows the amount of movement necessary to give the lever. If, therefore, the levers are at 75 and the transmitter lever is moved to 90, the receiver galvanometer will at once point to 90. When the needle is at zero, it is in a line from the center to the indicating finger on the lever; so that, in order to bring the needle to zero, the operator at the receiver moves his lever toward the needle and until it is directly opposite it. In other words, the mode of procedure of the operators, both on the bridge and in the engine room, is the same as it is with the ordinary mechanical engine telegraph.

The receiver's galvanometer, however, owing to the vertical position in which it stands, is not absolutely exact. It is possible to make with it an error of two or three revolutions.

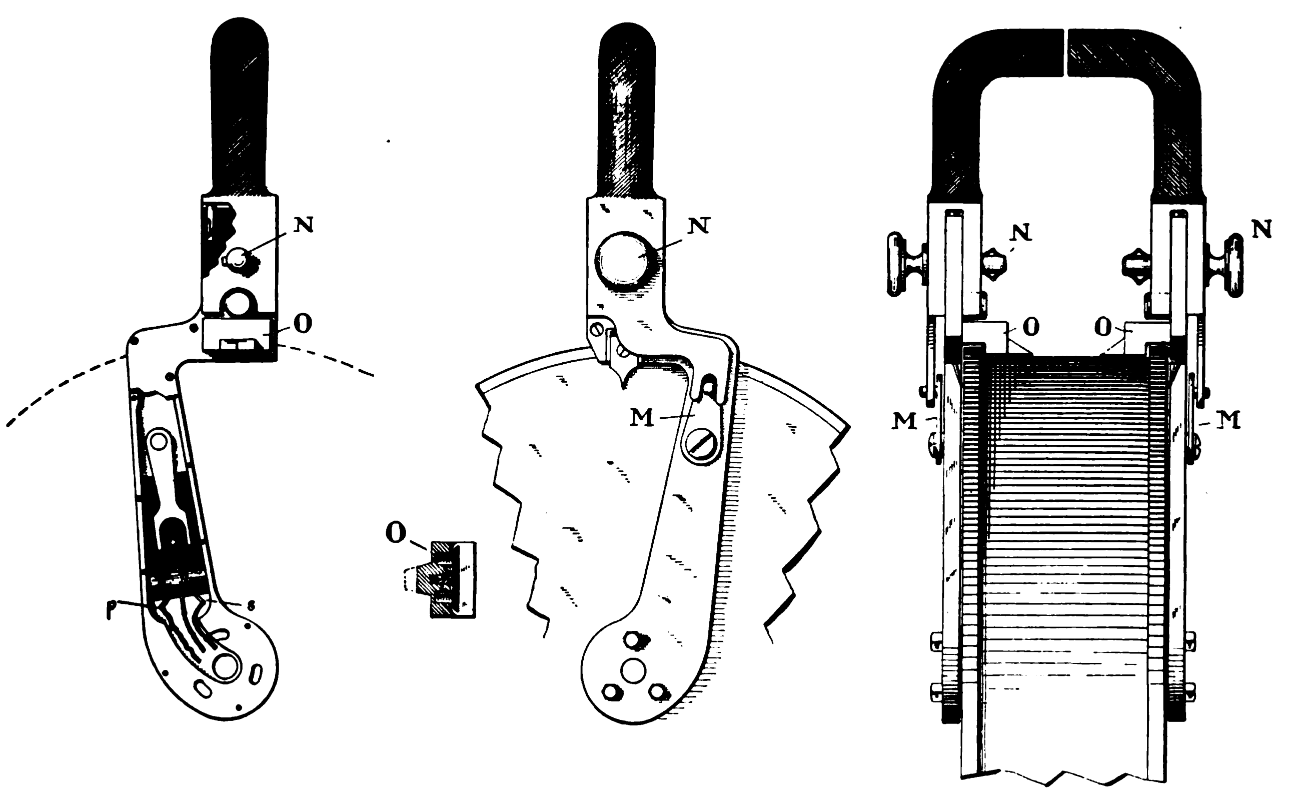


FIG. 12.—TRANSMITTER HANDLE OF ENGINE TELEGRAPH.

This error is of no consequence in the ordinary use of the engine telegraph, but for squadron sailing greater exactness is desired. To insure this, an auxiliary galvanometer, g', lying in a horizontal plane is placed directly below the receiver. (See

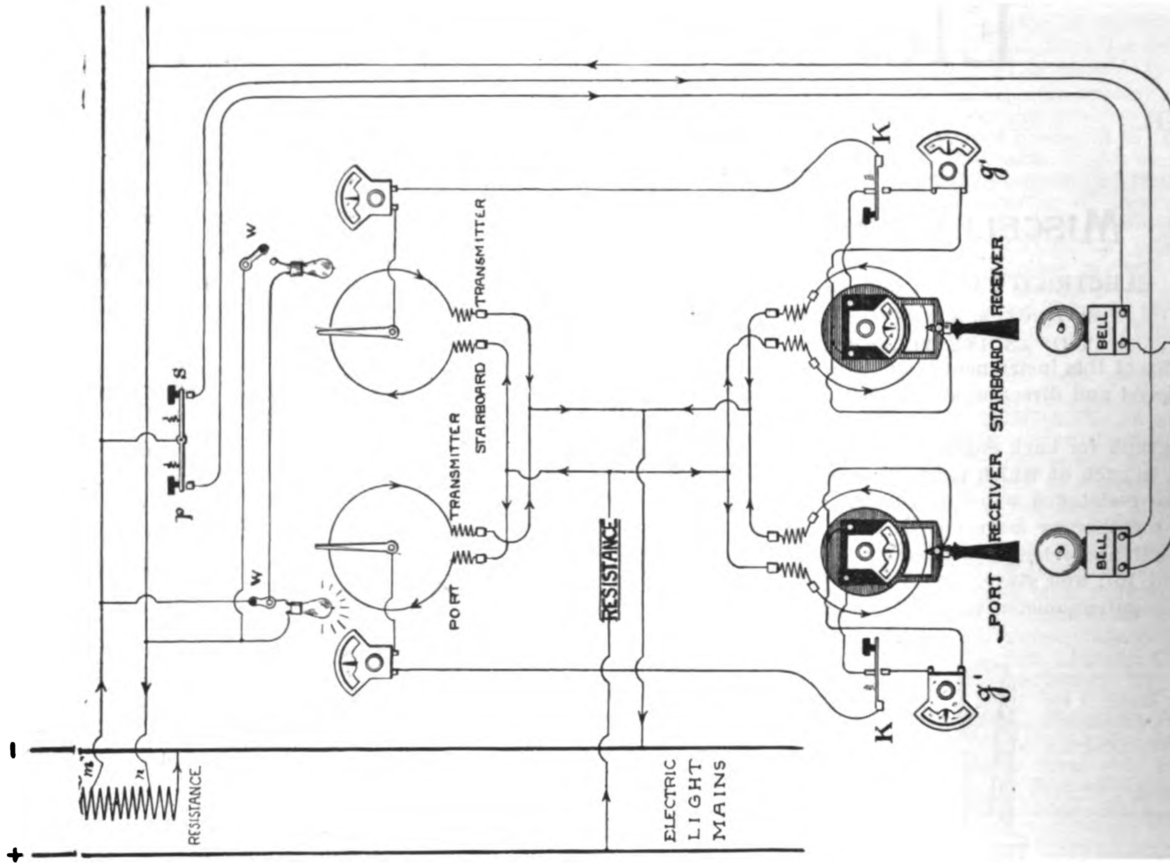

Fig. 11.—Engine Telegraph, Diagram of Electrical Connections.

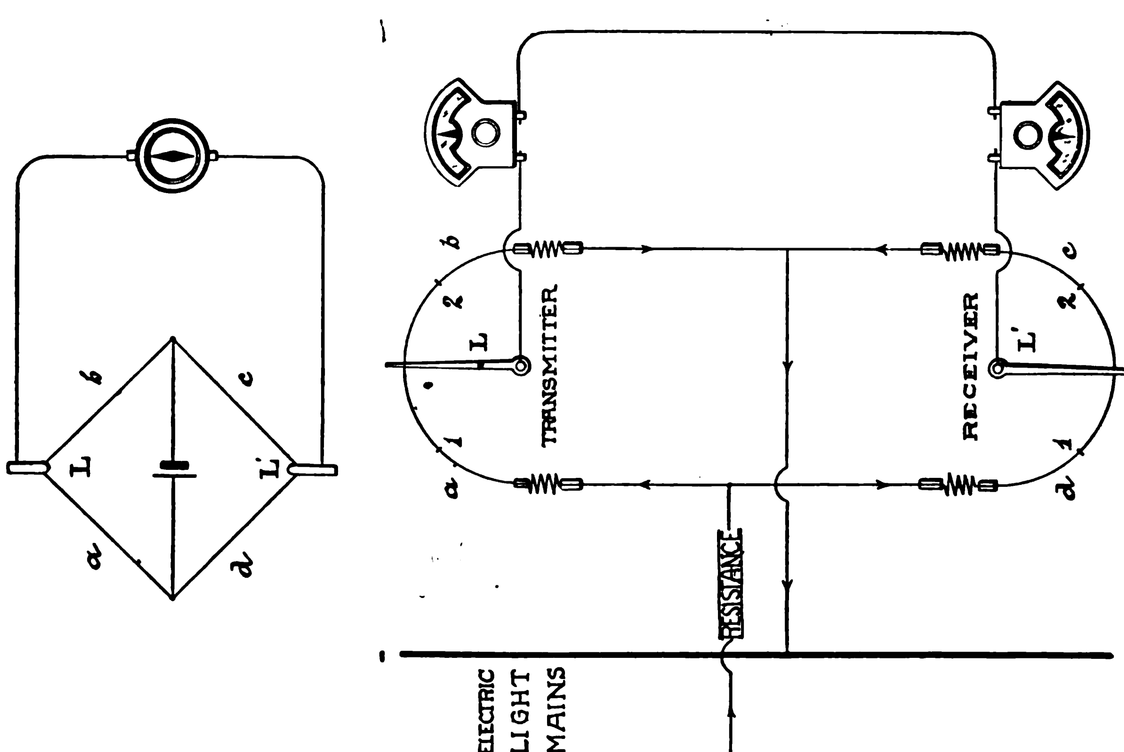

Figs. 9 and 10.—Engine Telegraph, Diagram of Electrical Connections.

Figs. 11, 16 and 17.) Ordinarily, this galvanometer is not in circuit, and no attention is paid to it; but if it is desired to get a careful reading, it is merely necessary to press the key, K, on its top and to move the lever of the receiver until its needle comes to zero. The act of pressing the key on top of this galvanometer puts the current through it and out of the vertical galvanometer, which is ordinarily used, but does not disturb the galvanometer on the bridge.

The expression, "galvanometer needle comes to zero," means that the galvanometer needle comes to a marked position in the middle of the scale, but does not mean that it comes to its position of rest. There would be an objection to having the galvanometer needle come to its position of rest, to get the reading; because the needle will take its position of rest, not

only when the receiving and transmitting instruments indicate the same thing, but also if the battery fails, or if the circuit is broken; so that the operators might think the system was in balance and operating properly, when, as a matter of fact, it was not operating at all, and would fail the first time they attempted to use it. For this reason, each galvanometer needle is bent away from the middle point marked on its scale, so that its position of rest is about 1/16 of an inch from this mark; but the electrical adjustments are such that, when the levers of the transmitting and receiving instruments are at similar places, the "bridge" is not exactly in balance, but is person may have displaced the lever. But as soon as they see that this does not alter the position of the needle, they know that the instrument requires attention. In other words, this system detects itself, if it gets out of order, and reports itself at once, instead of waiting until some one tries to use it, and then, failing in an emergency, as mechanical telegraphs often do.

The apparatus may be operated either from a dynamo current or from a storage battery, or primary battery, or dynamotor. In Figs. 10 and 11 it is shown as operated from the regular electric light mains of a ship, a suitable resistance, about 38 ohms, such as a Carpenter rheostat, being inter-

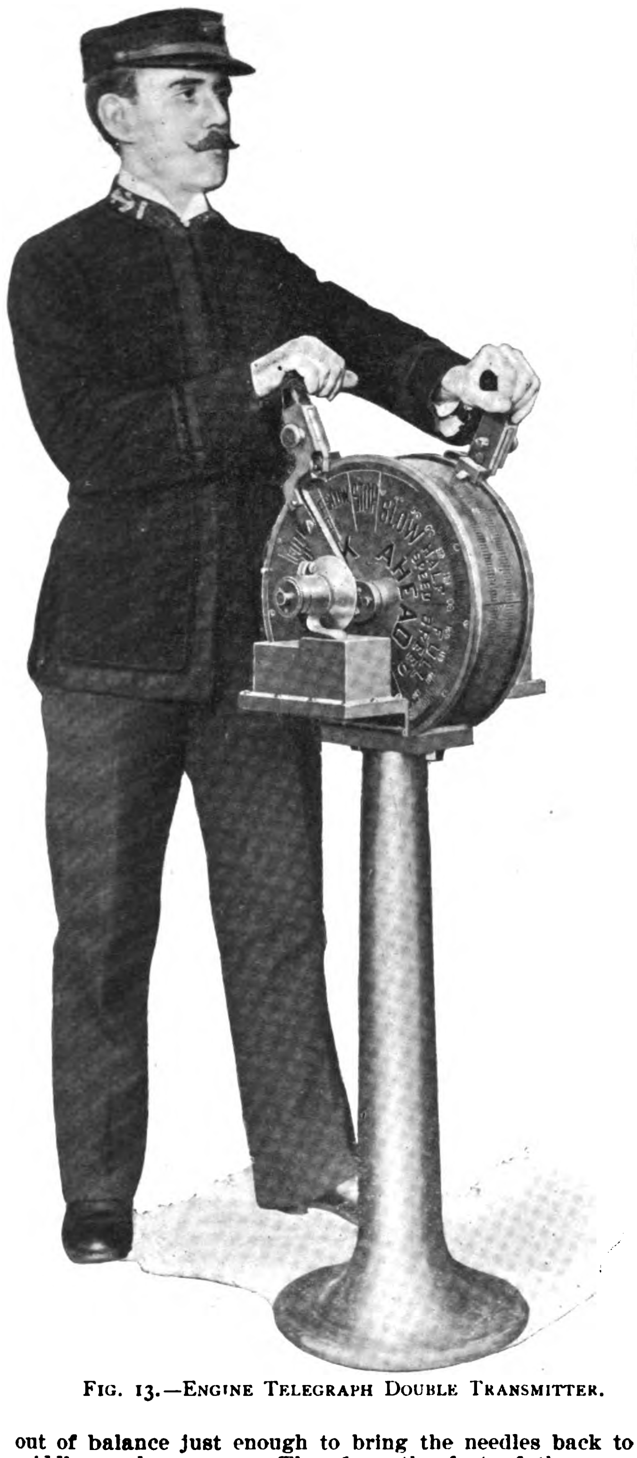

FIG. 13.—ENGINE TELEGRAPH DOUBLE TRANSMITTER.

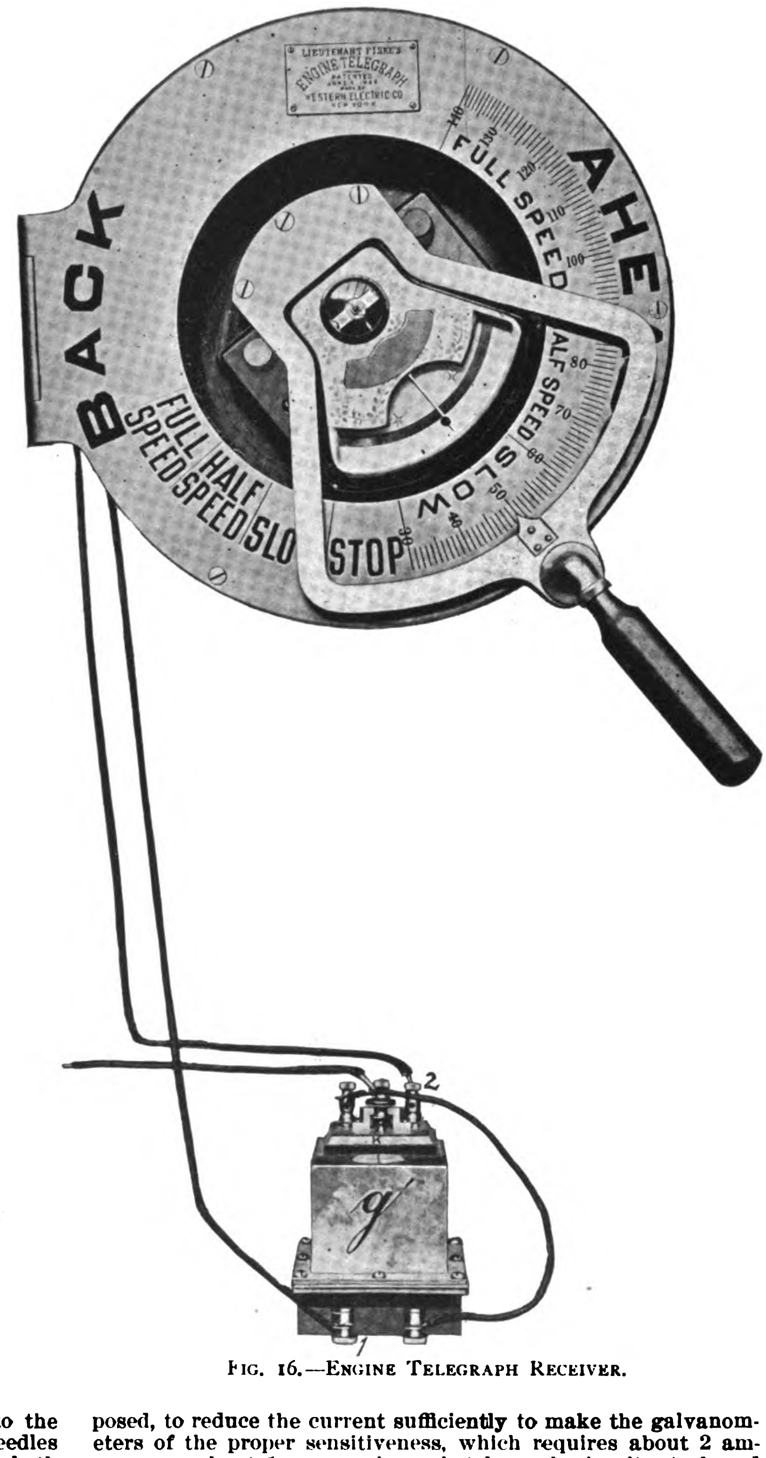

FIG. 16.—ENGINE TELEGRAPH RECEIVER.

out of balance just enough to bring the needles back to the middle marks or zero. Therefore, the fact of these needles being at zero is proof that the circuit is in balance, that both transmitting and receiving instruments indicate the same thing, and that the whole apparatus is in perfect order. If, therefore, the operators at each end see that their needles are at zero, they know that everything is all right; but if at any time they see the needles are not at zero, they know that something is wrong. The first effort will naturally be to move the lever, in order to return the needle to zero, thinking that some posed, to reduce the current sufficiently to make the galvanometers of the proper sensitiveness, which requires about 2 amperes, or about 1 ampere in each telegraph circuit, starboard or port, or ½ ampere in each resistance wire. As shown in Fig. 11, one pair of connecting wires is made to do the service of connecting both transmitters to both receivers. The resistance of each arm of the "bridge" is about 3 ohms.

The circuits of the bells and of the lamps which illuminate the transmitter are connected to the dynamo circuit through a resistance as shown in Fig. 11. The lamps for illuminating

the transmitter are lit by turning the small screws, W, Fig. 14, at each side, and can be taken out and replaced by others if found defective. These lamps are about 1 candle-power,

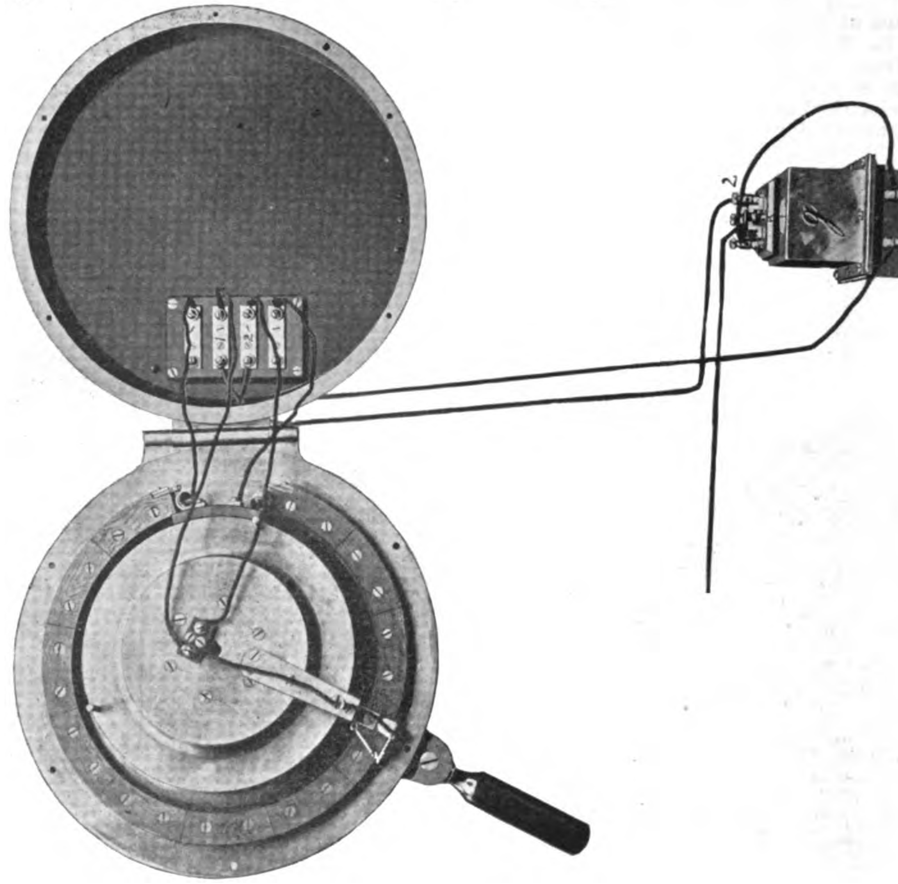

FIG. 17.—ENGINE TELEGRAPH RECEIVER SHOWING CASE OPEN.

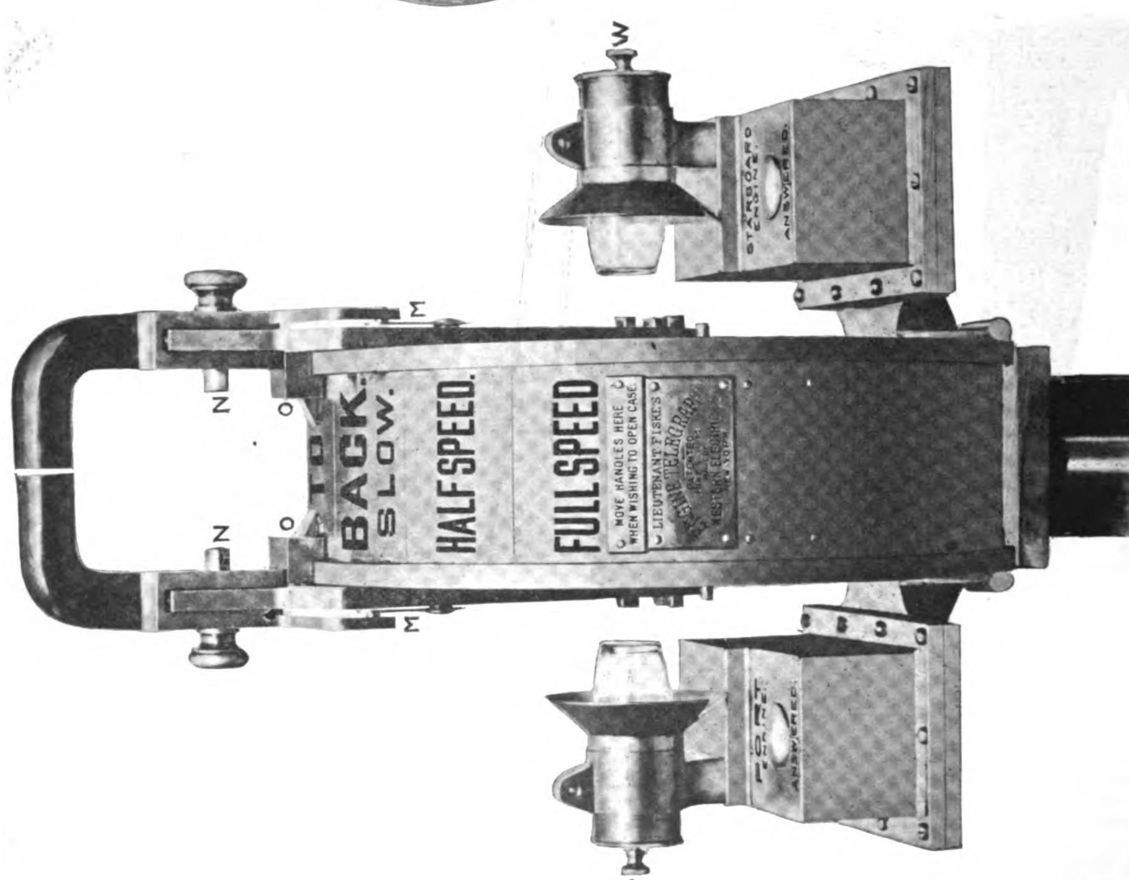

FIG. 14.—ENGINE TELEGRAPH.—REAR VIEW OF DOUBLE TRANSMITTER.

and are placed inside the reflectors shown on top of the galvanometer cases, g, on each side of the transmitter. The lamps and bells usually require about 10 volts each; so that the difference of potential between m and n, Fig. 11, should be about 10 volts.

Any part of the apparatus, including the galvanometers, can be taken apart, examined and repaired, if necessary, by a careful mechanic.

The arcs of resistance wire in the transmitter and receiver

on which the contacts move are covered with vaseline before being installed, in order to prevent undue friction between the wire and the traveling contact. These wires should be examined from time to time and more vaseline put on as required. They should always be covered with a thin layer of vaseline or oil.

The act of grasping one of the handles of the transmitter closes the electrical contact, P or S, on the lever (see Figs. 11 and 12 and 14) by means of the lever, M, and rings a bell in the corresponding engine room. The bell contacts are covered in and arranged as shown in Fig. 12, and well protected from dirt and water. Water in these contacts will not close the circuit, but if they should get dirty they might not permit the closing of the bell circuit when desired. The transmitter handles may be taken off by pulling out the pin, N. These handles are held in position on the rim of the transmitter by means of the spring friction piece in the sliding piece, O.

In case of any trouble with the engine telegraph, the difficulty, in nine cases out of ten, can be traced to some imperfect contact. The contacts most likely to require attention are those of the key, K, on the top of the small horizontal galvanometer, g', under the receiver. If these contacts fail to touch each other, the galvanometer on the bridge, and the vertical galvanometer in the engine room will not receive any current, and, therefore, their needles will not deflect.

A considerable amount of insulated resistance wire, about 2½ ohms, is added to each end of each arc of wire, as shown in Figs. 10, 11, 15 and 17, in order to increase the amount of resistance in circuit of this kind of wire, in comparison with the resistance of the copper connecting wires. This makes the resistance of the resistance wires in each arm of the "bridge" about 3 ohms. The reason of this is that copper changes in resistance with change of temperature, and it is not desirable to have changes of temperature to alter materially the resistance of the circuit. The resistance wires, a b and c d, are of No. 22 American gauge, and made of rangefinder alloy, i. e., 70 parts copper and 30 of nickel, with a resistance of about ⅓ ohm per foot. The copper wires connecting a b to c d are No. 6 gauge, being made so large to avoid copper resistance. The bell wires, galvanometer wires, electric light wires, etc., must not be less than No. 16 gauge.

As shown in Figs. 13, 14 and 15, both the transmitters are mounted on one pedestal and form a double transmitter.

When there is but one engine, the apparatus is correspondingly simplified and cheapened. In the case where it is not necessary to signal any exact number of revolutions, the graduations for revolutions on both transmitter and receiver, and the horizontal galvanometer, g', under the receiver, may be omitted and the instruments made much smaller and cheaper.

In the case where more than one double transmitter is required, as in the Brooklyn, where three will be required, a switch is placed on the pedestal of each double transmitter, which carries four knife contacts. By moving this switch in one direction, or the reverse, the connection is made or broken to both ends of the resistance wire, a b, and both ends of the galvanometer wire. To get ready any transmitter for use, then, it is merely necessary to move its switch in the direction marked on the pedestal. When any such transmitter is not in use, its switch must be moved to the "not in use" mark.

The covers of the transmitters and receivers are made to open on hinges, as shown in Figs. 15 and 17, respectively, so that the connections are readily accessible for examination. Before endeavoring to open the transmitter the user must take off the handles.

The copper leading wires within the transmitters and receivers that are connected to the forward ends of the arcs of resistance wire are covered with yellow braiding; those connected to the after ends with green braiding; those to the galvanometers with green-yellow braiding; those to the bell contacts in the transmitter handles with red-yellow braiding, and those to the lamps with black braiding.

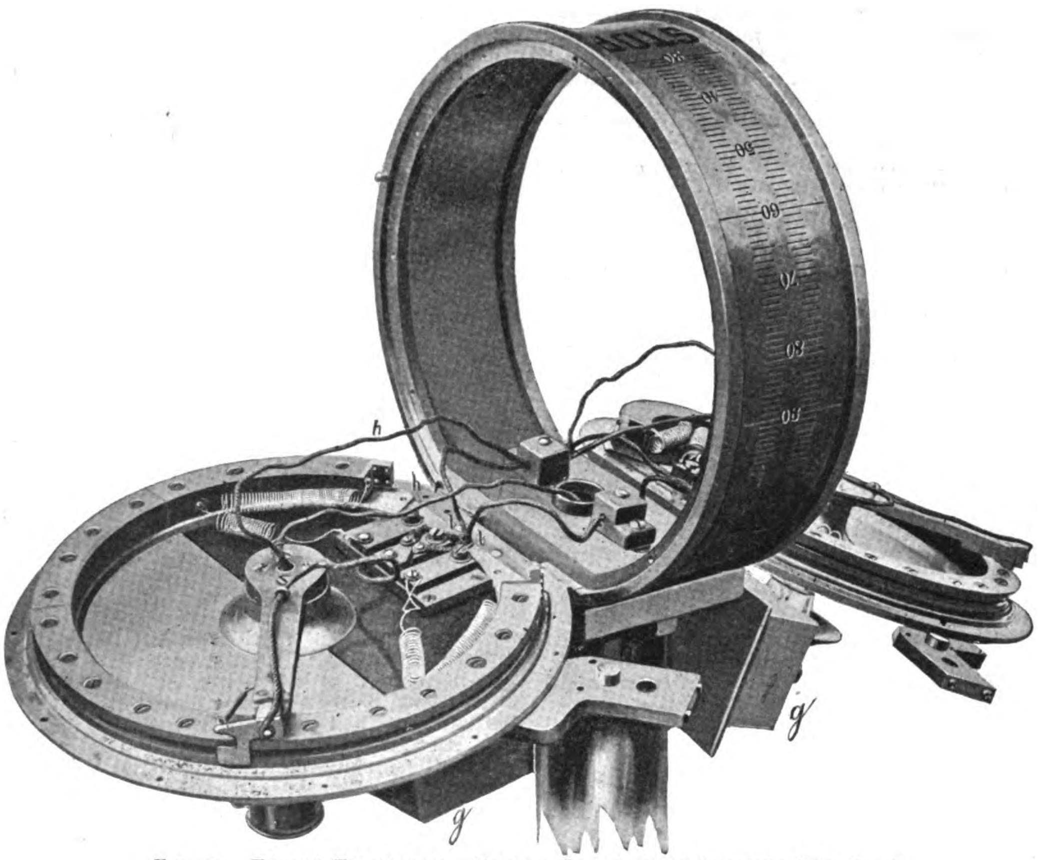

FIG. 15.—ENGINE TELEGRAPH.—DOUBLE TRANSMITTER SHOWING CASE OPEN.

For engines whose speed ranges between 30 and 140 revolutions, the arms which carry the contacts that move over the resistance wires in both the transmitters and the receivers are so connected to the handles that, when the handles are at 85 revolutions ahead, the contacts are at the middle points of their respective arcs; and in constructing and installing the instruments the 85 revolutions mark is the place where the most care is taken to make the instruments balance exactly. The reason of this is that, since the resistance wires are never exactly uniform, the further away the contacts get from the middle points, the more error is apt to creep in; and by making 85 revolutions as the middle point, the contacts do not get far away from it in either direction, even when going as fast as 140 revolutons, or as slow as 30; so that errors as great as ½ revolution are rarely found.

For engines whose maximum speed is greater than 140 revolutions, or less, the same rule applies, though the middle graduation will, of course, be some number greater than 85, or less.

This engine telegraph was given a year's trial in sea service on board the U. S. S. New York. The test having been successfully passed, the apparatus has since been installed on

board the U. S. S. battleships Indiana and Massachusetts It is now being installed in the Texas, and is to be installed in the Brooklyn.

Weight of double transmitter complete, 140 pounds.
Weight of receiver complete, 80 pounds.
Diameter of face of transmitter or receiver, 14⅝ inches.

ELECTRIC TRANSPORTATION.

STREET RAILWAY TRUCKS.[1]

BY J. N. AKARMAN.

AFTER a long and expensive experience, it has at last been generally conceded that trucks are necessary for carrying a modern street car. The term truck in this case means the separate frame work for holding the running gear of an electric car; namely, the wheels, springs, brakes, motors, etc. This being the case, the question arises as to what form or type of truck is best adapted to the purpose, and the object of this paper is to endeavor to give some hints to street railroad men which will enable them to solve this question themselves. In doing this, it will be necessary to explain the principles involved, the requirements of the service, and show where single and where double trucks are most desirable.

When motors were first placed upon street cars, it was believed that there was no necessity for special construction, or any marked departure from the prevailing horse car practice. The idea of a separate truck had not even been conceived. We found Van Depoele placing his motors upon the front platform, and using chains and sprocket wheels to carry the power to the axle. Sprague made a short step in advance and in the right direction by carrying his motor on links from the car body resting one end through sleeves, on the axle. This improvement preserved the distance always the same between the motor and the axle, but the rising and falling of the body imparted a racking motion to the motors, which was destructive to the cars. Both of these systems were radically wrong, and might have been known to be so, from a study of the steam coaches of fifty years ago, and from the steam wagons of fifteen or twenty years previous.

Thie idea of a separate truck was first conceived about the year 1885, but it was not until the latter part of 1887 that, in its concrete form, it was put into operation. The first truck consisted of a continuous upper chord made of bar iron in the form of a rectangle. Its purpose was to support the car body, the sills of which rested on its frame. The sides of this upper chord were re-enforced by heavy oak sub sills to which the chord and the pedestals were both firmly bolted. This form of frame kept the body square and took many of the strains on itself; but it has been abandoned, and in abandoning and using separate bars, I think we have been drifting away from the best practice, for it had a very important advantage in preserving the squareness of the body and truck. In addition to this upper chord, there was a bar extending around the truck to which the bottom of the boxes was fastened.

In all the early trucks the frame rested directly on the journal boxes. The jar and concussion which resulted crystallized the metal, injured the motors, and made it impossible to keep bolts and nuts tight; and was the cause of a rapid destruction of the whole truck. A remedy became an imperative necessity. So elasticity or cushioning of some sort was resorted to; and the first effort in this direction was made by placing a thick piece of rubber upon the top of the journal box between it and the axle box frame. While the principle was right, the means employed was of little value. The rubber at best had only a trifling elasticity, and was not durable and did not prevent the box from jolting.

Then a spiral spring was tried upon the top of the box. This was an improvement as it had a certain amount of motion; but the space available over the box was so small that a very stiff spring had to be used; so stiff in fact was it necessary to make the springs that they were but little better than the rubber. It was found that springs in this position had the additional disadvantage of aggravating the rocking of the box from side to side; but by widening the box at the bottom, or adding ears so as to form spring seats, it was found possible to give each box two springs, one on each side, and of ample diameter and length so that they would carry the load with ease and have sufficient motion. Thus placed they had the advantage of carrying the box perfectly steady, preventing entirely the rocking and unsteady motion. (It should be noted here that the motors were carried on the truck and were in no way attached to the car body nor connected with its motions.)

So far as I can learn, the first car body carried on a separate four-wheeled truck was run on the Scranton and Suburban Railway Company in Scranton, Pa. About the same time, the Boston and Revere Beach Railway Company in Massachusetts had a car, the body of which was mounted upon a truck; from the frame of the latter, the motor was carried in the modern fashion. This car was operated under the eyes of the officials of an electric railway company, who watched its operation from day to day with the most careful attention, and it required but a few weeks of service to demonstrate that the principle was a great one, and that a very important advance had been made that was to mark an era of success in the operation of electric cars.

These first trucks, although involving nearly all the essential features of the modern trucks, were by no means perfect, and the conditions of the service soon suggested modifications. The first of these was to make the removal of the wheels and axles as easy and practicable as they had been with the jaws and oil boxes used on the old horse cars. The form which the improvement took was the making of the jaws a part of the motor truck frame, so that upon jacking up the truck the wheels could be rolled out. This was an essential feature recognized by all truck builders, and has been embodied in every successful truck which has been constructed.

Up to this time brakes had been invariably hung from the body of the car. But it was soon found that brakes upon electrics were a very much more important feature than they had been upon horse cars. The high rates of speed and greater weight of the cars not only made stopping more difficult, but the shortness of stops to avoid accidents was found to be important. The brakes were first suspended from the sills of the car, and the sinking of the body under a load left the shoe so far from the wheels that in applying the brakes the slack of the chains was increased and could not be taken up without considerable delay. The remedy was simple and consisted in suspending the brake rigging from the axle box frame in such a way that it was not subject to the action of the body springs.

The change in the brake rigging from the car body to the truck frame brought another evil which had been of slight importance heretofore. This was the longitudinal rocking or pitching of the car body, technically known as galloping, which was greatly increased under higher speed, and is also futher increased by lengthening the car bodies. This motion is not only excessively unpleasant to passengers, but very destructive to the trucks, motors and track. When the brakes were hung from the car body it was possible to check this oscillation by a slight application of the brake, but the change in the hanging of the brake made this impossible, and remedies became imperative. The first thing that was done as a remedy was to increase the wheel base, but this did not prove to be of much advantage. The first success as a remedy appears to have been made by extending the sides of the truck, and on the extension pieces mounting an elliptic or half elliptic spring. The latter method with the half elliptic spring has been the most successful preventive tried. The necessity for overcoming the oscillation was considered so important, and the success of this device so great that a series of inventions were and are being brought out for the purpose of accomplishing the same result. The so-called extended spring base which is combined with the half elliptic springs has, in my judgment, been the best solution of the problem up to the present time. It is conceded that the equalization of the wheels to carry the load according to the practice on steam roads is out of the question with a car which has only four wheels.

As time went on and experience was gained one point was gradually made more and more evident, which was that a motor truck was a locomotive in every sense of the word, and for success must be governed in its construction by the same general principles that are involved in the construction of a locomotive machine.

As a result of the best information and from large experience, I believe the ideal four-wheeled truck for electric cars at the present time is one having the fewest number of parts in its construction, in which the side pieces of the main frame are single forged bars connected across the ends by bars either bolted or welded on so as to make the frame one continuous piece. This frame is carried by springs from the journal boxes and itself carries an upper chord; likewise, a continuous rectangular piece which has suitable seats for the springs. This upper chord is recessed to take the bolts and spring seats, and leaving its upper surface flush. The ends are carried by the half elliptic springs, while the spirals are placed at the journal boxes. The brake should be hung by links.

So much for the form of construction of a good type of four-wheeled trucks, but what of the disadvantages of four-wheeled

[1]Abstract of paper read before the Am. St. R'way Assoc. St. Louis, Oct 19-23, 1896.

trucks in general? Taken at its best, the four-wheeled truck is an uncomfortable carriage and a veritable track destroyer, and should only be used according to the best judgment of many of our wide-awake railroad men, where cars are run at comparatively slow speed, and with moderate length of car bodies. Where it is desirable to run at higher rate of speed in suburban service the damage to the track becomes so great that it should preclude its use. The increased length of wheel base made necessary makes it hard on curves.

The only alternative is to use a double truck car with swivel or pivotal trucks. The advantage of this form of truck is very great, and while nearly every one is familiar with its good qualities in a general way, I hope I may be pardoned for going into details which are not so well known. They are easy on curves to a degree that would hardly be credited by those who have only been familiar with four-wheeled cars. The greater number of wheels not only reduces the weight on each wheel, but correspondingly reduces the blow when the wheels strike a joint or a low place in the track. This is still further diminished by what is known as "equalization," which practically places the car body at the central point of the truck, so that each wheel in rising or falling in passing over any imperfection in track elevates the load a distance but half as great as its own rise.

Oscillation, whether longitudinal or transverse, can be completely done away with by the use of double trucks. While the trucks conform closely to all the irregularities of the line, the body can move forward with but very little influence from them. The conditions, however, are not altogether in favor of the pivotal truck. As, for instance, if all the weight is used for adhesion it is twice as expensive in use as a four-wheeled truck. If two motors are used, it only has 50 per cent. of the propelling power. In its ordinary form it makes a wide body necessary and hence is out of place in narrow streets or places where traffic is very heavy. It also has the disadvantage of putting the body at a greater height than is necessary with four wheels.

But it meets a great many of the requirements for fast suburban service, and has been indorsed with great satisfaction, but the objection which I have just mentioned precludes its use in many cases where it would have otherwise been desirable. Now the remedy for nearly all these objections has been found in what is known as the "maximum traction" truck.

The "maximum traction" truck may be defined as a pivotal truck in which the load is eccentrically placed in relation to the four wheels. Two of them receive only a sufficient amount of weight to keep them upon the track, while the others take the remainder of the load. In practice it is found that 80 per cent of the weight may be placed on the driving wheels, while 20 per cent. is used for guiding. Upon applying these trucks it was found that it was not necessary to have the wheels of equal size; that a large pair of driving wheels and a small pair of idle wheels can be used. The large pair used as driving wheels being very near the pivotal point have a comparatively small amount of swing, and can be allowed to rise within the floor timbers, while the small wheels moving through a much greater arc easily clear the sills. By this form of construction the body can not only be brought down, but the frame can be made as narrow as in the ordinary street car body. This form of truck enables the car to be utilized for both street and suburban service. It is also found in its latest form utilized under long open cars. It carries the motors in a satisfactory manner, guides readily, and answers nearly all the requirements of the service. But the question of what form of truck answers inter-urban service is one which every railway manager must study for himself. This becomes necessary because the conditions on different roads vary so much that there are scarcely two in the whole country upon which they are identical. The question of the amount of traffic and the headway at which it is desired to run cars involves a careful study. With heavy traffic and frequent stops, it is necessary to have low cars from which ingress and egress are easy. An extra step will increase the danger to passengers very much. On the other hand, where passengers are carried a considerable distance without stops, long cars with more than one step are permissible.

As inter-urban service is almost equivalent to that of the steam roads, for this service pivotal trucks having regular swing beams, equalizers, elliptic springs, and all the parts of the steam road truck are entirely satisfactory. They take curves easily at a high rate of speed. But for trucks which must run not only on trams, but on T rails, some form of the maximum traction truck will give, all things considered, the best service.

In conclusion let me call attention again to this very important question to be considered in connection with the adoption of single and double trucks, which is whether the punishment to the track by single trucks is not so great as to more than make up for the cost of putting in and running double trucks under cars of all lengths of bodies, whether short or long.

THE MODERN POWER HOUSE.—II.

BY R. MC CULLOCH.

STEAM CONSUMING APPARATUS.

THE question of the selection of the proper engine to operate the plant is so dependent upon what dynamo is to be used that it will be best to abandon our arbitrary classification temporarily and take up first the question of the dynamo. During the past four years the street railway generator has undergone a radical change. In the spring of 1893, there were installed in this city, in the power house of the Cass Avenue & Fair Grounds Railway Company, then being built, the first large direct driven generators of this type, which has since become so common. Soon after this the Intramural power house at the World's Fair was put in operation, containing one generator of the same size as those in St. Louis and another of twice the capacity. Since that time there have been few large power houses built in which direct driven generators have not been installed, and some of the large railway systems have found that economy of operation required a change from the belt, countershaft and unit of small size to the large direct driven generator. At the present time, the West End Railway Company, of Boston, which may be considered the pioneer in this country in electric traction, is changing its central power station, which had originally been equipped with a very complete and elaborate system of belting and countershafting, to a direct coupled plan.

The first cost of the direct coupled generator is about 35 per cent. more than the belted generator in the 500 k. w. size, which is the largest standard size in which the belted generator is made, but when the expense of the belt, belt tightening device and the floor space is taken into account, the direct connected generator will be found the cheaper. Besides obviating the necessity of the costly and cumbersome belt, the direct connected generator offers the following advantages: in large sizes and in conection with large engines it has a much higher efficiency than the belted unit, it requires a small floor space, it aids supervision by bringing the working parts of the engine and generator close together, it reduces danger, it is almost noiseless in operation, and it may be installed in a larger unit than the belt driven generator, which is limited in size by the width of the belt and pulley which may be employed. The main objection which was urged against the direct connected generator was the fact that the shocks resulting from overloads were thrown directly on the engine, and that there was none of the cushioning effect that a belt connection might supply. While this is undoubtedly true, the best argument which may be submitted against it is that none of the installations of direct driven generators can trace any trouble to this source. The large, slow speed, multipolar, direct driven generator has become, perhaps, the most prominent feature of the modern power house, and while there may be special services which would necessitate a belted arrangement, it is difficult to imagine a power house thoroughly up to date without direct driven generators.

By varying the number of poles and the number of armature conductors in the construction of a dynamo, the machine may be designed to run at almost any reasonable speed, the slower the speed, however, the greater being the cost of the dynamo. In the matter of speed it is necessary for the dynamo maker and the engine builder to effect some sort of a compromise, because it is not good practice to run such large engines at too high a speed. The speeds which are most common are 75 r. p. m. for the 1,500 k. w. dynamo, 80 to 120 r. p. m. for the 800 k. w. dynamo and speeds running from this to 150 r. p. m. for the smaller sizes. These speeds are what would have been considered, four years ago, quite out of the range of the Corliss valve gear, but the makers of this type of engine have risen to the occasion and now there are numbers of large Corliss engines driving generators at speeds up to 100 r. p. m. and some have even higher speeds than this. Several other types of engines have been adapted to this work and are running quite successfully. Outside of the question of valve gear, most engines made for this work possess the same characteristics; the heavy bedplate, the solidly constructed fly wheel, now being made of steel plate, the wide cross-head, the large connecting rod and the mammoth main bearings.

The choice between horizontal and upright engines is chiefly one of space. The horizontal engine is the cheaper, the simpler, the easier to inspect and the easier to repair. Outside of

the advantage of requiring less space, the upright engine has the advantage of less wear on the cylinder, and a more direct strain upon the foundations.

The usual practice in the most modern power houses is to install compound engines. Most of these plants are so favorably situated that condensers may be operated in connection with the engines. This is undoubtedly good practice, but in case condensers are not used the cost of fuel must be very high for the gain in compounding to pay for the extra investment. Where power houses are favorably situated on bodies of water, condensing becomes a very simple problem, but in case the power house cannot be built on a body of water, as in this city, for instance, in order to use condensing engines, some sort of arrangement must be designed to cool a quantity of water so that it may be used over and over again for the purpose of condensing the exhaust steam. Devices of this kind have long been in use in the city of San Francisco and in Cuba, and lately several of the large manufacturing companies have put on the market complete apparatus for the purpose of cooling water after it has condensed the exhaust steam so that it may be used again for the same purpose. Besides the gain in power by using condensing engines, it is claimed that by the use of this apparatus, actually less water is used than if the steam is exhausted directly into the atmosphere without condensing.

In the use of large direct connected units a great deal of the economy to be gained depends upon the selecting of the proper sizes of units. The efficiency of a generator will be good when it is operated at more than 75 per cent. of its capacity, but the efficiency of an engine drops off very rapidly when it is running below its rated load. In order to achieve the best economy from the use of large direct connected units, the sizes of the different generators should be so proportioned that it is always possible to operate one or more units at their rated capacity. The railway generator as at present built will stand an overload of 50 per cent. for several hours without trouble and at a maximum efficiency. This should be taken into account in the estimate of the dynamos required, but it should always be the aim to have at least one idle machine to throw on the line in case of failure of any of the others. The actual size of the units depends upon the character of travel which the road possesses and the number of cars, and this must be determined for each road independently. In choosing machines, however, standard sizes should always be adopted as this obviates any trouble in obtaining supplies and repair parts.

The railway generator switchboard has become standardized to the extent that it consists of a panel for each generator, each panel containing the usual automatic circuit breaker, ammeter, field rheostat, field switch and main switch. It is hardly necessary to mention that there should be nothing combustible about the board, and it is not an absolute necessity for the board to contain a marble tablet inscribed with the illustrious names of the president, vice-president and secretary. It would confer equal fame and perhaps be more economical of valuable space for their names to be handed down to posterity in some manner less electric. Switchboards as now erected usually contain a recording wattmeter and an ammeter which shows the total output of the power house. The recording wattmeter, especially, is a valuable instrument, as by means of its readings exact records of the power house may be kept.

The modern method of line construction is to divide the trolley into sections and connect each section separately to the main bus bars through feeder panels, each of which contains an automatic circuit breaker, an ammeter and a switch. This method confers the advantages that trouble on the line is always indicated on the proper section, and that in case of short circuits on the line, the main circuit breakers are protected by the section circuit breakers and the load is not suddenly thrown off the engines by the opening of the main circuit breakers. Most of the generator and feeder boards are supplied with devices for preventing damage to the station machinery by lightning, but a very simple and effective arrangement is to connect a large water rheostat between the positive bus bar and a good ground. This is either left in circuit continuously with a small current running through it, or is cut into circuit on the approach of a storm.

Besides those machines which are absolute necessities in a power house, there are various devices which may be added to secure convenience and regulation. An overhead crane is installed in the engine room of most of the large modern power houses and adds greatly to the speed with which heavy repairs may be executed. An oiling system of some sort by which the oil is either pumped or flows by gravity to the different bearings obviates the necessity of manual labor in oiling and insures a steady feed at each bearing. A recording steam gauge is found very useful in checking up the firemen. An air pressure system is beginning to be used in many of the power houses by means of which the carbon dust may be blown out of the armature windings. With this apparatus an armature may be kept thoroughly clean, and the danger lessened of short circuits occurring on account of the collection of carbon dust between its conductors.

HOW CAN THE REVENUE OF STREET RAILWAYS BE INCREASED?—II.

(Concluded.)

BY C. DENSMORE WYMAN.

WHATEVER clever and ingenious scheme may be devised and adopted by the street railway manager for making more attractive the service offered by the company and increasing its patronage, it will fail of its ultimate purpose unless with the growth of business so stimulated he shall exercise a like amount of skill and sagacity in the selection and training of employés upon whose honesty, faithfulness, intelligence and carefulness he can depend. Attractive resorts upon the route of a road may be opened and fostered; a general system of transfers offering great benefits to the patrons of the line may be introduced; new territory may be occupied; in many ways more travelers may be allured to the cars; still, if the fares so brought to the mands of the company's collectors are not honestly handled; if its motive power and the devices for its application are unintelligently and uneconomically managed; and if that measure of discipline which secures the safety of its patrons is not enforced, the increased gain will not be found to result in an increase of the coveted net results.

To state in full the various rules and methods adopted for the securing of the desired charactistics just mentioned on the part of the employés would take too much of our space, already so nearly exhausted. We have not room to speak of the many and various excellent schemes of rewards and prizes offered to their men by not a few companies for excellence in the matter of freedom from accidents, careful handling of the company's property and perfect reports, schemes which have proven most useful and with which it would be well for us all to become familiar.

We cannot, however, refrain in this connection from congratulating the street railroad companies upon the fact that a superior class of men have of late years sought employment at their hands. The motorman or gripman of to-day is the superior of his predecessor, the horse car driver. The conductor of the modern fast moving car with trolley to care for, transfers to issue and a more critical public to serve, must needs be brighter and more capable than his brother of the old style car. The chief engineer, the electricians, the master mechanics and the superintendent are necessarily men possessed of a better education and a far wider range of thought and information than were those whose duties were limited to the care of horses and stables, mule cars and flat rail tracks in former days. As our business has grown in its technical and scientific requirements it is attracting a class of men for whom before there was neither call nor inducement to enter its service.

These facts are to be considered in the selection of our employés. A regular mental and physical examination should precede the appointment of all trainmen, and in the mechanical departments only skilled men, exclusive perhaps of apprentices ought to be engaged. Every effort should be made by the manager and his assistants to enlist the interest and promote the education of the employé as regards his duties and the general characteristics of the business. While it is true that sometimes "A little knowledge is a dangerous thing," we cannot sympathize with that policy which would make of the workman merely an automaton. The rule which some roads have of requiring their motormen to spend a certain time in the repair shops before they take their places on the cars is one worthy of imitation, and various other methods adopted along a similar line of education are to be commended. But with the desire on the part of the manager to educate the faithful men in the ranks must be a determination to prevent the retention or engagement of the dishonest, the intemperate or worthless.

We venture to make a suggestion which may aid in the line of this perhaps. Let it be a general rule of street railroad companies that all conductors, motormen or gripmen must, before entering the service, procure a bond from a reputable guaranty company. For motormen, this bond would be in the nature of protection against damage to property, in the case of the conductor, damage to property and dishonesty. The company selected for the giving of such bonds should be one having agencies in all of the principal cities and towns of the country.

The modus operandi of the bonding would be as follows: The man seeking either of the positions named, would make application in written form with a statement of names of former

employers and their location, and would then be informed that such application would be sent to the guaranty company, and if accepted by them as a good risk, other conditions having been complied with, his appointment would be made. The guaranty company would then in accordance with their usual business methods make inquiry of the reference given, as to the applicant's record, and aside from this, examine all records in their several offices in the various cities to ascertain whether the said applicant had ever been the cause of a loss to them upon any former railroad or other position. With this system in whatever other city the wrongdoer might apply, his second attempt would be likely to be frustrated. The peripatetic fraud would be caught, while the knowledge on the part of those once accepted that if through carelessness or dishonesty their bonds would be forfeited and the record of such a fact placed on the books of the guaranty company would ever prevent another bonding and thus disbar them from the obtaining of another position of trust, would certainly prove a valuable deterrent to initial wrong.

If the street railway companies could but unite in this matter a responsible guaranty company would no doubt be found who would undertake the work as outlined above, and the cost to employés for such bonds could by arrangement be made inconsiderable. The assurance that the records of applicants would be carefully searched and their subsequent actions carefully noted and recorded would certainly serve to discourage bad men from applying, and restrain others holding such position of trust as that of trainmen from yielding to temptation and going wrong.

The methods of an army-like discipline to effect the discovery of offenses and the prompt discharge of the offender, the setting about the camp of guards and pickets beyond which no one may pass, is necessary and effective, but after the practice of many successful military commanders, who, when the battle was set, were accustomed to ride in front of the rank and file of the army, and with words of encouragement and cheer stimulate to deeds of daring and devotion, so may not we with success adopt some method of coming into personal contact with our men, not as stern judges, presiding simply at their trial and prepared to deliver sentence, but leaders, educators and fellow-workmen in the business in which we are engaged. In the case of a smaller company this might be accomplished with comparatively little trouble by the manager or superintendent, making it a point to frequently meet his employés, either in a group, say, at the stations where there are several connected with the system or en masse at some meeting held for the purpose. Thus instead of always presenting himself as a taskmaster, he will be able freely to discuss with them the necessities of the business and the purposes of the company with especial reference to their individual welfare, and he will have the opportunity to bring before them items of general information touching latest developments in the technique of street railroad work. In this way he and his men will be en rapport and more cordial relations will be established between them.

Where a company consists of a large number of lines, requiring the employment of many men and the division of official work among a number of officers, it becomes a question as to the best method to be adopted by the officers for making themselves known to the individual employé other than by the usual style of written orders, promulgated from time to time, and posted in the stations and shops. Having felt the desirability of some other and pleasanter medium of communication with his employés, the writer of this paper about a year ago began the monthly publication of a little sheet entitled "Milwaukee Street Railway Bulletin," and its objects were set forth in a short editorial in the first issue to the effect that the publication was issued in the hope that by it might be effected a closer relationship between the management and the employés, based on a more definite understanding on the part of the latter, of the wishes and intentions of the former. It was also announced that as from time to time changes in the method of running the cars, the use of material and the general operations on the road, in the shops and power plant, might be deemed best by the management, either to test or permanently adopt as the company desire, in order to avail itself of the experience of other companies in their work, when after due investigation such experience seemed to offer something desirable for adoption; and as the usual form of such changes, as far as the employés were concerned, came to them in the shape of some new rule or regulation to be obeyed in most cases without a clear and definite idea of the cause of such ruling; it was proposed by means of the Bulletin to set forth from time to time the reasons for changes made, so that the desires of the company might be thoroughly understood and unity of purpose on the part of both official and employé thus promoted.

It was further set forth that it was the intention of the management to publish from time to time facts and news concerning the business that would be interesting and educating to readers, the results of improvements made on their own and other roads, of the construction and operation of electrical roads, details of which would be usually published in a trade journal, and, perhaps, would not always be accessible to those to whom the paper in question was to be sent.

Following the line marked out for such publication, the little paper was issued each month for more than a year, and in each number suggestions, requirements, rules, timetables, etc., were set forth for the benefit of the employés. Articles on the best means of handling transfers, the care of street railway motors, the treatment of passengers, and particularly the troublesome ones, statistics of the operation of the road and electrical information in general were put in print and placed in the hands of every employé. A personal column was also introduced, in which mention was made of any act showing skill in the avoidance of accidents, in the handling of the motor, etc., and attention was called from time to time to deeds worthy of commendation. To the columns of the Bulletin contributions were invited from the heads of the different departments, and in a column called Reminders, short articles were introduced, calling attention to any laxity on the part of the men in reference to any particular rule, together with suggestions how to act under any especial combination of circumstances. To its columns were welcomed contributions from the men, and queries addressed to the management by employés were answered in its monthly issues.

The publication of the little sheet was in the nature of an experiment, but the fact was speedily developed that the paper was of great utility. Its monthly issues were looked for by the employés, and its suggestions were made matters of discussion at the different stations and gathering places of the men. Hardly a conductor or motorman on the road did not carry his copy with him and often referred to it. The four page sheet soon changed to one of eight pages, 8 inches x 12 inches in size, and a few advertisements judiciously selected paid the expense of printing and distribution.

While the preparation and publication of such a paper will necessarily add to the burden of duty, already sufficiently great in the case of most managers, its value in keeping the men of the line in close touch with their officers by disseminating information of local value in the daily operation of the road, and in stimulating to better efforts by a judicious admixture in its columns of praise and blame and suggestions to those the labor involved in its production. We would recommend to whom it is addressed, will make it worth many times over, a trial by all street railway companies of some such printed sheet for distribution among their employés.

Some companies have fostered what might be termed a benevolent protective society among their men, the officers of the company being included in the scope of such an organization with a voice in its affairs. We regard such societies as valuable along the lines of which we are speaking, and if tact and skill is used in the official relationship of the company to such a club or association, it can be made the medium of the cultivation of pleasant relations between the employer and the employed.

Reading rooms at the different stations and shops provided with technical journals, as well as the daily papers, for the use of trainmen and others can be made most serviceable; and all these methods tend, we believe, to the retention of good men, the cultivation of good principles on the part of the employés, and naturally the elimination of the bad, the worthless and the ignorant. Given a large proportion of honest and intelligent employés upon a road, and by a natural process of the pressure which good always exercises upon evil, the bad will find themselves out of place and will be forced to leave. The work of the detective bureau, important as it is, ought, we believe, at all times to be supplemented by the most liberal efforts on the part of the managers to impress upon their employés, either orally or in printed form the advantages of doing right, the benefits of an intelligent conception of the scientific facts with which in their daily work they are constantly dealing, and the cultivation of an enlightened public sentiment among them, to the end that the dissipated, the ignorant, the careless and the dishonest may be made ashamed, and of their own accord seek other positions more congenial to their tastes. Light dissipates darkness.

AN ELECTRIC ROAD FOR HAYTI, WEST INDIES.

The Berlin Iron Bridge Compnay, of East Berlin, Conn., have a contract for a car barn and shop building for an electric road at Port au Prince, Hayti. These buildings will be of steel throughout, having a steel skeleton framework covered on the sides and roof with corrugated iron. The shop is 33 ft. by 70 ft., and the car barn 40 ft. by 160 ft.. This building is

only one of many which have been gotten out by this same company for export to foreign countries during the past few months.

THE ELECTRIC EQUIPMENT OF BROOKLYN BRIDGE CARS.

THE switching of the Brooklyn Bridge cars by electricity will shortly become an accomplished fact. The cars are being rapidly finished, and as they reach the yards of the Brooklyn Bridge Railroad, will be fitted as fast as possible with the electric apparatus. The twenty car equipments forming the order are now ready in the shops of the General Electric Company, waiting for the cars to reach Brooklyn.

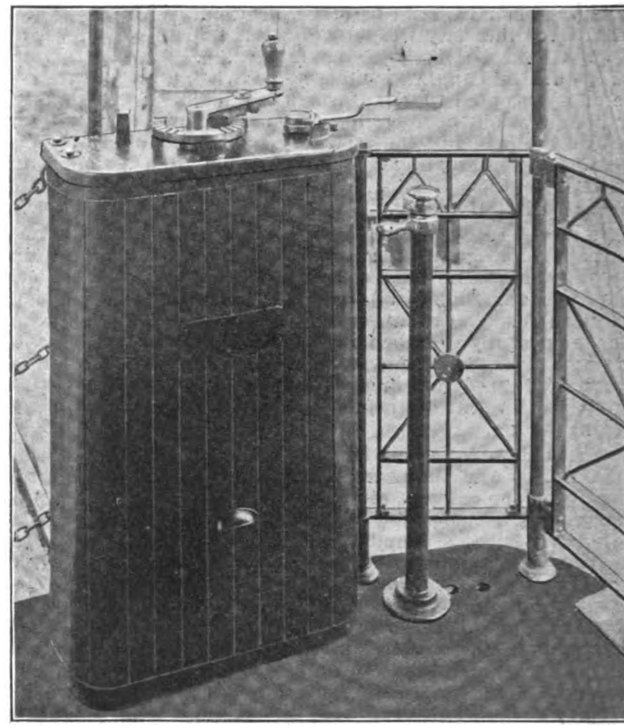
The first car, a handsome piece of car work, reached Schenectady from the shops of the Pullman Palace Car Company a few weeks ago, was fitted with the electrical apparatus, and is now in Brooklyn. The remainder of the cars will be equipped at their destination. The electrical equipment of each car consists of four G. E. 50 motors and two K. 14 controllers, both especially designed for this work. The motors are completely encased, and are water tight and dust tight. The armatures are slotted, each coil lying in its own slot, and the method of winding followed allows of the removal of any coil with very little disturbance to the others. Each motor is provided with a roller which will come directly over the cable and prevent it from abrading the motor or injuring it in any way and from being injured itself.

The K 14 controller is the standard K-type of controller adapted for four motors of the capacity of those which will be used in this case. It embodies all the qualities of the K-type, and, of course, has the magnetic blow-out. Two circuit breakers, a magnetic fuse box and twelve resistances complete the electrical motive equipment.

The only portion of the electrical apparatus which will be plainly in sight, will be the controllers at the extreme edge of the platform and an upright iron post with a small handle to operate the circuit breakers. Motors, resistances, circuit breakers, etc., will all be out of sight beneath the car. The circuit breakers are closed and opened from the platform, but are so placed that inspection can readily be carried out.

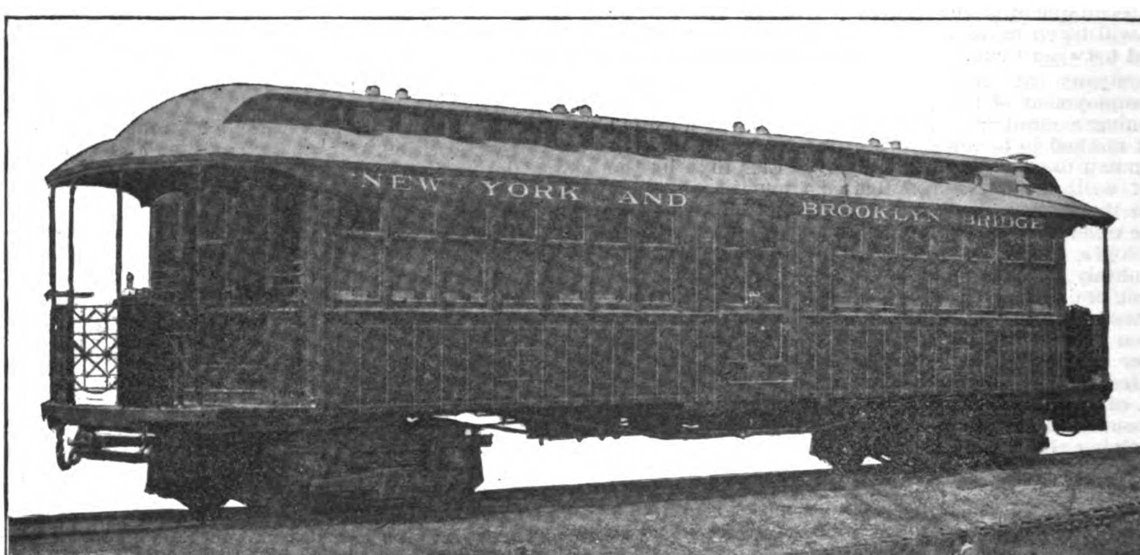
The duty which these motors will be called upon to perform will be to switch the four-car trains from the incoming to the outgoing platforms. When the trains are loaded the motors will push them forward over the tilting sheaves, where the cable will be taken up by the grips on the other three cars of the train. The conditions of the contract between the electrical company and the Brooklyn Bridge trustees, require that in case of any failure on the part of the cable plant the four motors together shall be powerful enough to propel the fully loaded train weighing 120 tons across the bridge at the speed of the cable, i. e., 11.3 miles per hour. The capacity of the motors is such that they will be able to haul the heaviest bridge trains up a 3.78 per cent. grade not only for the short thousand feet—the length of that grade on the bridge structure—but the whole length of Manhattan Island, if necessary. The trucks of the new cars are from the shops of the McGuire Manufacturing Compnay, which has recently constructed the trucks of the electric cars used on the Lake street elevated in Chicago.

The third rail method of contact will be adopted, and current will be taken by four shoes to each motor car, two on each side. These are suspended from a support set between the journal boxes of each truck, and will be so hung as to give a perfect contact with the third rail.



FRONT PLATFORM, BRIDGE CAR, SHOWING CONTROLLER.

As soon as the full number of motor cars is equipped and in service, the steam locomotives will be taken off. This will not only mean a relief to the passengers on the trains, but an actual source of economy to the bridge itself, the gases from the locomotives proving an actively destructive agent to the ironwork of the terminal stations.



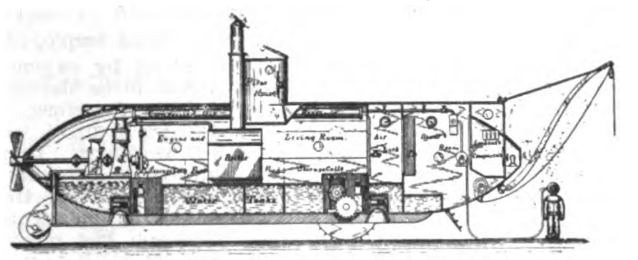
ELECTRIC MOTOR CAR, BROOKLYN BRIDGE.

The question of the abandonment of the cable for the complete operation of the bridge trains by electricity is one which will probably be settled in favor of the cable. The uniform speed given to the cars by the cable, and the fact that the

cars, while attached to it, are spaced at regular intervals, eliminate from the operation of the trains a personal factor, which might tend to accident, while by balancing up grade trains against those running down grade, the consumption of power is reduced to a minimum.

THE LAKE SUBMARINE BOAT.

A CURIOUS and interesting form of submarine boat has recently been devised and built by Mr. Simon Lake, of the Lake Submarine Company, of Baltimore. Experiments already made off the coast of New Jersey, under water, in leaving and returning to the boat while submerged, have encouraged Mr. Lake in the construction of another similar craft of more powerful character. The cut herewith gives a general idea of the boat, which is mounted on wheels or rollers and might be designated a submarine wrecking boat. The plans call for a compound steam engine of approximately 70 horse-power; the motor will be 10 horse-power for driving the wheels, and the generator can also be used as a motor for driving the propeller when the boat is traveling wholly submerged. Mr. Lake informs us that in his original experiments, it was demonstrated that the direct propulsion by the driving wheels on the bed of the sea was much more economical of power than the use of the screw. The dynamo is of 18 kilo-



LAKE SUBMARINE WRECKING BOAT.—SECTION.

watt capacity and charges batteries which consist of 60 chloride cells, type G, 13 plates, made by the Electric Storage Battrey Company, of Philadelphia.

The estimated speed of this strange craft when running on the surface is about 8 miles; and when submerged, about 5 miles. The air supply has been designed to be of sufficient capacity to allow a crew of 6 men to stay on the bottom 48 hours, if necessary. This air is compressed in steel tanks 14 inches in diameter to about 70 atmospheres. The other machinery consists of an air compressor capable of compressing 3,000 cubic feet of free air per hour at 1,000 pounds to the square inch. Provision is also made for a steam, hand and electric pump, for manipulating the water ballast, a foul air pump, and an electric hoist. The traveling endurance of the boat, in service, and when running on the surface is estimated at about 1,200 miles, and when submerged, one charge of the battery is estimated to take care of it for 60 miles at slow speed. The displacement of the boat submerged is about 100 tons. Mr. Lake considers that in wrecking operations, in pier building, recovery of sunken treasure and cargo, and in naval warfare, such a boat has a large and profitable field of usefulness.

PRESIDENT VREELAND PREFERS THE TROLLEY.

WHILE traveling in the West recently, President H. H. Vreeland, of the Metropolitan Traction Company, of New York City, was interviewed at Denver as to street railway conditions and methods. Among other interesting things, he said: "I do not think there is any known system of railroad propulsion, that can compete with the trolley. The press and the public have declared themselves against the trolley, and it has become necessary, by reason of the conditions that surround us, to experiment with some new system to take the place of the overhead wire, which we cannot use, and the cable, which is almost impracticable on account of the irregularity of the streets of New York City. We have been making experiments with a system of our own, which is known as the Hoadley-Knight compressed air system and matters have advanced to that stage where we have been able to make some practical demonstrations of the efficiency of this new system.

"The growth of our business in the past two years has been very large, our roads having carried 45,000,000 more passengers in that period than at any time since the organization of the system. Of course many of the passengers carried by our roads have been taken from the elevated roads owing to the superior facilities given by surface roads through the liberal system of transfers to connecting lines. As an evidence of the popularity of the transfer system note that the average number of persons transferred by our lines is 150,000 daily and for the last fiscal year over 45,000,000 persons were transferred on our lines, representing a business of over $2,000,000. The different lines operated by the companies which I represent employ over 8,000 men and of the 188 miles of trackage but 38 miles are operated by mechanical traction, while on the rest we still employ horses and keep constantly at work more than 8,000 of these animals. The New York system of railways is the greatest in the world, but owing to the many obstacles met with in the construction of mechanically operated roads we have been necessarily slow in equipping our lines with other than horse power. The trolley is by far the most practical and serviceable system we have and of the 14,000 miles of mechanical traction roads in this country 12,000 miles are equipped with the trolley. A very surprising thing to people in the West is the volume of business done by the railroads in New York City. On our Broadway line we operate 400 cars and have 17 miles of tracks on that and connecting lines and during each day of the year we carry over 300,000 passengers. On our whole system, which includes 150 miles of cable, electric and horse roads our daily average of passengers exceeds 700,000. The large increase in the number of passengers carried by our roads does not necessarily indicate a like increase in the business of the various roads of New York, for many of the passengers now carried by our lines were formerly accommodated by the elevated roads; but the standard of surface roads has approached in speed that of the elevated and surpassed it in facilities for reaching different parts of the city."

SHUNT MOTORS FOR ELECTRIC RAILWAY WORK.

IN some of the electric railroads recently installed in Europe by Messrs. Siemens & Halske, of Berlin, in hilly regions, they have employed shunt motors, contrary to the usual railway practice, in which series machines are employed. The principal advantage claimed for the shunt motor arrangement is the return of the current to the line, which is readily and safely accomplished by a proper arrangement of the apparatus. If the car is on a grade such that it maintains its speed without taking current, or rather if the car is able to produce electrical energy, then when the normal speed is attained the surplus work is not used to increase the speed, but is immediately taken up by the motors which then operate as dynamos, and return the current to the line. The accompanying diagram illustrates graphically what percentage of the current required on the up-grade trip by one car is theoretically

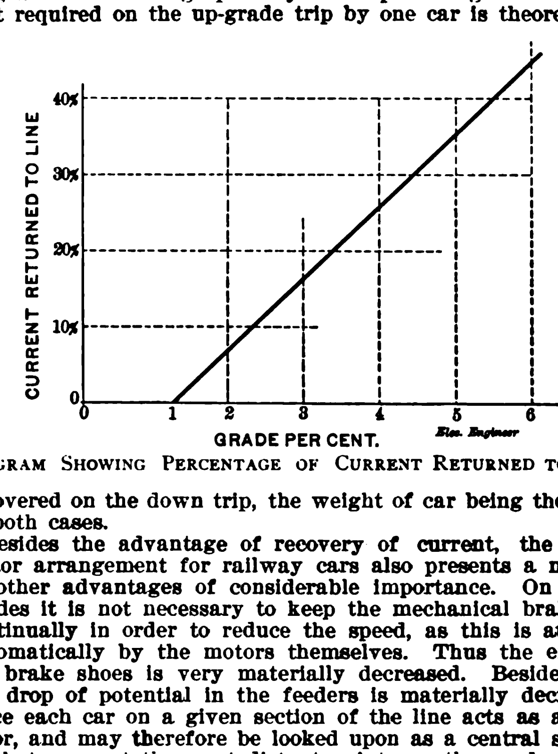


DIAGRAM SHOWING PERCENTAGE OF CURRENT RETURNED TO LINE.

recovered on the down trip, the weight of car being the same in both cases.

Besides the advantage of recovery of current, the shunt motor arrangement for railway cars also presents a number of other advantages of considerable importance. On heavy grades it is not necessary to keep the mechanical brakes on continually in order to reduce the speed, as this is attained automatically by the motors themselves. Thus the expense for brake shoes is very materially decreased. Besides this, the drop of potential in the feeders is materially decreased, since each car on a given section of the line acts as a generator, and may therefore be looked upon as a central station, so that even at the most distant points on the road, according to the contour of the country, the speed of the cars is less injuriously effected by the drop in potential. In consequence of this decreased drop the cross sections of the feeders may also be diminished, and hence the amount of investment decreased.

It follows also that the size of a central railway power station can be smaller for shunt motors, in the ratio of the current recovered.

CONTENTS.

M. MOISSAN'S LECTURE.

THOSE who were privileged to hear M. Moissan's lecture on "The Electric Furnace," will long carry with them the memory of a delightful evening. In the logical arrangement of facts, the brilliancy of the experiments and the elegance of delivery, last Tuesday's lecture was a masterpiece and our brief account of it on another page can give but a faint idea of the charm which the lecturer diffused over the entire subject. But aside from the intellectual treat afforded M. Moissan's listeners, none could have departed without the strongest impressment of the fact that in the electric furnace the electrical engineer, the metallurgist and the chemist had at hand a most potent tool, the limits of whose usefulness no man could now foretell. The manufacture of carbides for the production of acetylene for illuminating purposes is but one and we think a comparatively small part of the work in hand, for we believe that the electric light will maintain its ground in spite of all opposition. Rather do we look for the greatest expansion in the employment of acetylene to obtain some of the most important alimentary products consisting of hydrocarbons, which have heretofore been produced in nature's laboratory only. The innumerable hydrocarbons employed in the arts, many of which are now obtained by expensive processes, may also in many cases be found to be derivable from this protean gas. In this field alone, therefore, the product of the electric furnace may furnish fruitful work for a hundred investigators and countless workmen. In the domain of metallurgy the aluminum industry is an example of what can be accomplished in comparatively short time; and if to this we add the manufacture of carborundum, and of graphite, the latter of which Mr. Acheson has recently accomplished successfully on a commercial scale, it requires no great discernment to recognize the direction in which the next important advance in electrical work may be looked for. If no other signs were at hand the increasing number of patents granted on electric furnaces and their products would of itself show that the opportunities here latent are being seized and turned to good account. We know of no more encouraging field to-day than the electric furnace, for the exercise of inventive genius, and expect indeed that it will at no very distant day rank with the most important applications of the current commercially as well as scientifically.

NEW YORK'S FIRE TELEGRAPH.

VALUABLE property is piled up in New York City to an extent and an amount hardly equaled anywhere else in the world. Owing to the nature of many of the buildings in a city that frequently changes its distribution of trades and population, and owing also to the methods of heating and lighting employed in the winter, the fire risk is abnormally large. Hence it follows that the service for fire alarm and suppression cannot be too good, and that any defect cannot be too quickly corrected. The superintendent of the Fire Alarm Telegraphs in New York City has recently been on trial for fraud and incompetency, and much evidence of an interesting nature has been elicited; but the Board has now closed the case and reinstated the impeached official.

We confess our pleasure at finding Mr. Smith continued in office and our belief that the shortcomings in his department have been due largely to the existence there of Tammany ideals and principles. Mr. Smith has not been a political hack in the sense of going in and out with any party, but we all know what Tammany control of the city meant, and what a man had to submit to in the discharge of technical duties. But that is at an end, and Mr. Smith, both for his own sake and that of this great city, must set his house in order. The evidence as to the condition of the fire circuits and boxes, given by Mr. Carty and Capt. Brophy, men of high repute and standing, betrayed a serious and deplorable lack of efficiency, and this regardless of any special form of apparatus or mechanism. Vigilance will often make poor apparatus work well; but a service run slackly will break down even with the best material and supplies. We trust that in view of the political conditions which now promise the city a purified administration of public affairs for many years to come, Mr. Smith will be able to bring his department into harmonious relation with the better state of affairs generally and will keep it free from all suspicion of improper management.

STREET LIGHTING IN ST. LOUIS.

ONE of the most important changes in methods of street lighting is that proposed for the city of St. Louis, where it is the present intention to abandon arc lights, on the next renewal of the lighting contract, and adopt incandescent lamps instead, the unit being 32 c. p.. This seems to us a retrograde step, and altogether unnecessary. If there is one thing the arc lamp has done it is to prove its superiority as a means of street illumination, whereas we do not know of a single instance in which the incandescent lamp has succeeded in giving satisfaction for city streets. Mr. Edison devised his special "municipal" system for such work, but it has not met with acceptance, although it had many features of merit. In St. Louis the old Heisler system of incandescent lighting outdoors has been well tried, but one does not hear of its popularity there or anywhere else. At one time it looked as though big incandescents of the "Mogul" type might come into vogue for street work, but they have not done so, and the arc has remained in possession of the field. We should greatly like to know the grounds, if there are any, upon which it is intended to make this important change, and would suggest that a better plan would be to improve the arc service up to the fullest extent.

DYNAMOMETER CARS ON STREET RAILWAYS.

THAT most annoying of the many troubles which beset the street railway manager, the track, its construction and maintenance, was well taken in hand in the report of Mr. Bowen, to the American Street Railway Association. How much a company can afford to spend upon its track, is a point on which most railway companies have always been in darkness. While they have a fairly accurate means of ascertaining the cost of haulage per car mile, they are, with perhaps a few exceptions, absolutely without any means of ascertaining the difference between the cost over a good track and that over a poor one, and when repairs are made they are, as a rule, undertaken when further neglect would be palpably ruinous to rolling stock and intolerable to passengers. The use of the dynamometer car as a guide in this case needs no recommendation, and the good work accomplished by it in Chicago is but a repetition of similar benefits obtained by its use in steam railroad work. There are many roads in the United States on which cars of this nature ought to be a permanent part of the equipment, and the sooner they are put in operation the better. For such roads whose limited mileage would make an investment in a dynamometer car of problematic value we would suggest a pooling of issues and a joint ownership with the car employed in rotation on the roads forming the pool. We believe also that an enterprising individual might find it a good investment to equip a dynamometer car and undertake to furnish street railway companies with detailed reports on the condition of their tracks, based on the indications of the car.

TWO THOUSAND ELECTRICIANS IN LINE FOR NATIONAL HONOR AND SOUND MONEY.

SATURDAY, Oct. 31, was not only "Flag Day," but was celebrated in many parts of the Union by large parades in favor of "sound money." The most striking of all these demonstrations was that in New York City, where 103,000 men turned out in line and were reviewed at Madison Square by Gen. Horace Porter, Grand Marshal, Gov. Morton, Mayor Strong, ex-Mayor Hewitt, and others. The route was from the Battery to the reservoir at Bryant Park and Forty-second street, following Broadway, Fifth avenue, and Madison avenue. The whole city was en fête, and was decked in the national colors, every building on Broadway being ablaze with the Stars and Stripes.

About eight or ten days ago, the Electrical Sound Money Club sprang into being spontaneously, with the purpose of participation. It was expected that about 600 might muster and a space was allotted in the Metal Trades Division. But the accessions were so numerous and rapid that some other arrangement became desirable, and in consequence a separate division was made, with Gen. C. H. Barney, of the New York Telephone Company, as Marshal. Headquarters were established in a store at Liberty and Greenwich streets, where a register was opened and a large supply of campaign flags and badges laid in. At 2.40 p. m. on Saturday, the division was ready and reached Broadway and Cortlandt street, where it fell in behind the Goldsmiths and Jewelers' division. The organization was as follows: Brig. Gen. C. H. Barney, Marshal of electrical brigade; Marshal's staff; G. F. Porter, Adjt. Gen. and Chief of Staff; D. C. Cox, Brig. Quartermaster; W. J. Sefton, Commissary; C. O. Baker, Jr., Medical Director; E. P. Decker, Engineer; T. C. Martin, Judge Advocate. Aides-de-camp, F. S. Blackall, C. P. Geddes, C. R. Vincent, E. T. Rice, P. A. Ferry, A. A. Knudson. These were followed by officers of the club as follows: President. E. S. Greeley; vice-presidents,U. N. Bethell, Chas. Blizard, A. L. Salt; secretary, S. L. Coles; treasurer, W. L. Candee. Then came the huge club banner borne by three men, and behind this, having the right of line was the First Regiment, the Crocker-Wheeler Regiment. It followed a fine brass band and consisted of the Ampere Electrical Club, under the command of Dr. S. S. Wheeler, whose staff and aides were F. J. Sprague, G. S. Dunn, F. M. Pedersen, F. M. Jeffrey, W. M. Aikman. It marched like a body of veterans and was splendidly handled. The men took part with the utmost enthusiasm and the Crocker-Wheeler Company ran for them a special train from the works to the city. The number of men in line in this superb regiment under Col. Wheeler's orders was not far from 500, as the regiment included also a strong contingent from the Sprague Electric Elevator Works.

The Second (Telephone) Regiment, headed by a drum corps, was under command of Col. F. M. Anderson and included 250 employés of the N. Y. Telephone Company; Southern Bell Telephone Company; American Tel. & Tel. Company; Consol. Tel. and Elec. Subway Company; Safety Ins. Wire and Cable Company (110 men), Capt. A. D. Eckert; Western Union Tel. Company (50), Capt. H. R. McKenzie. Then came a brass band at the head of the Third (Interior Conduit and Ins. Company's) Regiment, Col. C. L. Pease, employés of that company, 250, Capt. Vandewater; The E. S. Greeley & Company (75), Capt. R. A. Morrison; the Okonite Company; White-Crosby Company; Tucker Elec. Cons. Company; Diehl & Company; Elec. Storage Battery Company; Conduit Wiring Company, Electrical Eng. and Supply Company; The Electrical Engineer, and scattering. This was followed by the Fourth (Western Electric) Regiment, Col. C. F. Nichols; employés of the Western Electric Company (350); Phœnix Interior Telephone Company; Martin Commercial Electric Company; and scattering. This regiment had the famous Rankin Drum Corps, which went through all manner of clever evolutions, eliciting thunderous applause all along the line.

Altogether the Electrical Division showed up with 1,830 paraders, who presented a most creditable appearance and marched splendidly, eliciting special newspaper praise on this score. All carried gold badges of the club on their coats, as well as other special devices, and a great many wore golden chrysanthemums. All political parties were represented in this parade for sound money, and not only were the men from the bench of the electrical shops and pole lines there, but experts and inventors of international reputation. It was a display of patriotism that made the blood tingle, and the parade will certainly never be forgotten by its participants.

The Electrical Brigade, under Gen. Barney's special instructions, followed the latest U. S. Army drill regulations and marched past the reviewing stand with flag canes at "port arms." No others as far as observed did this, and it certainly caught the fancy of the vast crowd. The Brigade extended a quarter of a mile in serried ranks, 16 abreast.

The Interior Conduit men carried canes of gold made from shining brass armored conduit, and wore special badges. The Greeley employés had incandescent lamps at the ends of their canes. Gen. Barney, who wore a blue gold fringed sash and carried the handsome gold headed cane presented to him as superintendent of the Electric Launch Fleet at the World's Fair, did wonders with his cohorts and was heartily congratulated by everybody. He has issued special orders felicitating the Brigade on its fine showing and its success.

TELEPHONY AND TELEGRAPHY.

ELECTION RETURNS BY TELEPHONE AND TELEGRAPH.

GREAT preparations have been made all over the country for sending election returns by telephone and telegraph, and by this time most if not all of our readers in this country will have availed themselves of the service in some form or another.

In New York City and Brooklyn the Western Union Company is sending to probably 250 places the election returns received at the main office. The Postal people have a large number of engagements of the same kind, and both companies have done their utmost to get the earliest information of the issue of the election. Every important news center in the country has been covered, and the operators in all the cities and large towns have been cautioned to exert themselves election night as never before.

The Union League, Manhattan, Century, University, Calumet, Catholic, City, Colonial, West End, Democratic, Grolier, Press, Hardware, Harlem, Lambs, Lawyers, Lotos, Merchants, New York, New York Athletic, Republican, Reform, Seventh Regiment Veteran, United Service and other social clubs all have received returns. Most of these clubs have secured special wires and special operators. As fast as the returns were received they were read to the club members and invited guests.

There are thirty-five Assembly districts in this city, and in nearly all of the district headquarters operators were stationed who got the election bulletins as fast as sent into the main offices of the two big telegraph companies.

It is estimated by the telegraph companies that the number of special wires and operators contracted for is at least double the number used four years ago. All of the theatres have made arrangements for the receipt of the news, and the important bulletins were read from the stage during the progress of the performances.

Of course there were great crowds about all the newspaper offices. The display of bulletins has been made upon a scale never before attempted. Correspondents in all parts of the country have been notified to remain on duty all night and to make free use of both the telegraph and telephone wires. The amount of money spent by the newspapers in collecting the news is something fabulous, but the intensity of the popular interest in the election justifies the outlay.

Not less than 100 private citizens have made contracts with the telegraph companies for running special wires into their homes.

The Long Distance Telephone Company gave its news gratis to all subscribers. The officials of the company say that the election has furnished them with an opportunity to demonstrate that the telephone is something more than a local convenience. It happens that the Long Distance Company covers all of the States in which the fight has been the fiercest. Illinois, Indiana, Missouri, Wisconsin, Michigan, Kentucky, Tennessee—in fact, all of the States east of the Mississippi River—contain a network of long distance wires, centering in cities in which the greatest work of the campaign has been done.

Gen. Hanna, chairman of the Republican General Committee, had a direct wire from New York to Cleveland and another from Chicago, so that he could be in his office with a head piece and hear the news. Mr. Hobart had a direct wire into his house at Paterson, and the Long Distance Company kept him informed. From New York to Canton stretches a wire which ended at a desk in Major McKinley's house. As fast as the news was received at this end the secretary who had the headpiece in place in the McKinley home heard it and repeated it to the next President and his friends and neighbors.

The long distance telephone has 200 subscribers in this city. For the most part they are brokers, bankers and big merchants. The company requested all of them to be in their offices on election night. Expert operators were furnished by the company, and as fast as news came in from all the cities in the middle West and from other places it was read aloud to those in the offices.

There are 15,600 telephones in this city operated by the New York Telephone Company. Although the company thought of a scheme of giving the election news to all of its subscribers, it was found impossible to so arrange matters. The company, however, gave out the returns at all of its main stations, and special plans were made for the hotels. The local company got its bulletins from the long distance people. The latter also covered Police Headquarters in this city, a force of experts being there to tabulate the returns and get them in shape for transmission over the wires.

Special arrangements were made for telephonic election news by the New York Athletic, Manhattan and Fairfield Golf clubs. The latter is at Greenwich, Conn. Local and long distance telephones have been in use at the Republican National Headquarters in the Metropolitan Life Insurance Building, the headquarters of St. John and the Popocratic State Committee in the Bartholdi and the Republican State and County committee in the Fifth Avenue Hotel. The sound money democratic headquarters is in East Twenty-third street. Tammany Hall and the St. Cloud headquarters of the anti-Tammany Democracy also have had the local and long distance telephone service in addition to the usual telegraph facilities.

At the Bartholdi, Hoffman, Gilsey, Windsor, Majestic, Holland, New Netherlands, Plaza and other hotels every effort has been made by both the telephone and telegraph companies to give all the news of the election.

THE SUBMARINE CABLE MEMORIAL.

The proposal in England to create a memorial to the original promoters of submarine telegraphy, and the selection of the names of Sir John Pender, Sir James Anderson, and Cyrus Field for special honor, has provoked speedy and vigorous protest. Capt. Henry A. Moriarty, a distinguished officer of the Royal Navy, hastens to point out that Sir James Anderson's only connection with submarine telegraphy, from the technical pioneer point of view, was as captain of the merchant ship Great Eastern when engaged in the laying of the second and third Atlantic cables, while Sir Charles Bright and Sir Samuel Canning were the responsible persons, as regards the various early Atlantic cable expeditions of 1857, 1858, 1865, and 1866. Lord Kelvin, he says, is a sufficient witness on this point. Mr. Henry Clifford, who acted as assistant engineer both to Sir Charles Bright and Sir Samuel Canning, also writes to the London newspapers to explain that no small amount of the credit is due to Capt. Moriarty himself, who was especially selected by the Admiralty to act as navigator with both cable expeditions. At the same time he admits that the indomitable energy and perseverance of Mr. Field, as a commercial man, in raising the capital and pushing the enterprise, are entitled, undoubtedly, to admiring recognition, as are the efforts of Sir John Pender in a similar direction in England.

A TELEGRAPH LINE AMONG THE ARIZONA INDIANS.

Part of the new plan for prevention of raids by the Apaches includes the construction of a military telegraph line in Arizona, to be built by the Signal Service Corps.

A single line of wire supported on iron telegraph poles, will comprise the proposed work. The material to be used, now on its way to Bisbee, is what is left of the old military line between Carthage, N. M., and Ft. Stanton, N. M., a distance of 90 miles. Part of this material was used to erect the line put up some time ago between Cedar Springs and Mammoth, Ariz. The Indians rarely resort to cutting of telegraph wires and consequently the only danger to lines is the destruction of the poles and insulators. Campers and overland travelers in that country where wood is so scarce might be tempted to cut down the wooden poles for use in burning. Consequently iron poles will be employed. It has always been a favorite diversion of humorously inclined cowboys to try their marksmanship by shooting down the glass insulators. There is an act of Congress which makes this sport an offense against the Federal government, and Capt. W. A. Glassford, U. S. A., will attach to his iron telegraph poles linen notices of the law in regard to insulators, the same to be printed in both English and Spanish so that everyone who runs, or shoots, may read.

From Bisbee the material will be hauled by mule teams along the proposed line. The reconnaisance was made by Lieut. Averill of the Seventh cavalry a few weeks ago. Heliographic stations will be established in the surrounding country, as they may be deemed necessary. By means of them the whole territory can be kept under the eye of the government.

PARIS WIRES LONDON VIA NEW YORK.

An incident of the general demoralization of the telegraph lines by the recent gales in Europe was the exchange of messages by commercial cables between Paris and London by way of New York. The route followed was in the underground line from Paris to Havre, ocean cables from Havre to New York, and ocean cables from New York to Weston-

Super-Mare. It is noteworthy that, with the exception of the short line between Weston-Super-Mare and London, the messages completed their long transits by wires entirely removed from the disturbance of the elements.

ELECTRIC LIGHTING.

ELECTRICITY AT ST. ELIZABETH'S U. S. HOSPITAL FOR THE INSANE.

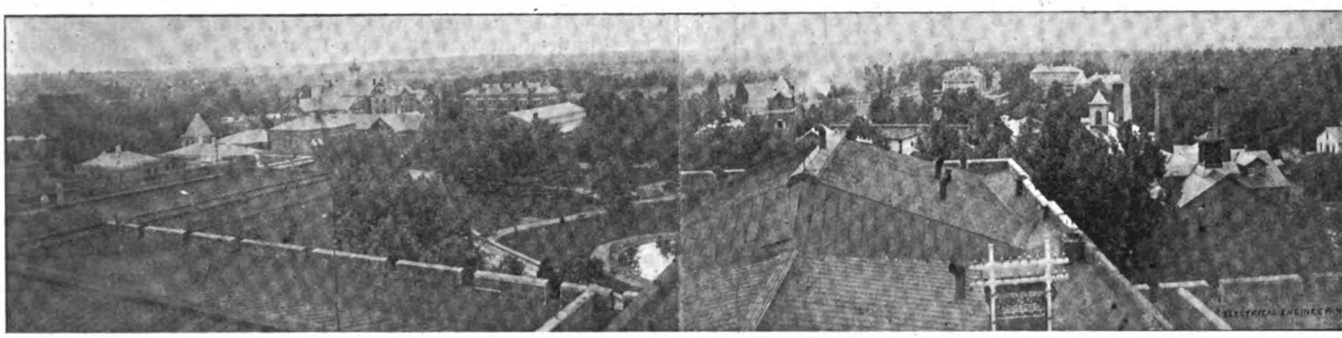
If you look off from the West Terrace of the Capitol at Washington, over the mass of green foliage that covers the city, past the Navy Yard and across the Anacostia River—a branch of the Potomac—you will see upon a commanding height clothed in verdure, and itself half enshrouded, half revealed, the long majestic Administration Building of St. Elizabeth's, the Government Hospital for the Insane. Beneath its shadow, and in the fifty other buildings that cover the beautiful grounds and complete this retreat for the mentally infirm, two thousand three hundred people are provided for.

To reach the asylum from the city is something of a journey, involving crossing the river and climbing a road which ascends seemingly interminable hills. At the top, however, you find a level bit of table land, and here you are confronted by the usual high brick wall, which does not prevent some patients from "eloping," as the authorities term it; for they spend hundreds of dollars annually in rewards for reclamation.

If your business is satisfactory to the lodge warden, you are passed, and the great iron gates clang behind you. From the moment of hearing the clang you are conscious of a watchful care, which surrounds everybody and everything, extending even to the grounds, which are beautifully laid out and tended. Velvet lawns stretch away in all directions, dotted with groups of magnificent trees, and illuminated by artistic flower beds in bright hues. Broad driveways and paved walks extend in graceful curves through the groves and past trim but substantial buildings. The main walk disappears in shrubbery, above which can be seen the majestic proportions of the Administration Building.

The Administration Building faces the city of Washington and is almost a thousand feet long. It contains the offices and quarters of the resident staff, and in its wings the temporary receiving ward, and a female ward. From its front, on the brow of the hill, a magnificent view of the environs of the Capital is obtainable. From its roof, whence our bird's eye view was taken, the extent of the institution can be perceived. The grounds cover nearly eight hundred acres, and there are fifty-one buildings on them.

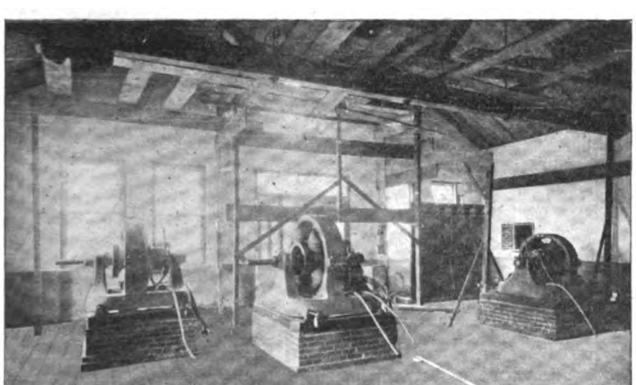
The hospital was established by act of Congress, March 3, 1855; and it is managed by a board of nine citizens of the District of Columbia, appointed by the President. The immediate government is in the hands of a resident superintendent, who is the responsible head of the whole—medical, financial and executive; feeding, clothing, housing, and attending professionally a family of two thousand sick people, directing the disbursement of hundreds of thousands of dollars annually, and of necessity on the qui vive all the time to keep abreast of the times in all his manifold occupations. The present incumbent is Dr. W. W. Godding, a man of more than national reputation, of the highest possible professional standing, wide attainments, wonderful executive ability, and above all of a very genial and lovable nature. He is assisted by an able corps of physicians, but where the responsibilities are so vast unity of head becomes a necessity, and on the judicious exercise of his individual responsibility the success of the hospital depends. The value of the property is now over a million dollars, and the annual expenditures are not far from a half a million.



BIRD'S EYE VIEW OF ST. ELIZABETH'S, GOVERNMENT INSANE ASYLUM, WASHINGTON, D. C.

The buildings with their patients are divided into six groups, viz.: 1, the Central Male, with 19 wards, 400 inmates; 2, the Female, with 20 wards, 375 inmates; 3, the Criminal and Homicidal, with 8 wards, 120 inmates; 4, the Male Chronic, with 13 wards, 500 inmates; 5, the Southern or sick, with 9 wards, 200 inmates; and Goddingscroft, a settlement of 50 mild cases who are employed as farmers. Each department is under charge of its respective physician, with head nurse, nurses, keepers, helpers, etc.

Up to a comparatively recent date the institution had made small use of electricity. As far as therapeutic uses go next to nothing had been done and in respect of the practical applications nothing at all. The many buildings have been lighted by gas, to supply which the hospital has its own gas works. The cooking, which of course is on a very large scale, has been done by steam or on ranges. Heating has been by steam as far as possible. The mechanical treatment of patients, such as massage, has been by hand. The stacks of the battery of heating boilers, of the gas house and the main kitchens, may be seen at the extreme right of the bird's eye view. The system of heating has been very complete of its kind, and in

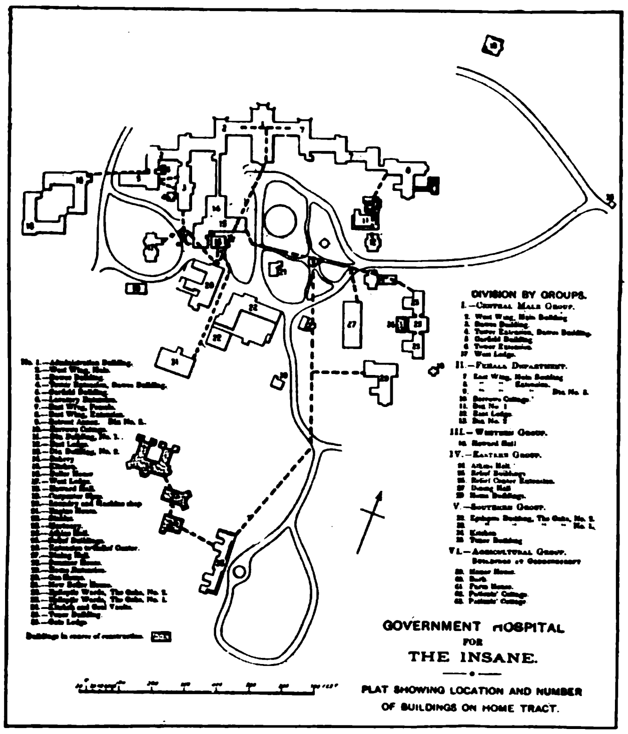


THE DYNAMO ROOM.

THE POWER HOUSE.

connection with this may be mentioned what is the most striking feature of the institution from an engineering standpoint. Every group of buildings, near and far, shown in the general plan view is connected with all the other groups, and every building with all the others by an elaborate series of underground galleries, or tunnels, indicated by dotted lines on the plan below.

These tunnels are necessarily miles in extent, and as seen in



THE GOVERNMENT INSANE ASYLUM AT WASHINGTON.—TUNNEL CONNECTING BUILDINGS SHOWN IN DOTTED LINES.

the engraving, they are all (with one exception in the old building), well lighted and ventilated. The tunnels are arched with brick and masonry, paved with brick and flags, and have narrow gauge tracks for the accommodation of small hand cars which are used for the transportation of supplies. Most of the food prepared at the main kitchen is distributed in this way. The steam pipes, well jacketed, are carried upon cast iron brackets let into the walls of the tunnels, and are carried to all the buildings. This construction may be seen on the left of the tunnel picture. Gas and water pipes are carried on the ground, as shown. It is possible, through the tunnel system, to traverse every building in the grounds, a half day's journey, without passing above ground.

The water supply of the institution is obtained from artesian wells located in the lower part of the grounds, near the river. On the shore a pumping station is located, containing the boilers and pumping engines, a large and small pair, which raise the water from the river level to a tank in the attic of the Administration Building.

For a long time the management of the institution have realized that in electricity a potent agent lay idle, and active steps have been taken during the last year to remedy the defect. More than a year ago a complete telephone system was installed. The Central office is located in the pharmacy, on the main corridor of the Administration Building, and from there the circuits, which are metallic, are carried up to the roof in a Kerite cable, whence they are carried on the buildings and poles through the grounds. The instruments are microphones, and the outfit is of the most modern type. The materials were furnished by Kennedy & Du Perow, and the work of installation done by J. U. Burket, of Washington. The scheme is to connect every ward and department directly with the superintendent and head quarters, as well as with each other. In addition there are telephones in the pumping station, the dynamo room, and the stables, so that everything is under direct control.

Early in 1895 bids were opened and contracts awarded for boilers, engines and dynamos, and the work of constructing and installing a modern electric lighting system undertaken. It was felt that this was a work of such magnitude, on account of the difficulties to be encountered and the conditions to be met, that it would be unwise to let the construction work out, and so lose control of the work in point of time and manner of working. It was decided to retain an engineer, and do all construction in the buildings by day labor. This gave the added advantage of enabling the institution to employ many of its inmates who are more or less skilled mechanics, and are tractable. In pursuance of this, Mr. Michael J. O'Donnell, for a long time the manager of the Potomac Light and Power Company, was engaged, and under his able direction the work has now progressed so far that about six thousand lights are installed, and the plant is in such shape that it can be started up at any time.

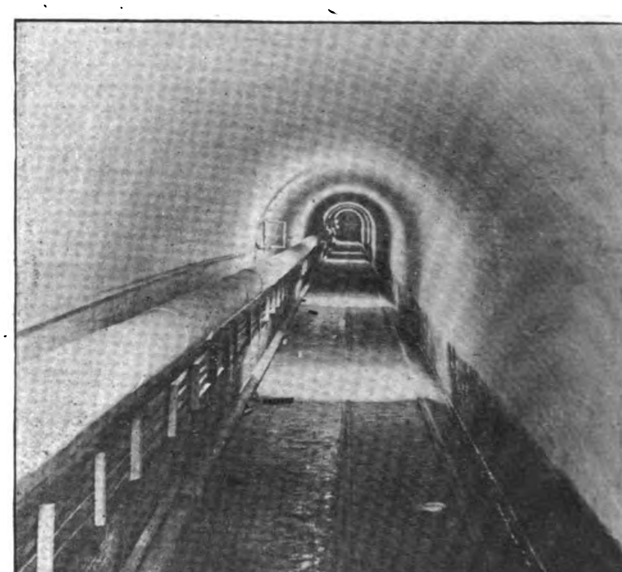
In laying out the wiring plans, it will be apparent that peculiar conditions had to be met. It was not sufficient to satisfy the insurance inspectors touching the character of the work, but it was demanded at the outset that the risk of fire should be absolutely nil, that all wires and fixtures should be beyond the reach of meddling or mischievous patients, and that the work should be done without disturbing the regular routine of the institution. In case of fire nothing on earth could control 2,000 lunatics.

Under these conditions Mr. O'Donnell went to work, and although more money has been expended than the most liberal estimates provided for, it is believed that the result is a system which can scarcely be equalled for thoroughness and perfection of material and workmanship in the country. Two hundred and twenty-one thousand feet of Kerite wire have been used.

The three-wire system has been employed. A new dynamo house was built of brick, one story high, 60x100 feet, which contains the engine room and a boiler room, separated by a space containing the condensers. Our engraving shows a view of this taken before it was finished, with the forty-foot iron stack on the ground.

The boilers so far installed are two in number, and were furnished by the E. Keeler Company, of Williamsport, Pa. They are of horizontal tubular type, built to specifications specially drawn for this work. They are tested to 150 pounds, and are calculated to furnish 400 horse-power. The battery is expected to be duplicated before the plant is fully in operation.

There are two pair of dynamos and two engines. The engines are Armington & Sims, high speed, cross compound, horizontal, condensing, with two cylinders, opposite cranks, automatic cut-off; and are connected to the dynamos by rope drives of four-strand manilla ropes. The cylinders of the larger engine are 13 and 20½ inches diameter, with fifteen-inch stroke, making 265 revolutions per minute, and giving 200 indicated horse-power. The two rope wheels for this engine



TUNNEL CONNECTING BUILDINGS OF GOVERNMENT INSANE ASYLUM, WASHINGTON.

are 74 inches on the pitch line and have each eleven grooves for ¾-inch rope.

The smaller engine has 10½ and 16½-inch cylinders with 12-inch stroke and makes 285 revolutions per minute with 100 indicated horse-power. The rope wheels for this engine are 74 inches on pitch line and are scored for six ropes. Stratton separators and Baird steam traps are used, with Davidson jet condensers.

There are two pair of dynamos, General Electric multi-polar compound wound, self-regulating. The larger pair give 100 kilowatt and the smaller pair 50 kilowatt at 125 volts. This part of the plant is also to be duplicated. The larger pair have rope wheels 30 inches in diameter, the smaller 17¾.

As all the buildings are grouped more or less regularly on a level table land, the scheme of distribution is simple. At the power house a slate switchboard is provided, with separate cut-outs, ammeters and voltmeters for the dynamos. From this switchboard eleven No. 0000 bare copper feeders, three No. 6 pressure, and two No. 8 extra wires, at present used for telephone, are run on poles up the hill 2,700 feet to the main distributing station at X, back of the Administration Building, in the plan. Here is located the distributing switchboard, of marbleized slate, equipped with cut-outs, section switches, Weston instruments, etc. It will be noted that this board is set out in the middle of the station. It has a space 10 x 12 ft. behind, and a chamber 10 x 4 x 6 ft. built under the board, allowing ample clearance for the cables and wires, and giving free access to everything at all times. Access to the lower chamber is by a flight of stone steps. From this chamber the cables pass into the main tunnel under the Administration Building, and thence branch into the other tunnels, as indicated in dotted lines on the plan, to their respective groups of buildings. The main tunnel was found damp in some places, necessitating the use of lead-covered cable.

The total Kerite cable used was 12,742 feet, the largest having 860,000 circular mils. The cable runs may be seen at the left of the tunnel picture, where they are shown in moulding. The lead-covered cable was carried on iron brackets let into the brick work. At each branch tunnel and wherever the tunnels enter the buildings branch, or junction, cut-outs of the standard G. E. type for three-wire system are used. The tunnels are lighted by sixteen candle-power lamps at intervals of 100 feet, and wherever these lamps are placed on the run of a cable the necessary feeders are run back to the last junction cut out, no taps being allowed on any cable.

From the junction boxes in the tunnel entrances the main feeders for each building are run through special flues. On each floor are located small switchboards fitted with cut-outs, fuses, etc. All these boards are of slate or hard wood of special design and are set in recessed spaces in the corridor walls with flush doors fitted with Yale locks. The flues open into the recesses behind the boards, and the whole construction is such that unauthorized interference without the aid of tools is impossible.

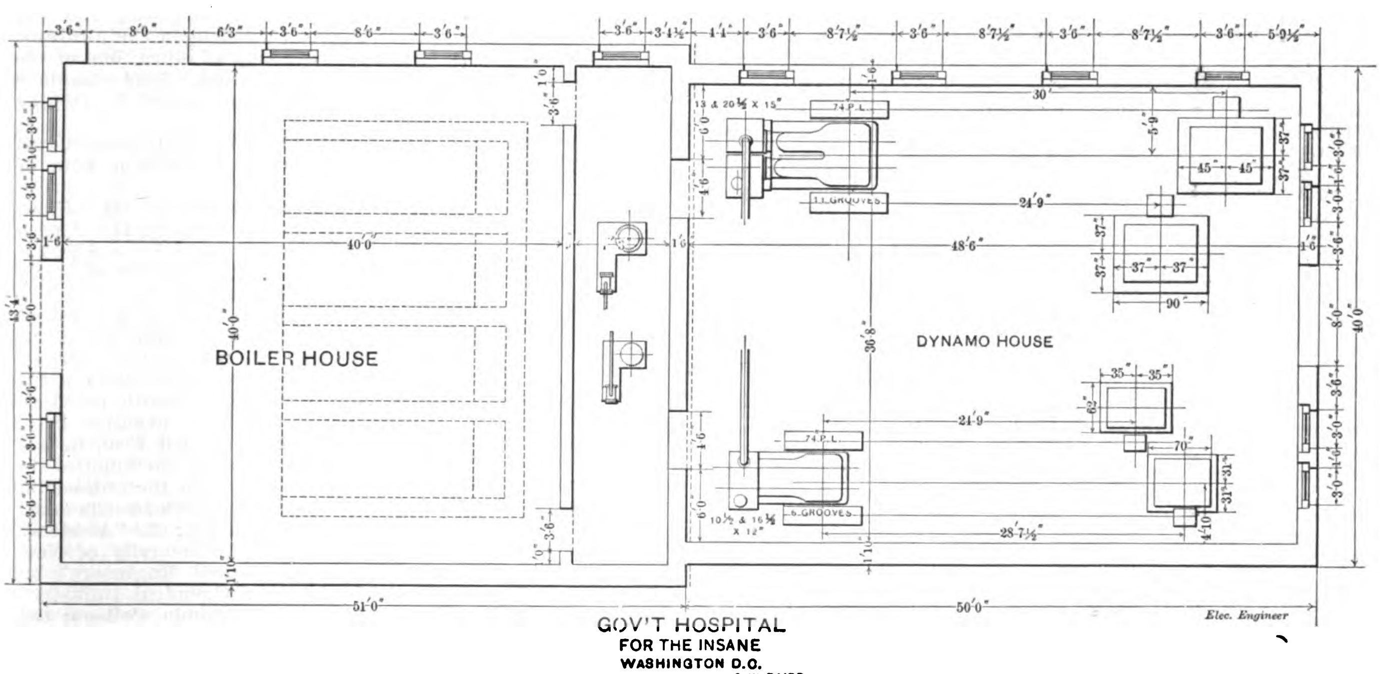
In wiring the buildings concealed work was done of necessity in all but the Administration Building. And in nearly all the buildings the work was performed under the greatest difficulty. In the Administration Building capped moulding was used, of which 30,340 feet was required. In one or two of the female wards it was found possible, because of the height of the ceilings, which were fireproof arches, to use moulding. In these cases stout bridge pieces were wedged firmly across the narrow arches between the webs of the girders and above the flanges and to these the moulding was secured by screws. In all the buildings now occupied where concealed work was done it was found necessary to cut the plaster, and all the wires in addition to their heavy insulation were encased in Circular Loom flexible conduit. In wiring these buildings, 15,532 porcelain tubes were used and 62,000 feet of Circular Loom tube.

In wiring the new buildings, which were under process of construction, a system of floor conduits was adopted which was unfortunately precluded in the older buildings. These buildings are fireproof, the floors being hard wood over iron and masonry arches. Upon the masonry in a bed of cement were laid shallow conduits with slate sides top and bottom. At convenient points, such as outside each room door, portions of the floor are made removable by being screwed down. Under these, pockets are formed, the slate covers of which are loose, and from these pockets the wires in their Circular Loom tubing can be readily drawn or pushed into place, the interior of the conduit being comparatively smooth. In all cases where joints are made in the Circular Loom covered wire the joint is taped and the tap wire taped to the other closely and the joint and taped portion drawn back into the tubing, an extra piece of split tube being then placed around the whole and taped over.

Throughout the entire system each floor is balanced at the floor switchboard and each building is balanced by itself. As those lamps which are to burn all night are readily ascertained, and as the entire system is organized to be worked as a matter of routine by the attendants, it has been possible to balance both the maximum and the minimum loads once for all. Thus the attendant at the proper hour by throwing the switches on the floor switchboard can cut out all but the night lights. The telephone connections between the wards, the distributing station, the dynamo room and the superintendent's office render the whole a perfect machine under perfect control.

Most of the fixtures are ceiling clusters, out of reach, as they are never to be touched except to replace lamps. All of these appliances have been made to order from original designs by the well known firm of Kennedy & Du Perow, of Washington. The chandeliers, all small switchboards, cut-outs, etc., as well as all the wire and cables and the Circular Loom tubing were furnished by the same firm, and in all the complex dealings which were necessitated during the progress of the work there does not seem to have been a hitch.

The lighting system being in operative condition it is the intention of the superintendent to introduce electrical appliances wherever possible, $6,000 for electric fans alone being estimated for next summer. Incandescent arc lamps are to be used for lighting the grounds, electrically heated warmers are to replace the steam tables to keep the food from cooling while serving. It is only a question of time when the current



PLAN OF ENGINE AND BOILER HOUSE, GOVERNMENT INSANE ASYLUM, WASHINGTON, D. C.

will be used for all sorts of purposes in the wards. Small motors have been found very convenient to run the massage machines now coming into general use, and as the 110 volt current has demonstrated its ease of manipulation for therapeutic purposes, the proper apparatus may be carried to any ward for use without a battery. Thus electrically lighted endoscopes, X-ray apparatus and even the bath cabinets lined with incandescent lamps devised by Dr. Kellogg, of Battle Creek, described in The Electrical Engineer of September 30, can be used where required without trouble.

SOCIETY AND CLUB NOTES.

M. MOISSAN ON THE ELECTRIC FURNACE.

THE MOISSAN BANQUET.

On the evening of October 27, M. Henri Moissan delivered a lecture on "The Electric Furnace" at the College of Physicians and Surgeons. This lecture was given by invitation of the New York Academy of Sciences, The New York Section of the American Chemical Society, The American Institute of Electrical Engineers, The College of Pharmacy of the City of New York, and the New York section of the Society of Chemical Industry.

After a most enthusiastic welcome from the audience which completely filled the hall, M. Moissan introduced his subject by pointing out that while the carbon compounds have been studied with great care by organic chemists during the past fifty years, the study of the different stages through which carbon passes had been comparatively neglected. In his endeavors to obtain pure carbon, the ordinary amorphous carbon, lampblack, containing from 10 to 15 per cent. of impurities, he had found it necessary to use very high temperatures and had succeeded in obtaining one form of pure carbon, graphite. High temperature alone, however, would not yield the crystallized form of carbon, diamond. He set to work to find out the composition of diamonds by reducing some to ashes. In all, whether they came from the Cape of Good Hope or from Brazil, he found iron, save in one very pure green hard stone from Brazil. By the study of the nature of the ground and of the geological formation in which Cape diamonds are found, he found that the earth, besides graphite and microscopic diamonds, always contained granite. Granite is the product of great pressure, and this fact led him to the idea that diamonds might also be obtained by pressure. As cast iron increases in volume in passing from the liquid to the solid state, he was led to believe that if an element of carbon were enclosed in a globule of cast iron that was cooling it would be subjected to the requisite pressure.

In order to obtain a heat sufficiently great and at the same time to be able to measure it, he devised the simple form of electric furnace with which the experiment last Tuesday was performed. It consists of two lime or chalk bricks, the lower one about eighteen inches square and a foot deep, the upper one about six inches deep. In the lower one is hollowed out an elliptical hole to contain the crucible, while two carbon electrodes pass from the cavity to the exterior, where they are connected with the source of current. The upper brick serves for a cover. M. Moissan first sprinkled the cavity with magnesia in order to prevent the formation of calcium carbide. He then placed in it the graphite crucible, into which he had put some soft iron filings and charcoal, covered it with the top brick, and turned on the current.

In three minutes the indicator showed a temperature of 2,500° Fahrenheit. The chalk was boiling and flaming before the eyes of the audience when M. Moissan put his hand on the top brick and kept it there to show that the heat did not come through.

At the end of ten minutes the process was complete. M. Moissan lifted the top with his hands, though its under side was white hot, and after holding it up for a while dropped it into some water.

The crucible he took out with tongs and also dropped into cold water. He explained that the first time he had cooled the mass in that way he had taken every possible precaution, expecting an explosion, but that after repeating the process three hundred times without an accident he felt that the audience was safe.

On breaking the crucible he took out an ingot the size of a bullet and explained the processes by which the iron would have to be eliminated in order to get at the crystallized carbon that was probably within it. The diamond will have no commercial value, as the largest he has succeeded in making is only one millimeter in diameter.

The form of the crystals varies according to the method used in cooling. When water is used the diamond is often full of black specks which detract from the value of a stone. M. Moissan was delighted to discover these spots, as they proved to him that he was following in the track of nature.

When molten lead is used to cool the crucible the crystal takes the shape of a small rectangular figure, sometimes with the sharp edges rounded, but when mercury is used the crystal is a regular octahedron. Some of the last, when exposed to the air, split, as has happened to some of the diamonds found at the Cape. This was an additional proof to M. Moissan that diamond is produced under strong pressure.

His conclusion is that at the ordinary temperature carbon does not liquefy, but changes at once from a solid into a gas, always taking the graphitic form, and that only under pressure does it take the "liquid" form, diamond.

The rest of the lecture was taken up with a hurried review of the other products obtained by M. Moissan by means of the electric furnace, metallic chromium, molybdenum and tungsten. These, with many of the oxides supposed to be irreducible, which have yielded to the furnace, he had on the table in glass jars. He spoke particularly of the excellent qualities of molybdenum steel.

He ran over the properties of the long list of carbides discovered by him, and produced acetylene gas before the audience by putting some lithium carbide into a jar of water, which thereupon bubbled up, after which he touched the gas off with a match, producing a brilliant flame. It smoked so much that after two minutes the jar was removed, and during the rest of the evening smoky filaments kept falling upon the auditors.

The last experiment was the volatilizing of silica, one of the latest of M. Moissan's scientific achievements. This was done in the electric furnace, a glass globe placed over it catching and condensing the vapors.

At the end of the lecture, which was frequently interrupted by applause, Prof. R. Ogden Doremus proposed a vote of thanks to the lecturer.

M. Moissan was assisted in his experiments by Mr. C. O. Mailloux, who was delegated for that purpose by the American Institute of Electrical Engineers. The Edison Electric Illuminating Company also kindly loaned a number of heavy rheostats and other apparatus for the occasion.

As an acknowledgment of the lecture and as a farewell mark of esteem, a banquet was given to Prof. Moissan at the Hotel Waldorf on Wednesday evening, when about 50 sat down to table. Prof. R. Ogden Doremus, of the College of the City of New York, presided, and Mr. T. C. Martin acted as toastmaster. To the toast of the guest of the evening, Prof. Moissan replied in the clear, terse and beautiful French that made his lecture so enjoyable, and he also participated in one or two of the discussions that arose as to the outlook in the chemical and electrical arts. The "American Chemical Society" was responded to by Dr. C. B. Dudley; the "Academy of Sciences" by Prof. Morris Loeb of the University of New York; the "American Institute of Electrical Engineers" by Prof. F. B. Crocker, and the "Society of Chemical Industry" by Prof. C. F. Chandler, both of the Columbia College; the "College of Pharmacy" by Dr. Wm. Jay Schieffelin; the "Civil and Mechanical Engineers" by Dr. C. E. Emery, president of the New York Electrical Society; the "Expert and Allied Sides of the Chemical Arts" by Dr. A. R. Ledoux; "Technical Literature" by Dr. Park Benjamin, and the "Chemical Manufacturing Industries" by Mr. I. J. R. Muurling. Among those subscribing to the banquet, and nearly all of whom were present, were E. D. Adams, Edward Weston, C. O. Mailloux, Dr. S. Sheldon, Prof. C. A. Doremus, Herbert Laws Webb, W. Diestel, W. McMurtrie, B. Lillard, Dr. C. T. Hutchinson, Dr. Louis Duncan, J. W. Lieb, Jr., H. Ward Leonard, W. D. Edmonds, E. N. Dickerson, Dr. P. T. Austen, Prof. A. R. Leeds, Prof. A. H. Mason, D. O. Haynes, publisher of the "Pharmaceutical Era," G. F. Kunz, the gem expert of Tiffany's, and many other well known men.

Prof. Moissan, accompanied by his wife and son, sailed for France on Saturday.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION.

Mr. C. M. Goddard, secretary of the above association, has issued a circular letter announcing the meeting which is to take place in New York on Dec. 8, and asking for suggestions as to any desirable changes in the rules for electric light and power wiring.

INTERNATIONAL ASSOCIATION OF FIRE AND POLICE TELEGRAPH SUPERINTENDENTS.

The above association formed recently with Mr. Frank C. Mason as president, has already issued its first report, prefaced by portraits of the officers. Mr. Ralph W. Gordon, vice-

president of the Gordon-Burnham Battery Company, writing to the president says: "I enclose herewith my check for $25 in payment of my dues as an associate member of your association. After conversing with many superintendents throughout the country, I am confident that the future success of the association is now assured." This is but one out of many such letters of encouragement and good will.

THE OHIO ELECTRIC LIGHT ASSOCIATION.

The annual meeting of the Ohio Electric Light Association was held at Springfield, Ohio, on Oct. 13. The meeting was a most successful one in every way; the attendance being good and the discussions which occurred most interesting and helpful. The next annual meeting of the association will be held in Cincinnati, on the second Tuesday in October, 1897. The officers elected for the coming year were as follows: President, John I. Beggs, Cincinnati; vice-president, Geo. S. Long, Bowling Green; secretary and treasurer, Sam'l Scovil, Cleveland.

PERSONAL.

DISMISSAL OF THE CHARGES AGAINST SUPT. SMITH OF THE NEW YORK FIRE TELEGRAPHS.

FOR some time past, Mr. J. Elliot Smith, the superintendent of the Fire Telegraph service of New York City, has been on trial before the Board of Fire Commissioners, on charges of fraud and incompetency. A large amount of evidence was taken, and counsel were employed on both sides. The Commissioners have dismissed the charges, and Mr. Smith, who was suspended, has been reinstated.

President Sheffield said that as all the law points had been disposed of at a former meeting, a decision would be made on the questions of fact in relation to the charges that had not been disposed of. Secretary Jussen read the charges and they were acted upon separately.

On the first charge it was alleged that Mr. Smith fraudulently prepared contract specifications so that no one could fully understand them, and for the purpose of giving the Standard Underground Cable Company an advantage over other bidders. Commissioner La Grange said that the city had lost $100,000 by Mr. Smith's method of drafting specifications, but when a vote was taken he cast his with the other Commissioners, and the charge was dismissed.

The second charge was that Mr. Smith conspired with the Pierce & Jones Company to permit it to furnish supplies to the department at exorbitant rates. Commissioner La Grange voted to sustain the charge. Commissioner Sturgis and president Sheffield voted to dismiss it on the ground that as there was no clear proof of fraud, it must be assumed that Mr. Smith acted in good faith within his discretion. The charge was dismissed.

On the third charge, alleging that Mr. Smith bought supplies from the Standard Underground Cable Company at exorbitant rates, the vote was the same as on the second charge, the commissioners who voted to dismiss saying that the prices paid were reasonable under the circumstances. The charge was dismissed.

Commissioner La Grange voted to sustain the fourth charge, which alleged conspiracy with many persons to defraud the city by means of exorbitant prices. The charge was dismissed by the votes of President Sheffield and Commissioner Sturgis. The fifth charge, alleging incompetency in preparing contracts for underground cable work thus preventing intelligent bidding; the sixth charge, which alleged failure to properly inspect and keep a record of underground cable work; the seventh charge alleging a conspiracy with the Pierce & Jones Company to compel charitable institutions to connect with the fire alarm system through the Pierce & Jones Company, were all dismissed by the votes of President Sheffield and Commissioner Sturgis, Commissioner La Grange voting to sustain.

In the eighth charge, Mr. Smith was alleged to be incompetent in having permitted the alarm system to deteriorate, thus causing fires. Commissioner La Grange, in voting to sustain the charge, said that the New York fire alarm system was inferior to those of other cities in this country. The other commissioners admitted that certain features were not as perfect as they should be, but refused to hold Mr. Smith responsible for them, and dismissed the charge.

The charges being disposed of, a motion to reinstate Mr. Smith was made and carried, Commissioner La Grange again voting in opposition to the two other commissioners.

MR. R. R. BOWKER, vice-president of the Edison Electric Illuminating Company, of New York, has found time recently for two very interesting literary productions, one being an instructive paper on "Electricity" in the October "Harper's Magazine," and the other some personal recollections of George du Maurier, in the New York "Times," of Sunday, Oct. 25. Both are extremely well worth reading.

MR. F. R. UPTON, who is so well known in the electrical field as manager of the Edison Lamp Works, and who is now manager of the sales department of the huge McKeesport Tube Works, near Pittsburg, was a recent visitor to New York, where many old friends were delighted to see him and to exchange news. Mr. Upton looks well and is very busy.

OBITUARY.

MONROE GREENWOOD.

The death is announced of Mr. M. Greenwood, the president of the California Electrical Works and vice-president of the Sunset Telephone and Telegraph Company, after a week's illness, at San Mateo, California. He was sixty-eight years of age. He was a Mississippian, and went to California in 1851. Two of his sons hold responsible positions in the Sunset Company.

LETTERS TO THE EDITOR.

"SILVER TO GIVE AWAY."

Your editorial in issue of Sept. 30, 1896, entitled "Silver to Give Away," based on matters contained in article copied from "Engineering and Mining Journal," in relation to plant of Anaconda Mining Company, of this city, is evidently written, as editorials too often are, without proper comprehension of the subject. It is a fact known to "Engineering and Mining Journal" and to all persons familiar with the Silver Bow mining district, that neither the Anaconda Company nor any other of the large copper companies could work its mines at a profit if it were not for the by-products of silver and gold, and conversely the silver and gold could not be mined without the copper. This same condition applies to most of the large copper producers of the United States, outside of Lake Superior district. Hence the large development of the electrical industry, made possible by the reduced price of copper, is almost directly due to silver, the greatest by-product. Your deduction as to possible increase of production is an exaggeration beyond the practical in mining, and can only make one laugh who has some knowledge of mines and the mining country, but may be swallowed whole by some of our more benighted brethren in the electrical field.

D. S. SIMPSON,

Butte, Mont., Oct. 23. Rocky Mountain Bell Telephone Co.

(None of the figures were ours, but were furnished by the expert of the Anaconda mine, who ought to know what he is talking about. It was shown that the company with a capital of $5,000,000 paid a dividend of $750,000 last May; another being now due, or paid. The company gets practically the same price for its copper as the Lake Superior mines, and has all its silver as a "side show." Mr. Morrell, speaking for the silver and copper mines of the West, said that they stand to make yearly $36,000,000—out of the Government—if the free coinage of silver went through. If this makes anybody "laugh" it does not make us do so by any means.—Ed. E. E.)

LEGAL NOTES.

DAMAGES FOR VIBRATION BY LIGHTING PLANT.

The case of T. J. Preston & Company, linseed oil makers, Newark, N. J., against the Newark Electric Light and Power Company, to recover $100,000 for damages to Preston & Company's building and business by the the vibration of the machinery in the company's building, ended recently in Judge Depue awarding plaintiff $5,000. By agreement a jury was dispensed with and the case submitted to Judge Depue, as the principal contested points were of a legal nature.

THE BROOKLYN SUBWAY COMMISSION went out of existence November 1. It was created in 1892, for a term of four years to put the Brooklyn wires underground, but there are more wires than ever overhead and all efforts to extend the life of the commission have failed.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Alternating Current:

ALTERNATING FROM DIRECT CURRENTS.—By Lieut. F. Jarvis Patten. Paper read before the National Society of Electro-Therapeutists. Illustrated description of a simple device for transforming direct into alternating currents of a pure sine curve.—"Elec. World," Oct. 17, '96.

EXPERIMENTAL STUDY OF INDUCTION PHENOMENA IN ALTERNATING CURRENT CIRCUITS.—By F. E. Willis. Results of some experiments made upon circuits containing resistance, self-induction and capacity.—"Phys. Rev.," Sept.-Oct., '96.

Central Stations:

CENTRAL STATION AT ZURICH.—By M. Jacquine. A water power plant running 10 dynamos of about 150 h. p. each. Alternating current is sent to substations where the current is rectified by means of the Pollak rectifier and utilized to charge storage batteries.—"L'Eclair. Elec.," Sept. 12, '96., and subsequent issue.

THE NEW STATION OF THE LONG ISLAND CITY ELECTRIC ILLUMINATING AND POWER COMPANY.—Station consists of four 400 h. p. boilers, working on a pressure of 125 pounds; there are two engines. There are eight 50-light T.-H. arc machines running from countershafting, two 80-light Brush machines, wound on the three-circuit plan; two Westinghouse two-phase generators form the machinery for power purposes.—"Elec. World," Oct. 17, '96.

Electro-Chemistry:

IMPROVED METHOD OF ELECTRO-PLATING.—Articles are placed in large quantities in a revolving container, which is suspended or supported within the electrolytic bath, and during the time deposition is taking place is subjected to a rotary movement varying from fifteen to fifty revolutions per minute.—For details see "Scien. Am.," Oct. 10, '96.

ELECTRIC SMELTING FURNACE.—Illustrated description of a furnace patented by Joseph A. Vincent, of Phila.—"Iron Age," Oct. 8, '96.

Electro-Physics:

VELOCITY OF ELECTRIC WAVES.—By Clarence A. Saunders. Author gives the history of the subject and then follows it up with a careful set of researches.—"Phys. Rev.," Sept.-Oct., '96.

ON A COMPLETE APPARATUS FOR THE STUDY OF THE PROPERTIES OF ELECTRIC WAVES.—By Jagadis Chunder Bose, M. A. Paper read before the British Assoc. for Adv. of Science.

MUTUAL INDUCTION IN PARALLEL DISTRIBUTING CIRCUITS.—By Dugald C. Jackson. Writer shows that the mutual inductance of any two parallel circuits of indefinitely great length may be easily calculated, provided the distances apart of the different wires composing the circuits are known.

Isolated Plants:

ELECTRIC INSTALLATION OF THE MOHAWK BUILDING, CLEVELAND.—This plant consists of three 60 x 16 horizontal, tubular boilers, three Ball engines, working at 90 pounds' pressure, to which are directly coupled three 25 k. w., 115 volt, 240 ampere dynamos.—"Elec. World," Sept. 19, '96.

SMALL ELECTRIC LIGHTING PLANTS FOR COUNTRY HOUSES.—It is shown in a short article how successfully small isolated plants may be run in country houses, by means of oil engine, dynamo and accumulator.—"Lond. Elec. Rev.," Sept. 18, '96.

Lighting:

LIGHTHOUSE ILLUMINATION.—By C. S. Du Riche Preller. An elaborate and valuable series upon coast and lighthouse illumination in France.—Abstracted from "Engineering" in "Progr. Age," Oct. 1, '96.

LIGHTING BY ACETYLENE.—By G. Pellissier. Illustrated description of electric furnaces used at Spray and Niagara; also special design by Bullier.—"L'Eclair. Elec.," Sept. 12, '96.

Magnetism:

ON THE MAGNETIC BEHAVIOR OF ELECTROLYTIC IRON, NICKEL AND COBALT.—By W. Leick. Author obtained his deposits from the following three solutions: 1, Ferrous sulphate; 2, Ferrous chloride; 3, Iron ammonium sulphate.—Results obtained from these deposits are stated in tabular form in Lond. "Elec.," Sept. 18, '96.

Measurements:

MEASUREMENT OF POWER IN TWO AND THREE-PHASE CIRCUITS BY MEANS OF WATTMETERS.—A short article explaining methods of connecting and reading results.—"Elec. World," Sept. 26, '96.

AN ARRANGEMENT OF RESISTANCE BOXES.—A number of resistance coils shown in skeleton form.—"Electricity," Sept. 16, '96.

Mechanical:

HORNSBY-AKROYD OIL ENGINE.—Description of engine with illustrations.—"Can. Elec. News," Oct., '96.

Mining:

ELECTRICITY DOWN A COAL MINE.—Illustrated description of the Abercanaid Colliery, England.—"Lond. Elec. Rev.," Sept. 18, '96.

Power Transmission:

SHAFT AND ELECTRIC TRANSMISSION.—Diagrams presenting results of power tests made in a factory. The first shows the estimated friction loss in the engine, the loss in shafting, belts, etc., and the useful work performed during a working day. The second indicates the same loss in the engine, the constant losses in the dynamo, the variable losses in the motors and line, and the useful work. In the first case the average indicated horse-power was 44.1 and in the second 25.7. The total loss in the first case was 31 horse-power and in the second about 13 horse-power.—"Iron Age," Sept. 17, '96; "Railway Rev.," Oct. 3, '96.

LIGHTING AND POWER COMBINED.—It is shown that in many cases economical results are obtained by running lighting stations in connection with railways, and furthermore it is shown that advantages may be derived from running storage batteries in connection therewith for two reasons; first, batteries going down hill may charge; secondly, the steam engine runs more uniformly.—"Die Elektrizität," Sept. 5, '96.

ELECTRIC TRANSMISSION AT NEUCHATEL.—Transmission of power is accomplished by means of three-phase currents, while for lighting the single-phase current is employed. Detailed description in "Elektrotechn. Anz.," Oct. 1. '96.

ECONOMIC USE OF ELECTRIC POWER FOR DRIVING TOOLS.—By Reginald A. Fessenden. Paper read before the Eng's. Soc. of West. Penn. Author explains by calculations the great saving to be obtained by electric transmission in shops, showing that if we can increase the output by 10 per cent. we can afford to pay 17½ per cent. of the entire first cost of the plant for the apparatus to do it.—"Iron Trade Rev.," Oct. 15, '96.

Railways:

POWER FROM THE TROLLEY CIRCUIT.—By H. S. Newton. Paper read before the N. Y. State Str. R'way Assoc., Sept. 8, 1896. Author presents the following questions: Is it practicable? Why do Fire Insurance Companies object? What should be done to overcome the objections? The first author answers in the affirmative and shows by a numerical example the benefit which may be derived.—"West. Elec.," Oct. 3, 1896.

ELECTRICITY ON A STEAM ROAD.—The electric equipments of the Aylmer branch of the Can. Pac. R'y is described. It is to do passenger as well as freight service and the power station also supplies lighting from a monocyclic generator.—"Can. Elec. News," Oct., '96. See also Elec. Engr.

NEW GENERATORS AT THE NASSAU POWER HOUSE.—Description of two new generating units. Generators have a capacity of 2,000 amperes at 560 volts.—Illustrated in "Elec. World," Sept. 26, '96.

ELECTRIC RAILWAY BETWEEN MECKENBUEREN AND TETTNAUG.—A trolley road near Lake Constance run on a 700-volt circuit and used for freight as well as passenger service.—"L'Ind. Elec.," Sept. 10, '96.

Telephony, Telegraphy, etc:

HOUT'S AUTOMATIC TELEPHONE SYSTEM.—Each telephone in the system is provided with a call box, and at the exchange a central appliance is so arranged that any call box in the system can instantly electrically connect the telephone to which it is attached to any other telephone in the system without interfering with ony other telephone or any other conversation.—Illustrated in "Scient. Am.," Oct. 10, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED OCT. 20, 1896.

Alarms and Signals:—

SAFETY APPARATUS FOR RAILWAY CROSSINGS. G. Gibbs, Milwaukee, Wis., 569,709. Filed Dec. 13, 1893.
Consists of an insulating section in the trolley wire of the electric line at each approach to the crossing, a feeding connection with the insulated section through a switch, by means of which current is supplied to or cut off from the section at the will of the operator.

THERMOSTATIC FIRE ALARM. H. Baer, New York, 569,851. Filed March 7, 1896.
The thermostatic bar is constantly subjected to the influence of the heat of a suitable flame and the heating effect is interrupted in case of fire when the smoke extinguishes the heating medium and closes an electric alarm circuit.

CIRCUIT CLOSER FOR BURGLAR ALARMS. C. H. Dowden, Newark, N. J., 569,861. Filed Feb. 29, 1896.
For use in connection with windows.

Conductors, Conduits and Insulators;—

WIRE CONNECTOR. H. Haug, Newark, N. J., 569,713. Filed June 10, 1896.
Consists of a metal strip bent into the shape of two adjoining and connecting channels of different size and circular in cross-section, being adapted to receive the wires to be jointed and to be twisted together.

ARMORING OR COVERING FOR ELECTRIC CABLES. H. Edmunds, London, England, 569,748. Filed Aug. 27, 1896.
Consists of wires of ordinary round form alternating with wires having recesses at their sides in which the first named wires engage.

WIRE CONNECTOR. A. Gartner, Newark, N. J., 569,752. Filed June 10, 1896.
Consists of a metal strip bent into shape of an oval tube and having its edges overlapping and adapted to slide on each other, and adapted to be twisted together with the wires.

WIRE CONNECTOR. A. Gartner, Newark, N. J., 569,753. Filed June 17, 1896.
Similar to above.

Distribution:—

SYSTEM OF DISTRIBUTING ELECTRIC POWER, ETC. W. D. Gharky, Philadelphia, Pa., 569,634. Filed July 2, 1895.
A system of wiring automatic circuit breakers.

Dynamos and Motors:—

ELECTRIC MOTOR. H. B. Collins, Fulton, N. Y., 569,746. Filed Nov. 20, 1895.
A rotary pendant head and a motor for revolving the head, the motor being provided with an armature and a field magnet magnetically co-operating to effect an upward tendency of the revolving head during the operation of the motor.

ELECTRIC LIGHTING BY WIND POWER. J. W. Gibboney, Lynn, Mass., 569,754. Filed July 23, 1896.
The combination comprises an electrical generator, a fluid motor for operating it, a closed chamber of a fixed capacity in which the motor driving fluid is stored, a variable source of power operating to increase the pressure upon the fluid and a regulator controlling the admission of the fluid to the motor.

ELECTRIC MACHINE. A. Schmid, Pittsburg, Pa., 569,802. Filed Nov. 27, 1891.
The combination with the armature of an electric motor, of a four-pole field magnet constructed in two sections, one pole and a fraction of each of two others being by each section.

BRUSH HOLDER FOR DYNAMOS. W. M. Hand, St. Louis, Mo., 569,824. Filed Jan. 27, 1896.
Comprises a block having a socket, and a carbon having a neck fitting in the socket and held therein by solder.

ELECTRIC MOTOR. W. E. Freeman, Long Island City, N. Y., 569,866. Filed June 4, 1895.
Comprises a cylindrical shell constructed of two sections with a concentric cylindrical field magnet on the interior of the head of each of the sections, the field magnet constructed in an outline eccentric to the line of the exterior of the armature.

Electro-Metallurgy:

PLATING APPARATUS. J. T. Morrow, Great Falls, Mont., 569,722. Filed April 5, 1895.
The anode consists of a perforated receptacle filled with broken metal, a conducting shoe resting upon and above the scrap metal, and the flexible conductor leading to the shoe.

Lamps and Appurtenances:—

LOCKING ELECTRIC LAMP SOCKET. W. L. Taylor, East Liverpool, O., 569,727. Filed Feb. 21, 1896.
Means for automatically locking the lamp in its socket by inserting the lamp therein and a key by which alone the lamp can be released.

ILLUMINATED SIGN. O. L. Nason, New York, 569,764. Filed Dec. 14, 1895.
Comprises a stationary outer casing, in the sides of which the letters are cut, a revoluble cylinder placed within the casing, an electric motor at one end for revolving the cylinder, and an electric incandescent light within the cylinder.

ELECTRIC ARC LAMP. H. P. Davis, Pittsburg, Pa., 569,817. Filed Jan. 14, 1895.
Feed mechanism.

ELECTRIC ARC LAMP. H. P. Davis, Pittsburg, Pa., 569,818. Filed Jan. 14, 1895.
Similar to above.

ELECTRIC ARC LAMP. J. E. Morris, Chester, Pa., 569,881. Filed April 2, 1896.
Consists of an incandescent arc light to burn as a single lamp as distinguished from those burning in series.

Miscellaneous:—

APPARATUS FOR MEASURING CANDLE-POWER OF ARC LAMPS. E. J. Houston and A. E. Kennelly, Philadelphia, Pa., 569,643. Filed May 11, 1896.
Comprises two revolving mirrors and means for varying the intensity transmitted to the photometer according to a simple harmonic law.

Miscellaneous:

ELECTRIC APPARATUS FOR REGISTERING FIGURES AT DISTANCES. M. Arndt, Aix-la-Chapelle, Germany, 569,598. Filed Aug. 5, 1895.
A mechanism for recording the oscillations or strokes of a gas balance at a distance from the instrument.

ELECTRIC BAND. J. E. Luce, Minneapolis, Minn., 569,649. Filed Oct. 11, 1895.
Therapeutic band intended to be worn in the hat.

ELECTROLYTIC PROCESS OF BLEACHING AND REFINING. B. S and L. L. Summers, Chicago, Ill., 569,680. Filed Nov. 29, 1895.
Consists in first subjecting the material to the influence of a combined hydrate and fluoride bath, passing a current of electricity through the bath, and then subjecting the fibers to the influence of a fluoride bath, and passing a current of electricity through it.

ELECTRIC GAS LIGHTING BURNER. W. E. Cram, Boston, Mass., 569,785. Filed Jan. 29, 1896.
Comprises a movable electrode connected with the gas cock and arranged to co-operate with a fixed electrode adjacent to the tip of the burner.

ELECTRICALLY WELDED PIPE JOINT. A. H. and I. C. Matatall, Harrison, N. J., 569,836. Filed Aug. 26, 1895.
Consists in interiorly reaming out both sections of the pipe, until the inward bevel extends to the periphery of the pipe, subjecting the reamed out extremities to end-to-end pressure and, at the same time, to an electrical current.

LOCK WITH ELECTRIC SAFETY ATTACHMENT. A. J. Moulart, Paris, France, 569,882. Filed June 6, 1895.
Embodies two conducting half-sleeves arranged out of contact with each other, a split keyhole sleeve surrounding them, an insulating sleeve between the keyhole sleeve and the half-sleeve, and an electrically operated signaling device in circuit with the half-sleeves.

ELECTRIC MUFFLE OR HEATER. L. E. Custer, Dayton, O., 569,911. Filed May 31, 1895.
Designed for use by dentists in the manufacture of porcelain dental plates.

Railways and Appliances:—

ELECTRIC CONDUIT AND APPURTENANCES. M. Dickerson, Fort Wayne, Ind., 569,618. Filed Sept. 11, 1893.
A system of supporting yokes placed at intervals in combination with two central slot rails, two exterior track rails, and two side slot rails for railway use.

BALL-BEARING TROLLEY PULLEY. H. N. Gale, Bristol, Conn., 569,631. Filed July 14, 1896.

UNDER RUNNING TROLLEY. N. C. Bassett, Lynn, Mass., 569,738. Filed June 26, 1896.
Means to utilize the buffer spring for the purpose of assisting the lifting springs when the trolley is in its lowest position.

TROLLEY SUPPORT FOR TROLLEY CARS. O. Holz, Schenectady, N. Y., 569,756. Filed May 2, 1896.
Embodies a trolley arm with a spring supported trolley wheel.

TROLLEY SUPPORT FOR ELECTRIC RAILWAYS. S. H. Short, Cleveland, O., 569,772. Filed June 8, 1896.
Comprises a trolley pole, a series of springs connected at one end to the pole, and a second series of springs having sliding connection with the pole.

SINGLE WIRE ELECTRIC RAILWAY. J. C. Henry, Westfield, N. J., 569,827. Filed Aug. 27, 1892.
In combination with the car, an upright rotatable standard carrying a lateral trolley arm projecting beyond the side of the car and adapted to be swung from one side to the other.

TROLLEY FOR ELECTRIC RAILWAYS. H. A. Seymour, Washington, D. C., 569,889. Filed June 15, 1896.
Embodies an electromagnet device connected with the trolley wheel holder and constructed to force the trolley wheel against the conductor.

Switches, Cut-Outs, Etc:—

MULTIPLE FUSE CUT-OUT. G. T. Voorhees, Boston, Mass., 569,692. Filed Feb. 26, 1894.

FUSE FOR ELECTRIC CIRCUIT. C. F. Scott, Pittsburg, Pa., 569,803. Filed Dec. 3, 1895.
Comprises a strip of metal having a comparatively high degree of conductivity and reduced in size at a point intermediate its ends and a body of metal having a low melting point reinforcing the reduced portion.

SOCKET AND SWITCH FOR INCANDESCENT LAMPS, 569,931. Filed Oct. 15, 1895.
Details of construction.

AUTOMATIC CIRCUIT BREAKER AND CLOSER. C. C. Drake, Trenton, N. J., 569,960. Filed July 10, 1896.
Comprises a magnet and its armature, a swinging arm engaged with the armature, a normally wound motor having a dent in the path of the arm for releasing it and a device operated upon movement of the motor for restoring the arm.

Telephones:—

TELEPHONY. J. T. Williams, Brooklyn, N. Y., 569,807. Filed March 25, 1895.
Means to eliminate the necessity of the magneto-generating apparatus used for calling purposes.

TELEPHONE TRANSMITTER. H. C. Alexander, Bonham, Tex., 569,908. Filed Jan. 6, 1895.
Consists of a diaphragm, a spring supported carbon cell, furnished with a flange faced with soft material, and a filling of granulated electrode placed in the carbon cell.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED OCTOBER 27, 1896.

Alarms and Signals:—

ELECTRIC SIGNAL FOR STREET CAR CROSSINGS. C. A. Parrish, Jackson, Mich., 570,046. Filed Jan. 23, 1896.
Means to operate three signal circuits, all supplied with electric energy from the same source, and with the use of only one set of magnets controlling circuit makers.

SIGNAL APPARATUS. J. G. Schreuder, Edgewood Park, Pa., 570,062. Filed May 21, 1896.
A fluid pressure cylinder and piston for shifting the fulcrum of a lever connected to the signal and its operating means.

SAFETY APPARATUS FOR RAILWAY CROSSINGS. G. Gibbs, Milwaukee, Wis., 570,089. Filed Dec. 6, 1895.
Means to deprive the signal man of the control of the signals

and switches after he has once placd them to allow a train on one road to pass until it has cleared the crossing.

FIRE AND BURGLAR ALARM. B. J. Lowman, Bridgeport, Ala., 570,258. Filed Dec. 27, 1894.

Apparatus which may be applied to push buttons; having automatic means for pushing the button in case its tension wire is slackened by fire or the breaking into of a building.

Batteries, Primary:—

GALVANIC BATTERY. R. W. Gordon, New York, 570,013. Filed Oct. 14, 1895.

The combination of a jar, a permeable negative element suspended therein and adapted to contain a depolarizing agent, a positive element and insulating supports for said positive element secured to the walls of the negative element and projecting therefrom and interposed between and supporting the positive element.

Batteries, Secondary:—

END ELECTRODE FOR ELECTRIC POWER STORAGE BATTERIES. J. Langelaan, Cologne, Germany, 570,028. Filed Dec. 10, 1895.

An end plate having openings therein, and the plates intermediate the end section having unbroken surfaces.

MACHINES FOR MAKING GRIDS FOR SECONDARY BATTERY PLATES. Albert F. Madden, Newark, N. J., 570,224. Filed Jan. 11, 1896.

Comprises a blank holder with cutters on each side, means for reciprocating one of the parts in respect to the other, devices for rotating the cutters and mechanism for feeding the sets of cutters toward each other.

Conductors, Conduits and Insulators:—

INSULATOR. C. B. Martin and E. M. Hewlett, Schenectady, N. Y., 570,034. Filed Aug. 5, 1896.

Especially adapted to "third rail" use.

SECTION INSULATOR. L. McCarthy, Boston, Mass., 570,140. Filed Nov. 19, 1894.

Comprises side bars and end pieces to which the side bars are attached, the end pieces having means for securing the ends of section wires.

ART OF LINING METAL TUBES WITH FIBROUS MATERIAL. E. T. Greenfield, New York, 570,165. Filed March 2, 1896.

One or more forming dies for giving to a strip of fibrous material a tubular form; means for heating the forming die in combination with means for drawing the strip always in the same direction.

INSULATING JOINT FOR METAL OR ARMORED CONDUIT TUBES. E. T. Greenfield, New York, N. Y., 570,166. Filed April 6, 1896.

Comprises a collar which is interiorly screw threaded at its opposite ends and provided with an interior thimble of insulating material.

METALLIC JUNCTION BOX AND MEANS FOR UNITING METAL CONDUIT TUBES THERETO. E. T. Greenfield, New York, 570,167. Filed April 6, 1896.

Embodies an integral screw threaded neck, in combination with a tube adapted to fit snugly within the neck and a cone-shaped ring for gripping the tube and neck firmly together.

UNDERGROUND CONDUIT. E. T. Greenfield, New York, 570,168. Filed May 11, 1896.

Comprises a pair of conduit tubes having their ends located in close proximity to each other, in combination with an expansible insulating connecting tube provided with means for uniting the opposite ends to conduit tubes.

CONDUIT TUBE. E. T. Greenfield, New York, 570,169. Filed May 13, 1896.

Consists of a metal armor and an insulating lining, liquefiable under abnormal temperatures, in combination with an interior lining of a metal which will not fuse for such temperatures as will fuse or liquefy either lead or the insulating lining.

INSULATING JOINT FOR CONDUIT TUBES. E. T. Greenfield, New York, 570,170. Filed July 25, 1896.

Consists of two cup-shaped collars secured to the abutting ends of the conduit tubes, cup-shaped collars being provided with openings for admitting molten or liquid insulating material into the annular chamber which surrounds the ends of the adjoining tubes.

ART OF MAKING INTERIOR CONDUITS. E. Lavens, Brooklyn, N. Y., 570,256. Filed March 16, 1896.

Consists in inserting a tubular lining formed of soft, pliable and resilient insulating material within a protective armor, and then effecting close union of the armor and insulating lining by reducing the diameter of the external tube.

Distribution:—

SYSTEM OF DISTRIBUTION FOR ALTERNATING CURRENTS. C. S. Bradley, Avon, N. Y., 570,118. Filed April 3, 1895.

Does away with the necessity of maintaining a balance in polyphase systems.

Dynamos and Motors:—

ELECTRIC MOTOR. S. G. Brinkman, New York, 570,424. Filed June 27, 1895.

The armature is provided with a surrounding soft iron jacket.

Electro-Metallurgy:—

APPARATUS FOR PRODUCING WIRE BARS BY ELECTRO-DEPOSITION. J. B. Forsyth and C. R. Fletcher, Boston, Mass., 570,125. Filed June 27, 1892.

Employs a cathode composed of a cylinder, with a surface of conducting material and a strip of non-conducting material laid in a spiral groove, formed in the surface of the cylinder and extending out beyond the surface.

APPARATUS FOR ELECTROLYTIC DEPOSITION. W. De C. May, Niagara Falls, N. Y., 570,133. Filed Sept. 26, 1894.

Comprises a series of receptacles arranged vertically above one another, the bottom of each receptacle extending down into the immediately subjacent one, each of said receptacles being adapted to discharge its overflow into the next of the series.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. G. C. Pyle, Indianapolis, Ind., 570,053. Filed Jan. 27, 1896.

Comprises a gravity-fed upper electrode, a lower electrode, telescoping springs to support the electrode and feed it upward and a solenoid to regulate the arc.

ELECTRIC LIGHT FIXTURE. G. A. Schmidt, Brooklyn, N. Y., 570,411. Filed Dec. 10, 1895.

A canopy for electric light fixtures, comprising a stationary cup-shaped part of larger diameter than the stem of the fixture, and a shell adjustable longitudinally on the stationary part.

Measurement:—

WATT METER. G. Hummel, Munich, Germany, 570,019. Filed Jan. 30, 1895.

A form of electric motor intended especially for the driving of wattmeters.

Miscellaneous:—

VALVE CONTROLLING DEVICE. C. E. Ongley, New York, 570,-045. Filed Oct. 30, 1893.

Comprises a motor to operate valves, consisting of a cylinder having operative valves, and a piston rod and electromagnets in circuit having the armature secured to the valve stems.

ELECTRIC HEATER. E. P. Wetmore and C. E. Roehl, St. Joseph, Mo., 570,077. Filed May 1, 1895.

Comprises a converter having a hollow secondary conductor provided with a valve for feeding a liquid or gas into the conductor, and a circuit closer for opening and closing upon itself that portion of the secondary conductor which passes through the converter.

ELECTRICAL APPARATUS. J. F. Kelly, Pittsfield, Mass., 570,310. Filed June 23, 1896.

Employs iron having a high percentage of silicon for converter plates.

ELECTRIC ELEVATOR. F. B. Perkins, Boston, Mass., 570,410. Filed Sept. 7, 1895.

Automatic safety device.

Railways and Appliances:

TROLLEY FOR ELECTRIC RAILWAYS. W. M. Whiting, East Orange, N. J., 570,078. Filed May 6, 1895.

A trolley wheel mounted on a spring controlled pivoted arm.

ELECTRIC CAR MOTOR. C. S. Bradley, Avon, N. Y., 570,119. Filed March 30, 1896.

A car truck of an electric motor mounted upon a sleeve surrounding the axle, said sleeve being supported by the car wheels upon tangentially arranged springs.

ELECTRIC RAILWAY. A. Norman, Toronto, Canada, 570,328. Filed June 22, 1895.

The track is employed as a conduit for the main conductor.

TRACK CLEANER OR CURRENT COLLECTOR. William H. Roberts, Jr., Cumberland, Md., 570,339. Filed Jan. 27, 1896.

Comprises a brush mounted on a hollow casing inclosing a spring adapted to permit the vertical movement of the casing.

Regulation:—

ELECTRIC MOTOR REGULATION. W. A. Anthony, Newark, N. J., 569,989. Filed July 29, 1896.

Claim 2. In combination, a multipolar motor, having an odd number of pairs of poles, and means for varying the action of the coils which belong to diametrically opposite field magnet poles.

RHEOSTAT. A. C. Dinkey, Munhall, Pa., 570,009. Filed March 20, 1895.

Switches, Cut-Outs, Etc.:

ELECTRIC SWITCH. S. A. Stewart, Waltham, Mass., 570,068. Filed March 12, 1896.

Electromagnets are employed to break circuit when energized by an abnormal current.

SNAP SWITCH. A. B. Herrick, Jersey City, N. J., 570,172. Filed July 12, 1895.

Comprises a snap-blade having an engaging device on its rear edge, a spring connecting the free ends of the levers, and means carried by one of the levers to engage the lug when the main blade is thrown.

CIRCUIT BREAKER. A. J. Wurts, Pittsburg, Pa., 570,212. Filed Aug 31, 1895.

Adapted for use on electric cars.

ELECTRICALLY ACTUATED SWITCH MECHANISM. W. S. Browne, Brooklyn, N. Y., 570,373. Filed Dec. 5, 1895.

Adapted for use on electric railways.

AUTOMATIC LIGHTNING ARRESTER. G. P. Johnson, Gloversville, N. Y., 570,406. Filed Jan. 9, 1896.

Electromagnets are employed to break circuit when energized by an abnormal current.

CIRCUIT BREAKER. A. J. Wurts, Pittsburg, Pa., 570,415. Filed Aug. 31, 1895.

Adapted to be operated only after a suitable predetermined interval of time.

CIRCUIT INTERRUPTING DEVICE. A. J. Wurts, Pittsburg, Pa., 570,416. Filed Aug. 31, 1895.

Designed especially for multiphase circuits.

AUTOMATIC CIRCUIT BREAKER. A. J. Wurts, Pittsburg, Pa., 570,417. Filed Jan. 10, 1896.

Means to automatically open all the branches of a multiphase circuit whenever the current in any one of the branches exceeds a certain predetermined limit.

SWITCH FOR ELECTRIC CIRCUITS. A. J. Wurts, Pittsburg, Pa., 570,418. Filed May 8, 1896.

Comprises main contacts, auxiliary contacts in shunt thereto, and a single operating handle, the movable contacts having a limited movement independent of each other, and the shunt contacts having a retarding connection with a stationary part of the switch.

CIRCUIT BREAKER. A. J. Wurts, Pittsburg, Pa., 570,419. Filed May 29, 1896.

Adapted for use in high potential circuits.

Telegraphs:—

TELAUTOGRAPH. G. S. Tiffany, Highland Park, 570,072. Filed Jan. 6, 1896.

Means for operating two separate electromagnetic mechanisms over one line wire.

TELAUTOGRAPH. G. S. Tiffany, Highland Park, Ill., 570,112. Filed June 7, 1895.

Reversing mechanism for telautograph receiving instruments.

Telephones:—

ADJUSTABLE TELEPHONE TRANSMITTER. A. Gartner, Newark, N. J., 570,204. Filed Feb. 15, 1896.

A telescopic support for a telephone transmitter.

THE CORNMAN COMPANY, dealers in electrical apparatus, write us: "We value your paper very highly for the information which it contains as to new electric light plants, etc., and we enclose three dollars herewith for one year's subscription.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE MITCHELL TEMPERED COPPER CO.

The Mitchell Tempered Copper Company, of Corry, Pa., commenced operations June 1 last in producing and manufacturing light and heavy copper castings, employing only the Calumet Hecla ingot copper. The castings are free from blow holes and sound washings, are of even temper, and in the case of commutator bars are gauged to the thousandth part of an inch. The company have a motto: "Purity, Solidity and Durability," which typifies the character of their output.

The company is well backed financially and intends giving to the trade the best copper products which can be procured for tensile strength, conductivity and durability. Capt. Dan Mitchell, formerly of the Mitchell-Brandt Company, of Erie, is the superintendent. He has had wide experience in the casting and tempering of copper. The secretary and treasurer is J. G. Ruhl, an old time railroad man with a large acquaintance throughout the State.

PATTERSON, GOTTFRIED AND HUNTER.

A visit to the large establishment of Messrs. Patterson, Gottfried & Hunter, Limited, 146 Centre street, New York, would certainly be profitable from a business standpoint to buyers connected with electric light stations, power houses, isolated plants, factories, steam plants, etc. The prospective large buyer is usually taken in hand by the genial head of the firm, Mr. Gottfried. As a house carrying a general line of machinery metals, hardware, tools, and supplies, this firm is probably the largest of its kind in America. Enumerating a few specialties of interest to electrical and other buyers, we find: aluminum and phosphor-bronze, brass and copper wire, taps and dies, blowers and forges, ash cans and fire pails, shafting and belting, iron pulleys and hangers, Shaw's patent compression flange couplings, wire rope, wire cloth, brush copper, insulating fibre, Brown & Sharpe's fine tools, gear wheels, wire and cut nails, files and twist drills, bolts, self-hardening tool steel, etc., etc. Messrs. Patterson, Gottfried & Hunter, Limited, will take pleasure mailing an exhaustive catalogue of their goods on application.

CLIMAX GAS ENGINE CO.

The ideas as to the practicability of dynamos run in connection with gas engines vary largely, owing to the fact that there are quite a number of engines on the market which supposedly come up to the requirement, but after a fair test turn out to fall short of the mark. Among the exceptions however, are the gas engines manufactured by the Climax Engine Company, 31 Fulton street, New York, of which a descriptive article can be found in the issue of The Electrical Engineer of September 16. At a full load this firm guarantee a voltage fluctuation not exceeding two volts, and gas consumption not exceeding 50 cubic feet per kilowatt hour, equal to from sixteen to twenty-five full powered 16 candle-power lamps, according to wattage of lamp used. For generators for electric elevators and electric light dynamos, especially the latter, they guarantee a light that is practically steady, which certainly is an important factor to the purchaser. The Climax Gas Engine Company exhibit at their place of business their engine with ammeter, voltmeter and gas meter in full view, thus enabling the intending purchaser to make a thorough test before buying. This firm will take pleasure also in mailing a catalogue on application.

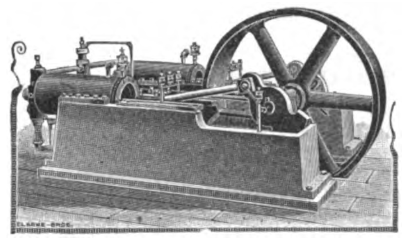
A "ROYAL" PLANT FOR JASPER, IND.

The Jasper, Ind., Electric Light Company, which was given a franchise recently, is putting in a 1,000 light dynamo built by the Royal Electric Company, with 5 miles of circuit. There will be an Erie engine of 125 horse-power, and a 100 horse-power Brownell boiler. The station is of brick and iron. Mr. Frank Joseph is president, and Mr. John L. Butz, secretary and treasurer. The plant is to be running before Christmas.

BRILL CARS IN BROOKLYN.

There have recently been placed on the De Kalb avenue line in Brooklyn, ten new cars built by the J. G. Brill Company, which are models in point of perfection both as to design and finish. They are twenty-five feet long, mounted on double trucks and are of such unusual width as to afford comfortable standing room for a number of persons sufficient to crowd to the extreme, a car of ordinary width. Double automatic sliding doors are employed, the clearance being so great as to make ingress or egress very easy. The lighting is accomplished by groups of incandescent lamps placed in the ceiling, and single lamps are ranged at intervals along the sides for the convenience of those desiring to read. These are provided with bell-shaped porcelain shades on brass fixtures and present a very ornamental appearance.

THE MILLER GAS ENGINE.



THERE has been installed and is now in successful operation in Chicago, a 50 horse-power double cylinder Miller gas engine, which is attracting a great deal of attention. This engine, shown in the accompanying engraving, is running an electric light plant and furnishes as steady light as can be obtained from central stations, and this result is accomplished without the intervention of expensive and cumbersome shafting and fly wheels to regulate the motion; and besides this is being done with the very moderate speed of 175 revolutions per minute.

The "Miller" gas engine does not operate on the "hit and miss" principle, but takes an impulse each revolution. It has a pneumatic governor with variable speed attachment and is exceedingly simple in construction. The machinery which operates the admission and exhaust valves and the igniters, is all in plain view of the operator, and contains very few parts.

The engine has cross heads for relieving the pistons and cylinders of undue wear. Gas bags, so objectionable to the insurance companies, are dispensed with. Although there are several of these engines in use in mills and factories, this is the first one installed for purely electrical purposes, and it is to be followed by another of same size, and a 37½ horse-power at once.

Electrical engineers who have seen this plant in operation express the belief that the "Miller" is a complete success and will have considerable influence on electric lighting, in isolated plants, in Chicago. The engine was sold and erected by J. M. Hayes, General Western Agent, 1119 Monadnock Block, Chicago.

E. H. KELLOGG & CO.'S ANTI-CORROSIVE AND ANTI-FRICTION LUBRICATING OILS.

There are two standard brands of oils, the Anti-Corrosive cylinder oil and the Anti-Friction machinery oil, which for years have been regarded in the electric and other fields throughout the world, as among the best in the market. These oils as well as the best grades of other lubricants are manufactured by the old and well known firm of E. H. Kellogg & Company, which established itself as far back as 1858, when the oil industry here was in its infancy. From the start their goods proved of such high merit as to cause a steady and increasing demand, so that now Messrs. E. H. Kellogg & Company claim they have more electric and water companies, etc., on their books than any other oil concern in the United States. The consumer will be astonished at the extremely small quantity of Anti-Corrosive cylinder oil required to give the most cleanly, cooling perfection of lubrication; allowing ease and regularity of motion, thus saving in power, fuel, wear and tear of machinery, and above all not losing sight of the fact that scarcely one-third of the quantity of oil is required, a large saving in expense. The same superiority of merit throughout prevails with the Anti-Friction machinery oil, which will run anything outside of a steam cylinder either high or low speed, from a jeweler's lathe to 100-ton planer. Messrs. Kellogg & Company also claim that it will compare almost three to one with lard or sperm oil. Buyers connected with electric light plants, electric light stations, railway power houses, etc., where a superior oil is of prime importance, especially for high speed engines and dynamos, will find it worth while to try these oils and lubricants, samples of which Messrs. E. H. Kellogg & Company will take pleasure in sending on application to their office and warehouse, 243 and 244 South street, New York. To facilitate their foreign business, their branch offices are established in London, Liverpool, Bremen, Hamburg, Bombay and Calcutta. Among the large number of consumers of their oils and lubricants may be men-

tioned: North German Lloyd Steamship Company, Bremen, Germany, for which they supply all oils and lubricants; Edison Electric Light Company, Columbus, O.; Ogdensburgh Electric Light and Power Company, Ogdensburgh, N. Y.; Terre Haute Electric Light and Power Company, Terre Haute, Ind.; Galveston City Railway Company, Galveston, Tex.; Ottawa Electric Light Company, Ottawa, Can.; Torrington Electric Light Company, Torrington, Conn.; Light, Heat and Power Company, New Albany, Ind.; New Orleans & Western Railway Company, New Orleans, La.; Springfield Light and Power Company, Springfield, O.; and many others.

SAMPLES AND DATA IN REGARD TO MICA MATERIALS.

A very interesting addition to existing data on insulating materials has recently been issued by the Mica Insulator Company, of New York, Chicago and London, in the form of a collection of samples of the various insulating materials which they manufacture, together with the results of actual tests on these various materials attached to each sample. Results are given on tests of the necessary voltage to break down a given thickness of each of these materials, and also on the specific insulation resistance. The figures given are the average of a large number of tests under various conditions, and are taken from the experiments of Herrick & Burke.

The Mica Insulator Compnay has realized that in order to fulfill all the requirements of insulation, it is necessary to manufacture various qualities and kinds of materials, as there is no one universal quality of insulation. Their samples cover a number of grades of "Micanite" insulation, consisting of a number of combinations of mica, mica and cloth, and mica and paper, of various degrees of flexibility. Also a number of grades of "Empire" insulation, which consists mainly of specially prepared and insulated cloth and paper. From a technical standpoint, the collection is very interesting, because it not only shows the various kinds of materials manufactured, but also is indicative of the advances that have been made in the preparation and manufacture of insulating materials, from a mechanical and an electrical standpoint, and the high degree of perfection that has been reached in this line of elctrical industry.

BARRUS & MONROE.

George H. Barrus and William S. Monroe announce that they have opened an office in The Rookery, Chicago, as mechanical and electrical engineers and experts. Mr. Barrus has been engaged in business as expert and consulting steam engineer for the past twenty years, with headquarters in Boston. The character of his work is widely known not only in the East, but also in the West. Mr. Monroe has been in business as mechanical and electrical engineer for the past two years, having an office in The Rookery, Chicago. He was formerly in the employ of Burnham & Root, architects, as mechanical engineer, and later he served as one of the principal assistant engineers at the World's Columbian Exposition. They are prepared to lay out and superintend the construction of steam and power plants, electric lighting and railway systems, steam heating plants, and ventilating systems, making the necessary preliminary estimates and preparing the plans and specifications required. They also inspect and test steam and electric plants for determining questions of fulfillment of contract and those of efficiency and economy of operation; besides undertaking to examine and test old plants with a view to reorganize the same and making them economical. They give personal attention to tests of boilers, engines and electric apparatus, to investigations of steam appliances, etc. They make estimates and valuations, also serve as expert witnesses in legal actions, and as referees. Their headquarters are in The Rookery.

NEW YORK NOTES.

NEW YORK CITY.—The Greater New York Signal Company has been formed by J. Fleischhauer, A. Lexow, C. K. Lexow and others, with a capital stock of $5,000.

THE BELL ELECTRIC COMPANY, of New York City, has been formed to deal in electrical appliances, by C. E. Potter, F. M. Bell, and J. R. Kein, with a capital stock of $150,000.

NEW YORK CITY.—The Greater New York Electric Light and Power Company has been formed by J. Fleischhauer, A. Lexow, C. K. Lexow, and others, with a capital stock of $50,000.

THE WALDEN ELECTRICAL SUPPLY COMPANY, Walden, N. Y., have recently bought out the electrical supply business of the Fowler Hardware Company and are in the market for electrical supplies of every description.

MR. THOMAS J. FAY, for a number of years the New York representative and late general manager of the C & C Electric Company, has severed his connection with that company and is about to join the ranks of consulting electrical engineers.

MR. HENRY MILLER, JR., late of the New York Carbon Works, has associated himself with the Phœnix Carbon Manufacturing Company, of St. Louis, and is making his headquarters at 136 Liberty street, New York, and will be pleased to welcome all his old friends at his new quarters.

MR. ELMER P. MORRIS, 36 Dey street, has accepted the agency for the East of the Automatic Circuit Breaker Company's goods, of Newaygo, Mich. He will carry a full line of samples of their various devices, and will be pleased to show them in operation to all interested who will call at his office.

THE ERICSSON TELEPHONE COMPANY, Home Life Insurance Building, New York, N. Y., are manufacturing a line of domestic instruments for long and short distance desk, warehouse, hotel and inter-communicating systems, etc. They will use the imported Ericsson Swedish coal grain microphone on all of their domestic instruments.

E. T. CALDWELL, Thirty-one East Seventeenth street, city, makes a specialty of designing only the most artistic and unique of combination electric and gas fixtures. Among the many places installed with Mr. Caldwell's work can be mentioned the Waldorf, Hotel Imperial, Hoffman House, new part of Savoy, Boston Public Library and many others. Mr. Caldwell manufactures a great many exclusive designs of combination gas and electric fixtures to special order.

NEW ENGLAND NOTES.

THE SESSIONS FOUNDRY COMPANY, of Bristol, Conn., have recently favored their friends with a handsome picture of their works. It is an excellent lithograph, well mounted, in an oak frame 24 x 40 inches, and makes a most desirable ornament to any office. This company is one of the largest in New England engaged in this field and supplies castings for all classes of work. They have paid particular attention to electrical business, and experience in this department enables them to meet all requirements of their patrons and guarantee the quality of their product.

JOHN M. FOX & COMPANY, electricians, Portland, Me., report construction business as very good. They have finished a 200 light electric plant at Hodsdon Bros'. shoe factory, Yarmouth, also Dr. Baker's six houses at Woodfords. Their contract for these called for electric light wiring throughout, wiring each house for electric bells and also the furnishing and putting in of the electric fixtures and shades, some 140 in number. Besides these, they have wired four other houses at Woodfords; the I. O. O. F. block, Saco; Mr. Walsh's residence at Lewiston; Mr. Chas. Payson's new block, Portland; put in additional lights on steamer Portland for the Portland Steam Packet Company, and several others, and have filled besides numerous contracts for bells, fixtures, etc.

WESTERN NOTES.

THE ELECTRIC APPLIANCE COMPANY are meeting with large success as the General Western Agents for the Taunton Copper Manufacturing Compnay, and are now carrying a large and complete stock of their celebrated bare copper wire. They state that their customers seem to appreciate the advantage of having a complete stock of bare copper wire carried in Chicago from which they can draw in large or small quantities, as their needs demand.

MR. ALEX. CHURCHWARD, electric engineer of the Excelsior Electric Company, was a recent visitor to Chicago, where he superintended the installation of some new plants in which their handsome machines are to be used. Notwithstanding the constant cry of hard times during the past few months, Mr. R. J. Randolph, the energetic Western representative of this well known company, has closed up some nice new business for them.

THE STANLEY-CARLSON TELEPHONE MANUFACTURING COMPANY have removed from the Springer Building, 172 South Clinton street, Chicago, to more commodious quarters in the Dunn Building on Jackson and Clinton streets.

THE METROPOLITAN ROAD in Chicago, on October 9, "Chicago Day," when two great political parades took place, carried no fewer than 90,000 people in the 24 hours. The electric trains ran with the utmost regularity. Mr. W. E. Baker, the general manager, says that during the past six months, there has not been a single delay of a train or a single defect in the electrical apparatus.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. NOVEMBER 11, 1896. No. 445.

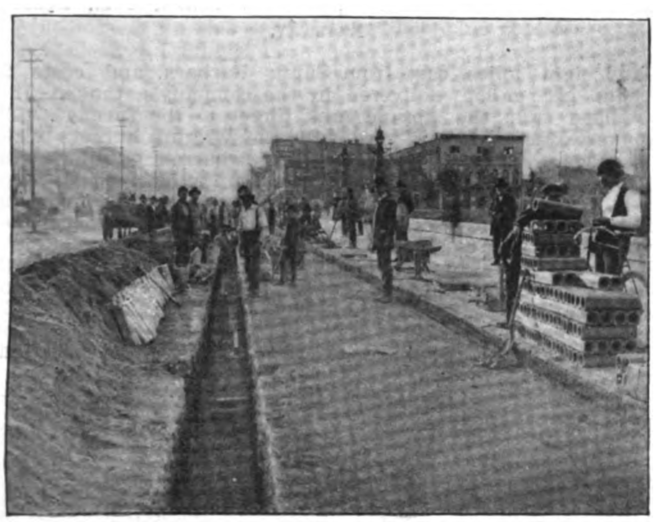
TELEPHONY AND TELEGRAPHY.

UNDERGROUND TELEPHONE WIRES IN INDIANAPOLIS.

SINCE the beginning of Fall the work of placing the telephone wires in Indianapolis underground has gone on apace and when completed the city will be comparatively rree from overhead wires, at least in the densely populated and business portion, including the vicinity of the State House.

The system in Indianapolis, when complete, will require nearly seven miles of trench in the streets and alleys. Over 260,000 feet of pipe will be laid and 95 manholes will intercept the conduit at various points.

The conduit used is the single duct vitrified clay pipe, manufactured by the H. B. Camp Company, at Greentown, Ohio. The pipe is carefully selected and cleaned out before being laid and after the conduit is finished and before the pavement is restored, the ducts are cleaned by a device consisting of, first, a length of iron pipe to gather up mortar and debris, then a spiral wire brush, following which is a steel flue scraper and another spiral iron brush. The sections vary from 200 to 600 feet in length. No difficulty has been found in previous work at Columbus and Toledo in drawing cable into a duct 600 feet long and over.

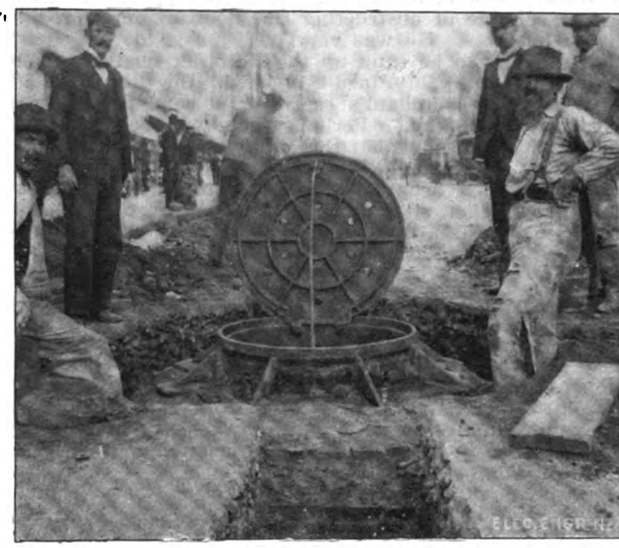


TELEPHONE CONDUIT IN FRONT OF INDIANA STATE CAPITOL.

Of course, where such long sections are used, it is necessary to have the pipe laid very carefully. All the grade lines are laid by transit and level and the pipe is put in with side lines from point to point, thus insuring an absolutely straight conduit from one manhole to the next. In places where straight runs cannot be obtained, owing to obstructions found in the ditch, extra manholes are placed so that if difficulty is found in drawing in cable, it will be but for a short length.

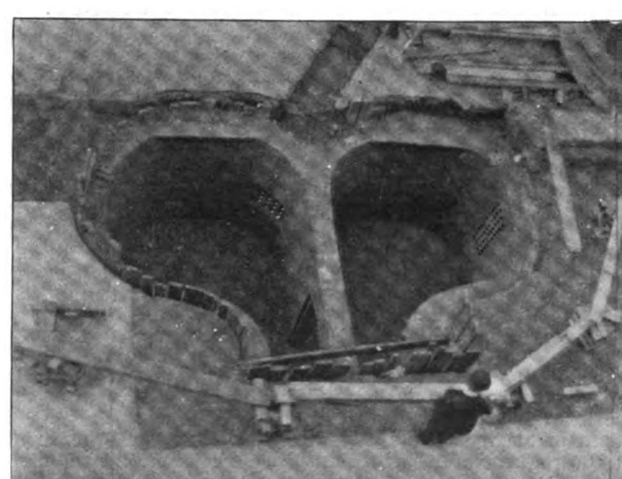
The manholes are of the well known barrel-shaped pattern, being similar to a longitudinal section of an ordinary barrel. They are large, varying in size from 5 to 8½ feet long. The office manhole is larger than this and is shown in one of the accompanying views.

The manhole cover used is of special design and is shown in the accompanying engraving. When the cover is raised, the end of the iron rod locks in place and holds the cover in an upright position to form a protection to the opening, thus saving the use of a tent or iron railing to be carried to the manhole in which work is done. This device of having the cover form the protection to the opening, has been used in several other systems, notably those in San Francisco and other Pacific coast points, with good success. As the manhole walls are built, bolts are set in at intervals near the top and to hold the cables on the walls, pieces of oak are imbedded in the floor of the manhole at one end and secured to these bolts at the other, iron cable supporters being then screwed to these wooden uprights at the proper distances.



MANHOLE WITH COVER RAISED.

It is intended to use 120-pair cable in the system, which can now be manufactured within a diameter of 2¼ inches. The distribution will be from poles set in the intercepting alleys, to which the cables will be run by laterals, these laterals being constructed of the vitrified clay pipe, but to carry the cable up the pole an iron pipe bend will be used, one end of which is bell-mouthed to fit against the clay pipe and the other end on the pole screw-threaded for jointure



BIRD'S EYE VIEW OF EXCHANGE MANHOLE.

with the iron pipe passing up the pole. Where necessary from the underground terminal poles, multiple aerial cable distribution will be used, especially in the business districts where it will be necessary to distribute from the cable at many points. This system is now successfully in operation in Toledo and to some extent in Columbus, Ohio.

Work was started on the last day of August and all the main runs are now practically finished. The first of November saw the main conduits completed and the majority of the laterals constructed. The shorter laterals are left until next spring.

The work is in charge of Mr. E. M. Jackson, Superintendent of Construction for the Central Union Telephone Company, who has a long experience in this class of work.

TRIAL BY TELEPHONE.

Neither Bell nor Edison ever dreamed of an application of the telephone that was made by a Montclair (N. J.) merchant last week. The merchant was cited to appear in court to answer a charge of obstructing the sidewalk in front of his place of business. He was very, very busy, too busy in fact to go to court, so he rang up the Recorder on the telephone and pleaded guilty. "Fined $10," said the Recorder. "All right," was the merchant's reply. "I'll send up the money right away. Good-by." Perhaps there will be more of this trial by telephone now that the Montclair man has blazed the way. Why not examine witnesses over the telephone, too? And let jurymen hear cases in the same manner. A busy merchant can then sit in his office with a telephone hood on his head and hear a divorce case, while he dictates letters to his typewriter or talks politics with his customers.

NEW YORK FRANCHISE WANTED FOR DRAWBAUGH TELEPHONE.

The Drawbaugh Telephone Company has filed its application for franchise with the New York Board of Electrical Control. J. R. Bartlett, president of the Drawbaugh company, is absolutely confident that a franchise will be granted, and that the new telephone and telegraph company will soon be in operation in New York City.

ORIGIN OF THE BEAUTIFUL WORD "TELEGRAM."

According to a San Francisco paper, it was E. Peshine Smith, the grandfather of Mrs. Rudyard Kipling, who originated the word "telegram." It would be injustice to the memory of the late Amos F. Learned, a Boston boy, remarks the "Boston Herald," to allow his claim to go unchallenged. Amos was the agent of the Boston Associated Press in New York, and it was in the hurry of sending dispatches during the war of the rebellion that the inspiration came to him to shorten the conventional "telegraphic dispatch," to "telegram." His claim was made on all occasions, and is not known to have ever been disputed before.

BELL TELEPHONE INSTRUMENT OUTPUT.

The statement of the Bell Telephone Company's instrument output for the month ended October 20 shows:

	1896.	1895.
Gross output	14,766	14,969
Returns	7,252	6,350
Net	7,514	8,664
Ten months:—		
Gross output	163,161	143,192
Returned	75,799	67,815
Net	87,362	75,377
Total number of instruments outstanding October 20, 1896	762,338	657,883

FREE MEDICAL TELEPHONES IN CHICAGO.

H. B. Stone, president of the Chicago Telephone Company, has issued orders authorizing physicians to use the automatic or pay telephones for communication with the health department free of charge. This privilege was brought about at the request of Health Commissioner Kerr and will be welcomed by physicians generally. The latter frequently discover in their professional rounds cases where the public health is endangered or persons whose condition is such that charity should be immediately extended them. Communication with the health department by telephone is simple and efficient, but the regular fee of 10 cents was an obstacle. The telephone company has, therefore, instructed its operators to allow doctors to communicate with the health department without the usual charge.

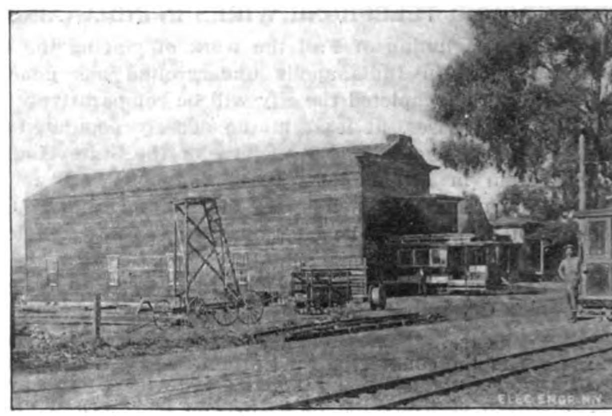
ELECTRIC TRANSPORTATION.

THE SANTA BARBARA ELECTRIC RAILROAD.

WITH OIL FUEL.

THAT quiet old mission town, Santa Barbara, California, succeeded in putting in operation an electric railway on October 1 last, after several years of agitation on the subject.

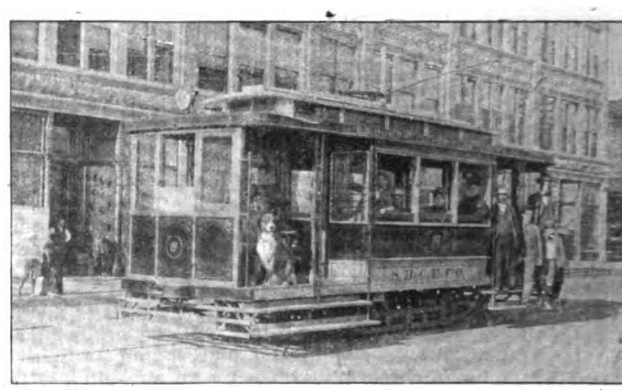
The new road extends diagonally from east to west across the city. The power plant and car house shown in our illustration are located near the freight depot of the Southern Pacific Railroad on a lot 225 x 230 feet with a private track connecting with the steam road for the purpose of handling fuel, etc. Crude oil is used for fuel, which is obtained from Sommer-



POWER HOUSE AND CAR BARNS, SANTA BARBARA, CAL., ELECTRIC RAILWAY.

land eight miles east from Santa Barbara, and costs 2¼ cents per gallon delivered in the company's tanks. It is pumped from the storage tank direct to the furnace. The compression system is used with the Wilgurs burners which atomize it thoroughly, using about 2 barrels of oil per car, per day, of 18 hours. A flowing well on the lot provides ample water for the boilers. The power plant is equipped with the Oil City Boiler Works boilers, Ideal engines and General Electric Company's 6-pole generators.

The cars, one of which we illustrate, were built by the California Car Company, of San Francisco, and are of the combination style originated in San Francisco and are peculiar to the Pacific coast; they have 28-foot bodies, 8 feet 4 inches wide and seat 32 people, with roomy aisles. The closed part



FIRST ELECTRIC CAR, SANTA BARBARA, CAL.

is seated with Hale & Kilburn's reversible cross seats and has double sliding doors with 3 feet 2 inches opening. On each platform are two longitudinal seats facing out with space ample for motorman between the backs. Each platform seats eight people. These seats are much sought after by visitors, smokers and young people.

The company have recently purchased all the equipment, properties and franchises of the Citizens Street Railway Company and the Santa Barbara Street Railway Company and now control all the street railway interests in the city with 50 year franchises for two desirable suburban lines.

Our illustration shows the first car run over the road by Miss Hattie K. Miller, daughter of the president of the road, and also the final trip of the old motive power which was retired on a pension.

The officers of the road are: C. W. D. Miller, president; A. Hope-Doeg, vice-president; H. S. Luster, secretary and treasurer.

LAST TRIP OF MULES OVER THE SANTA BARBARA ROAD.

CLEVELAND AND CHAGRIN FALLS ELECTRIC RAILROAD.

THE electric railway connecting Cleveland with Chagrin Falls, now rapidly nearing completion, combines several novel features worthy of extended description. The length of the road is about eighteen miles, and runs from Cleveland to Chagrin Falls by way of Warrensville. The cars start from the Cleveland Public Square and run over the old Woodland avenue and Kinsman street line, now a part of the Cleveland Street Railway system, to the terminus, which is four miles distant. It there starts on its own tracks and runs for a distance of eight miles on the pike road, where it enters its own private right of way which covers a distance of five miles.

The road throughout is built in accordance with the standard steam railway practice. The Cleveland and Chagrin Falls Company have a binding arrangement with the Cleveland City Railway Company by which after the cars enter Cleveland upon the local Electric Railway Company's line the C. & C. F. conductor and motorman leave the car and transfer it and its passengers to the local railway company's employés; these men to take the car to the Public Square, collecting from each passenger a five cent fare, and also on such traffic as they are able to pick up on the way. On the return trip from the Public Square they pick up passengers, either local or interurban and collect from each a five cent fare as before, and deliver the car to the C. & C. F. employés at the end of the line with its load of passengers. It is further arranged between these two companies that the C. & C. F. Company get a certain percentage of the fare receipts. After the car reaches the inter-urban part of the system, the registers will be taken down and the fare transaction made according to the ordinary steam railway custom.

There is to be but one power house which will be located nearly midway between the two terminals of the line. This power house is to be built of brick and of suitable dimensions for car house and repair shop.

The electrical equipment for the power house consists of two Walker dynamos, 150 kilowatt capacity each, direct connected to Russell & Company Corliss engines, and run at a speed of 150 r. p. m. These dynamos are of the latest and most approved design, multipolar type; the magnet yoke is of cast iron; the pole pieces are of soft iron laminated, and cast into the yoke. They have pole shoes of cast steel, which serve also to keep the magnet spools in position. The armatures are of the iron clad type; the plates are punched in segments from soft, well annealed iron, and are secured by dovetailed projections fitted into corresponding slots milled in the rim of the spider. The laminated core is divided into a number of sections separated by one-half inch air spaces, allowing ample circulation of air. The armature winding consists of flat copper ribbon formed into proper shape previous to assembling, and is entirely without joints except at the commutator leads. The coils are very thoroughly insulated and are held in place by phosphor bronze bands. The commutator is so constructed that the bars are held in place by a sectional clamp, so designed as to draw the bars firmly down onto the flat cylindrical surface of the spider. The current density in the carbon brushes at full load is a little less than 35 amperes per square inch.

The dynamos will be fitted with the latest and best design of brush holder. The engine adjustment, by means of a threaded spindle and hand wheel is used, with which the brushes need but a single adjustment in the correct position and they will run sparklessly at any load up to a heavy overload.

The switchboard will be of black enameled slate and highly polished. It will consist of two main panels and one feeder panel. On the two main panels will be one station voltmeter, 750 volts; two ammeters of 400 amperes capacity each; two automatic circuit breakers, 300 amperes each; two lightning arresters; two polished three-pole switches; two rheostats, etc. On the feeder panel there will be two ammeters, two circuit breakers, two lightning arresters and two single pole polished switches.

The car equipment will consist of two motors each, of the Walker well known No. 10 type, 50 horse-power each. These motors will embrace the latest inventions in spring suspension, the principal features of which have been fully described before in our columns.

These motors are made for severe service and high speed. The frame is made of soft steel, the armature of the softest annealed iron, and the insulation used is of mica and fuller board covered with waterproof paint and tested to 5,000 volts pressure in the shops. Another important feature of this motor is the arrangement of the bearings, which are entirely outside of the motor casing, and which, therefore, excludes the possibility of oil and grease getting inside the motor.

The new Walker trolley will be used on these cars, a description of which was given in The Electrical Engineer of July 8 and July 22.. The Walker controller of the latest and most improved design will be used, there being one controller for each car.

The power plant consists of two Russell four-valve automatic engines of 225 horse-power capacity each, built by Russell & Company, Massillon, Ohio. The cylinders are 17 inches diameter by 24 inches stroke, and the fly wheels are 92 inches diameter by 18 inches face, mounted on shafts 12 inches in diameter. The shafts run in self-oiling bearings. The engines run at 160 revolutions per minute, and they are built on lines suggested by a long and intimate experience with the requirements of electric railway duty. An iron base extends under engine and dynamo making a self-contained outfit for each unit.

The boilers are two in number of the tubular pattern, each 72 inches diameter and holding 70 4-inch tubes by 18 feet long, and built to carry a working steam pressure of 125 pounds. The arrangement of the power station is such that an increase can be made subsequently without disturbing the original installation.

There is to be one single acting feed pump, and one duplex feed pump, both of the Stillwell & Bierce pattern. There is also one 500 horse-power Stillwell & Bierce heater. The water for the boilers will be supplied from a pond made and owned by this company, and located in close proximity to the power house. The stack will be sixty inches in diameter, and eighty feet high.

The rolling stock will consist of five cars, the motors are Walker, two of which will be placed on each car, of a capacity of 50 horse-power each, and mounted one on each truck. Each car will be furnished with double trucks manufactured by the McGuire Company, of Chicago.

The cars are being built by the Pullman Palace Car Company, are vestibuled in the same manner as the general interurban car, and will be furnished with air brakes. The inside finishing of the cars will be in oak. The seats will be finished in rattan, and each car will be provided with the general accessories of the ordinary steam railway equipment.

The track construction consists of Carnegie 60-pound T-rails, except in the town of Chagrin Falls, where the girder rail will be used. The trolley wire will be No. 00 suspended on brackets, manufactured by the Ohio Brass Company.

It is expected that this road will be in operation within sixty days, when the company will begin to run its cars regularly every forty-five minutes.

TROLLEY TRAIN TIME TABLE. The Akron, Bedford and Cleveland Railroad, trolley system, issues a regular time table for its service, enumerating some 60 trains daily, and showing eleven stops between termini. The running time is about 2½ hours per trip. The cars connect with street car lines, by transfers, at each end.

THE MODERN POWER HOUSE.—III.

BY R. MC CULLOCH.

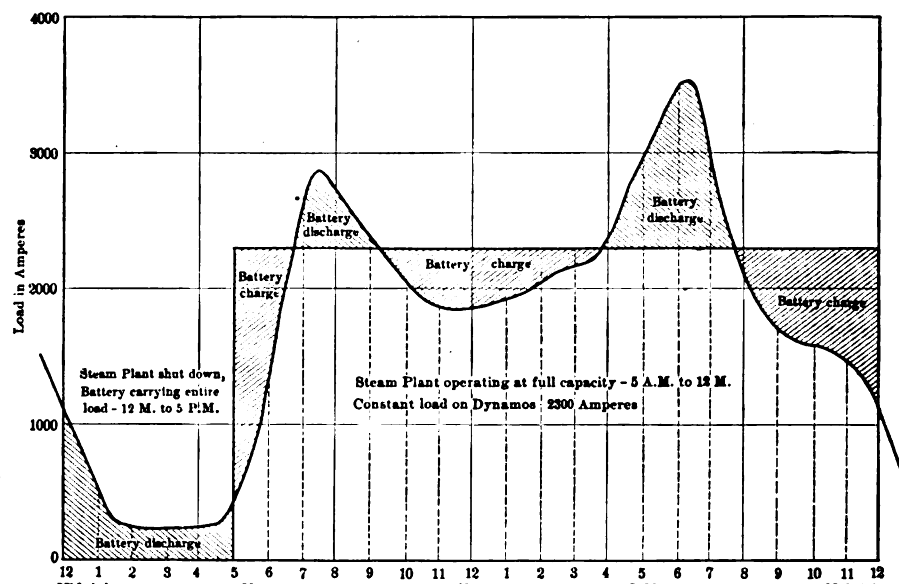
(Concluded.)

If readings be taken of the total output of the power house at stated intervals and then plotted, a load curve will be obtained similar to that shown in Fig. 1. A study of this will show a very small load through the night from 1:30 a. m. to 5:30 a. m., a sudden rise at this point to a maximum about 7:00 a. m., a lower load through the middle of the day, followed by another peak between 6:00 p. m. and 7:00 p. m., after which the load again suddenly drops. In order to accommodate the machinery to the varying load, the number of dynamos in circuit must constantly be changed, and even then it is almost impossible to suit the power at all times to the load, the dynamos running much of the time either overloaded or underloaded, which, of course, means a sacrifice of economy. In addition to the variation of load shown by the curve, there is a momentary fluctuation, due to the starting and stopping of cars, the violence of which decreases with the number of cars in service. It is proposed to remedy this variation and operate the dynamos under a steady load by means of a storage battery plant connected in parallel with the line, charged from the dynamos during the period of light load, and discharged into the line on the heavy call for power. The operation of the plant under these conditions is indicated in Fig. 1. Installations of this sort have been placed in several of the large electric light plants where they are operating with marked success, and there is no reason why they should not meet with the same degree of success in electric railway plants. By means of this auxiliary plant, the proper number of dynamos are run throughout the entire day at their full capacity and hence at their highest efficiency, the battery taking care of all eccentricities in the load, charging when the load is less than the capacity of the dynamos, and discharging when the load exceeds this. The steam plant may be shut down entirely during part of the night, leaving the battery to operate the road, and in case of a breakdown, the battery may be used to take care of the entire load for a short time. The battery is discharged through a booster dynamo, which is so designed that the compounding of the dynamos and the battery are the same. This arrangement is entirely automatic, so that no hand regulation is required. The efficiency of a battery operating under conditions of this kind will be guaranteed by the manufacturers to be greater than seventy-five per cent. and a maintenance of sixty per cent. on the first cost of the battery will be guaranteed. The great drawback to this system of operation is the large first cost of the battery which is about $100 per horse-power capacity figured on a two-hour discharge rate. A storage battery plant may also be used to increase the capacity of an existing power house and thus save the necessity of adding more machinery. There is another use to which a storage battery plant may be put which will, perhaps, appeal more strongly to the street railroad man. This is to install it as a substation to maintain the voltage at the end of long feeders, which are subject to fluctuating loads. In this case the batteries are charged from the distant power house and discharged into the trolley wire. The feeders from the power house to the storage batteries are figured only for the average load instead of the maximum load as would be necessary in case the line is fed directly from the power house. The economy in this installation depends very largely upon the difference in cost between the feeders in the two cases. Besides the question of economy, however, the substation will give the better service as the voltage will not fall and rise with the fluctuations of the load.

A number of power houses operating long lines are now equipped either with boosters or high voltage dynamos. Long lines usually have a booster constantly in circuit. This machine is automatic in its action and raises the voltage with every increase in the load. Some power houses operate a high voltage dynamo for use on sections which are subject to excessive loads. The feeder boards in this case are equipped with an extra bus bar, so that any section may be thrown on the high voltage machine.

While each individual engineer has his own ideas concerning power house construction, and while each road building a power house may purchase different apparatus, there is one general design which has been followed in many of the plants usually installed. It has been adopted by so many different engineers and in so many different places that it might almost be called the Modern Power House. The general features of this design are shown in Fig. 2. The engine room and boiler room are divided by a brick wall and under different roofs; both are brick buildings, covered with an iron truss roof; the boiler room is set on the grade of the street and the engine room ten or twelve feet above this grade, the space below the engine room being utilized for the piping and condensers; the engine and boilers are set at right angles to the wall between them, with the engines next to the boiler room, so that the piping is made as short as possible and the condensation lessened; the switchboard and feeder board are set on the opposite side of the room from the boiler room, so that the length of the dynamo cables is equalized as much as possible. The general features of this design may be summed up as follows: it is compact to save real estate and buildings and to minimize the number of employés and the superintendence. Large units are used for the sake of economy and to save the number of working parts. The building is as far as possible fireproof.

The electric part of the problem has been solved, temporarily at least, but the adoption of the multipolar, direct coupled dynamo. The large, slow speed engine has followed as a necessary consequence and the general direction of improvement in power house construction seems to be toward the use of devices to prevent the waste of heat and to minimise the labor required.

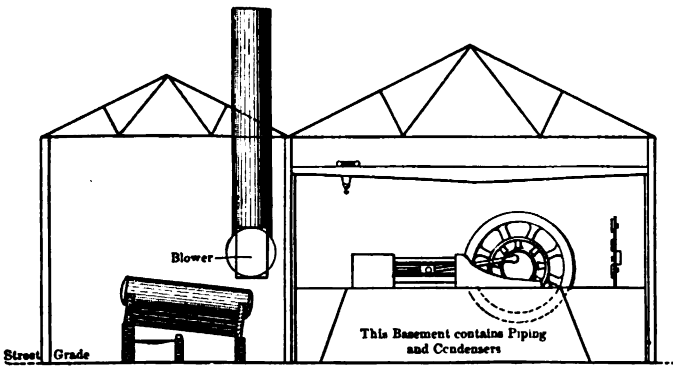


STORAGE BATTERY OPERATING IN PARALLEL WITH STREET RAILWAY PLANT.

Battery capacity—700 H.P. at two hour discharge rate.

FIG. 1.

There can be no more appropriate place to quote the proverb that cleanliness is next to godliness. An engine and dynamo room should be kept scrupulously clean. This is especially true in regard to the electrical devices, as a very small amount of grease and dirt in the wrong place will cause serious damage. Beyond the mere æsthetic consideration that cleanliness improves the looks of things, there is also the fact that a thorough cleaning amounts to a rigid inspection, and small leaks and defects are often discovered in this way which might otherwise pass unnoticed until they had become serious matters. It is to be regretted that this advice is not more generally followed, as there is more lost through dirty and greasy electrical devices, badly set valves, leaky steam joints, poor firing

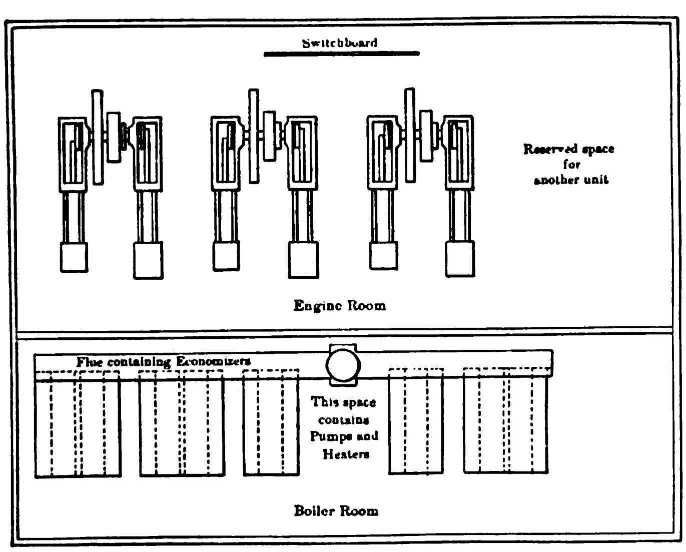


SECTIONAL ELEVATION.

FIG. 2.

and careless supervision than ever will be gained through the use of compound, condensing engines.

As a means of comparing different kinds of machinery, figures as to cost of operation have been collected from some of the large modern power houses, and their comparison reinforces what has just been stated, that less depends upon the refinements of the machinery, than upon the condition in which the apparatus is kept and upon the supervision to which it is subjected. Among those having the lowest cost of operation was a power house, equipped with direct coupled generators, but operating single cylinder, non-condensing engines, burning soft coal and using hand firing, while among those having the highest cost of operation are several power houses supplied with compound condensing engines, and burning anthracite coal. The lowest results are about three-quarters



GROUND PLAN

FIG. 3.

of a cent per kilowatt hour, some records running slightly below this, while the results from some of the large stations are as high as 1¼ cent per kilowatt hour. These figures include the cost of coal, water, supplies, repairs and all labor, but do not include anything for taxes, insurance, interest or depreciation. The cost of operation depends largely upon the cost of coal and upon the relation of the average load to the total capacity of the power house, the higher this ratio, the less being the cost of operation.

The modern electric railway power house, although it has been developed entirely within the past ten years represents the thought and the experience of many men. It has been developed carefully, detail by detail, until it is now a work both of reliability and efficiency. No one man and no one company can claim the credit for this achievement, but no class of men hold a stronger claim to recognition than the managers and owners of street railroad properties, who have ever been ready to encourage with their patronage each improvement, who have freely distributed the information gained by their experience, and who even in the most radical departures have ever acted with the courage of their convictions.

THE SELECTION AND MANAGEMENT OF EMPLOYEES.[1]

BY W. F. KELLY.

"It is a good divine that follows his own instructions; I can easier teach twenty what were good to be done than be one of twenty to follow mine own teaching."

An intelligent consideration of a man as an operative presupposes a knowledge of the conditions and environments under which the operative exists. What these conditions are, or seem to be, depends largely on the point of view. The public view it from one point, the employés from another, the manager from a third, and the stockholders or owners from still a fourth.

To the public mind a street railway is the visible, tangible property with which they are in daily contact, and the intangible, shadowy something which they call the management. The physical character of the property they judge of by observation. The management, they judge by the character of the employés with whom they are in daily contact. In a large system perhaps not one in 20,000 have ever seen the president. The mild-mannered, long-suffering manager, known and beloved by his friends and neighbors for his many kindly virtues, is too frequently in the public mind the embodiment of all that is selfish, cold-blooded and rapacious. If the common talk of the everyday world is to be believed, he delights in irritating and insulting the public, in the oppression and abuse of his employés, and is always endeavoring to rob the people or the city of their rights.

How does such an impression become current? Perhaps through the publication of his official acts and partly through the men employed on your cars. The employés reflect the character of the management, and whether we wish or not, the public consider the car employés with whom they are in daily contact, as representing their policy and attitude toward the public. We touch the public and have our measure taken largely through the men who man and operate your cars.

The pernicious idea that anybody can run a street car has in the past resulted in the employment of an army of careless, coarse and incompetent men, who through their ignorance, carelessness and incivility, have done more to bring street railways into public disfavor than all the official acts of its management and directory. The manufacturer selects his salesman not on account of his knowledge of his wares, but more largely on account of his ability to meet and treat courteously prospective customers. The management has time to discuss a fare register, sandbox or a truck, but has not an hour to give to the choosing of its public representatives. The selection of the human machine, which is far more important, more difficult to understand, more difficult to operate, causes the most trouble and expense, and fails most frequently, is too often entrusted to a man already burdened with many details.

The manager thinks it essential to have a competent, well paid man to purchase necessary supplies. If cars, motors or power station machinery are to be purchased, he gives it careful, personal attention, and calls to his aid skilled experts, in order that there be no error in so important a matter.

Every employé of a street railway should be considered as an agent with possibilities of harm to his employer. It is not enough that he is intelligent, sober and industrious. He should be of good judgment and sound thinking, and neither communicative, socialistic or anarchistic in his views; not discontented and at cross purposes with the whole social order, but of cheerful disposition and content to make the best of life as he finds it.

The physical and intellectual qualities of the applicant should both receive careful consideration; well-bred, sound, vigorous men, with a fair common school education, can be readily secured, and the wideawake management should be satisfied with nothing less. In order to exclude many undesirable applicants, a high standard of physical qualifications should be established and adhered to rigidly. Certain previous occupa-

[1] Read before the Am. St. Ry. Assoc., St. Louis, Oct. 19-23, 1896. —Abstract.

tions are considered as disqualifying. Policemen, firemen, steam railroad employés, political appointees are as a class undesirable. There may be individual exceptions, but they are rare.

Friends or relatives of the directory or other company officials, relatives or political friends of city officials, brothers or near relatives of present employés are frequently inefficient and troublesome. They are a dead weight on the neck of the active manager and no matter how excellent the reason, every dismissal involves an explanation, and frequently ill-feeling on the part of those who have been favored by having their friends appointed. Fitness should be the sole standard for securing a position. The manager should have no favorite or relatives on his force, and should be wholly untrammeled by his directory or superior officers. Either he is large enough to discharge the duties of his office without suggestion as to details, or else the property needs a new manager.

In large systems the duties of general manager are so numerous that he thinks it impossible to devote his time to the employment and discharge of conductors and motormen. Then by all means relieve him of many of these. Plenty of competent men can be found to purchase materials, jolly the council, place insurance, adjust damage claims, etc., but few men have the clear judgment and broad-mindedness to select the best class of men for their service and to deal fairly, firmly and kindly with their faults and failures.

No class of public service is more exacting than that of the street car employé. In no other business do the public get so much for their money and grumble so much because they don't get more. In no other business is the employé so much the personal representative of his employer as in this. What do we expect and require of him? That he always be prompt in reporting for duty; always quick and accurate in the various details of his business; honest, sober, intelligent, trustworthy, clean, courteous, smiling, patient, good-natured, never weary, always ready to help everybody, always obedient to several dozen or hundred rules; in fact, a model of all the virtues for $2 a day. Desiring all these, there are some managers who require yet more. I have in mind one prominent city road, in which nearly all the employés are of one religious belief, and others find it difficult to secure employment. Another, in which all employés are opposed to this belief; and yet another in which they are almost wholly of foreign birth or parentage. In the first two cases, this condition arises largely from the personal prejudice of the manager, and in the other through a mistaken notion of economy. It is fair to assume that neither of these managers are of that broad gauge type which places high character and efficient service above political or religious creed.

Granting that there has been careful and intelligent selection it is equally important that there be wise and considerate management.

The electric motor and the cable have ushered in the new era of city surface transportation. New blood and new capital entered the field, but many of the old customs and old employés remained. The change from animal to mechanical traction has been swift and startling. In many places the horse car is but a memory and the mule driver is an extinct species. Track, cars, and power station up to date, but the method and management of the men who operate the cars is that of the past decade.

It is conceded that a different type of man is necessary, and on various systems, there has been a noticeable change since the horse car days. True to natural law, the fittest have survived and a superior class of men now operate the cars. There has not been on the part of managers in all cases so marked an improvement in the modification and amelioration of various harsh practices. It is urged that the more intelligent, superior type of man is deserving of better treatment than the mule whacker of ten or twenty years ago. Frequent and severe punishment for petty offenses should be abolished and a code of rules established worthy of the men and the business they represent. The almost universal practice in punishing minor offenses is to "lay off" the employé from one to ten days, without pay, which is, in effect, a fine of from two to twenty dollars. The man is soured, his family suffers from the loss of earnings, and if the man happens to be a conductor it is not surprising if he tries to get even by nipping fares. The practice is still adhered to by many railway companies, and the offenses which the punishment is supposed to correct still continue. Such a practice would not be countenanced in a manufactory, a store or in commercial affairs; why should it be on street railways? If the man is valuable enough to be retained in service, why should his family suffer the loss of his wages? If the man were permitted to continue at his work and one-half the amount he would lose by laying off were assessed as a cash fine, the practice would be condemned in unmeasured terms, both by the press and an indignant public. If employés are not amenable to reprimand administered in a proper way, then they have not your welfare at heart, and should be dispensed with altogether. An entry, together with date, should be kept of all occurrences connected with every employé. It should show his absence from duty, whether from sickness or other causes, his various little lapses from duty, disobedience or neglect of orders, etc. This record should be frequently examined by the manager, and when it is evident that the man is making no improvement, replace him at once without waiting for "something to happen."

All foremen and sub-foremen should be impressed with the idea that all men under their charge should be treated in a gentlemanly manner and with the utmost fairness; that there shall be no favoritism in recommending men for promotion or in shielding them from punishment. Much depends on the integrity and good judgment of the division foreman. It is, therefore, highly essential that there be no mistake in selecting men for these positions. If they are not active, loyal and interested in their work, discipline will be lax and unsatisfactory service the result.

Employés should not be censured for light or trivial causes or on ex-parte testimony. Reprimand should be kind but pointed and manly, and never in public or in the presence of his fellows. Deal fairly and justly with every man and teach the man to feel that his case will receive careful, unbiased consideration, and that for similar offenses the same and certain punishment will follow in all cases.

Drinking on duty, drunkenness, frequenting saloons or gambling rooms, or association with loose women are all inimical to good service, and merit dismissal.

Revise your rule book and eliminate all useless and harsh rules and insist on a strict observance of the remainder. Study it and see if many old customs should not be abolished and new ones inaugurated. Put yourself in the employé's place and see how many of them you think are necessary in order to secure efficient service.

A number of large railway companies have in recent years furnished comfortable and attractive waiting rooms for their men, with reading room, lavatory, etc. This is neither charity nor generosity. It is a plain business proposition that the company will obtain better and more satisfactory service if the men have cosy and attractive quarters about the car houses. The manager too frequently thinks that when he has done all this, his men have no cause for complaint and that they are ungrateful and unappreciative. Let him look beneath the surface and discover the cause of the irritation. He will probably discover that somebody or something is not receiving fair play. That there is some discrimination in promotion, punishment, hours of labor, etc. The grievance may be only imaginary, but until it is considered and adjusted it creates grumbling and discontent as surely as a real one. To obtain the best service there must be a feeling that the manager has a personal interest in the welfare and success of his men. Prizes for good conduct and satisfactory service, beneficial organizations, reading and recreation rooms are all helpful and in the right direction; but courteous and manly treatment, and a kind word now and then smooth away the irritations of an exacting service more than all else. The man must feel that you respect his manhood, integrity and fidelity; that aside from his service as an employé you have a human interest in his success as a man. He has a right to feel that years of right living and faithful service entitle him to your confidence and that his good character should shield him from evil report.

Improved conditions, shorter hours of labor and better wages have all contributed to make street railway service more desirable and attractive to a high class of labor. Formerly it was considered that street railway men were necessarily a shifting, thriftless class, whose term of service was of brief duration. Street railway managers seemed to think it a part of the daily programme to discharge somebody or employ somebody—anybody—in his place. Men looked upon it as a makeshift job—a chance to pick up a few dollars while waiting for something better to turn up. The result was a miscellaneous aggregation of men with no higher interest in the welfare of their employer beyond receiving their wages. Happily this condition is fast passing away, and the best street railway systems to-day are those which have given most care and attention to the selection and treatment of their men.

We may never reach that ideal condition where every man is capable, honest and trustworthy. It is none the less worth striving for, and the manager who most nearly approaches it has within his grasp the highest elements of success. With the whole body of employés loyal, faithful, intelligent and devoted to their duty, gross earnings would be increased and operating expenses diminished, personal injury claims be reduced to a minimum, secret service agents no longer necessary, the occupation of the labor agitator gone, the kicker silenced and that peace of mind of which the general manager now only dreams, will become a reality.

THE KENSINGTON SPRINKLING CAR.

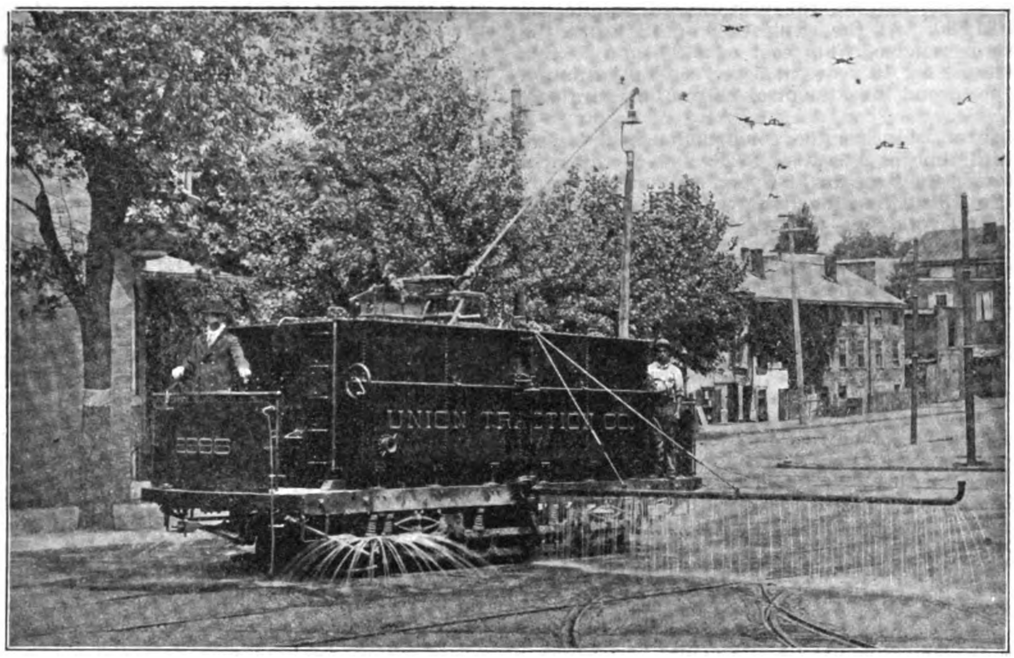
THE sprinkling car shown in the accompanying engraving is built by the Kensington Engine Works, Limited., Philadelphia, Pa., and combines in its design and construction a number of new and attractive features. It is provided with a tank 16 feet long, having a capacity of 3,000 gallons; enough, it has been demonstrated, to effectually sprinkle about three miles of road.

The tank is made of plate steel and provided with six baffle plates extending from side to side, making seven compartments, communicating with each other by triangular openings in the corners of the plates, preventing swash of the water in case of violent stopping of the car. Manholes and openings for filling the tank conveniently and quickly are at the top, and there are two hose connections arranged at the ends on opposite sides for filling from plugs when that is desired. Ladders from front and rear platform give easy access to the top of the tank and float tell-tales at each end indicate the height of water carried at all times.

To sprinkle over the track and within a short distance upon each side, perforated pipes are provided at both ends of the car; these curve outward and return to the side of the truck. To sprinkle the street a considerable distance on both sides of the track, two swinging arms are provided with perforated pipes carried on cranes that swing in a half circle, with a radius of about 18 feet, making a total width of road sprinkled of over 45 feet. These arms are worked from either platform, by hand wheels actuating a worm engaging wheel on the post of the crane. In case of necessity, these arms can be swung against the car in ten seconds, and are entirely out of the way.

The water valves are of a quick-opening design and are placed beneath the car. They are worked by levers on the car platform, so that control of the entire apparatus can be had from both platforms. The Kensington sprinkling car is mounted upon the standard trucks and driven by the usual motors and electrical attachments.

The Union Traction Company has equipped its entire lines in Philadelphia with these cars, using eleven for the work.



THE KENSINGTON SPRINKLING CAR.

MODERN OVERHEAD CONSTRUCTION.[1]—I.

BY BENJAMIN WILLARD.

IN the equipment of electrical street railways the item of overhead construction is a very important one, and one susceptible of many ideas. There are many different methods and kinds of materials used on overhead work, all of which would go to make up practical and modern construction, but as a matter of fact there are hardly any two installations which are near alike. The reason for such a variety of construction is naturally the result of engineers' ideas, conditions and opinions relative to the merits of different manufactured parts. It is hardly possible to standardize an methods and appliances in such a way as to meet the general approval of different engineers, as the requirements vary with local conditions, and what may be found practical in one locality may be found faulty in another.

My ideas relative to what is necessary for practical modern construction will undoubtedly differ in many respects from the opinions of others, and in some instances may be found not practical, but experience has proven to me many important features to be observed in modern construction, and I can only submit what in my opinion and during my experience I have found to be substantially practical.

Trolley line construction can be erected in various ways and still conform to good practice, one difference being in the kind and cost of poles to be erected. There are various requirements governing the selection and kind of poles to be used which determine an important factor in the first cost. Municipal requirements may compel you to erect steel or wood poles, or you may be allowed to make your own selection. In the first instance the price is fixed and you have only one thing to do; in the second instance you have opportunities which are left for your own discretion. The steel pole presents a neat and attractive appearance, also takes up a small amount of space, which are the chief points in its favor. The insulating qualities are not as good as with the wood pole, and although I am not prepared to say positively as to its lasting qualities, I have made some observations on deterioration of wrought iron columns that have been in the ground for several years, and estimating that this deterioration would take effect in the same proportion on steel poles, I am convinced that in a moist climate a limit on the practical life of such poles would not be over thirty years. While I am not strictly an advocate of wood poles, I am of the belief that from a practical and financial standpoint, wood poles should be used in many instances.

Through the business sections of cities steel poles are in some respects better, as they are not affected by being wilfully or accidentally mutilated. In suburban or resident districts the wood poles when properly dimensioned answer every purpose, and appear fully as well as the steel poles. A heart pine or cedar pole will, if properly selected and kept painted, last in some climates twenty years. This is a known fact from observation on poles that are now in sound condition after having been erected for that length of time.

Suppose we select New Orleans as a suitable location to build a road and base our estimates on cost of material there. The cost of steel poles would be greater than in many northern cities owing to freight rates and distance from the manufacturers of such poles. Wood poles can be furnished for less in New Orleans owing to their near production, so that I think

[1] Read before the American St. R'way Assoc.—Abstract.

an estimate covering cost at that point would be a fitting proposition elsewhere.

Steel poles for one mile of span wire construction, 104 poles at $15 each, would cost $1,560, and assuming their life to be 30 years, the interest on your investment for 30 years at 5 per cent. per annum would be $2,340 or a total first cost and interest of $3,900. The setting of steel poles necessitates the use of concrete which is an expense to be figured over the cost of wood pole setting, so we must figure at least the cost of such material and labor which would be $4.50 per pole, or $468 per mile, figured with interest for 30 years at 5 per cent. per annum, would be $1,170, or a total for interest and first cost of material and labor of $5,070, which is to be considered against the cost of one mile of wood pole construction covering the same period.

Assuming the life of wood heart pine poles to be 12 years (instead of 20 years) I will base a comparative propositon on that basis, taking the interest on each investment and carry it through to the expiration of 30 years. Wood heart pine poles for one mile of span wire construction, 104 poles to the mile at $4.50 each, would cost $468, also suitable labor and material for erecting at $2.50 per pole, $260, or a total first cost of $728; to this must be added interest for 30 years at 5 per cent. per annum, $1,092, making the first investment at the end of 30 years $1,820. At the expiration of 12 years the construction must be renewed at a cost of $728, and to this must be added interest for 10 years at 5 per cent. per annum, $655.20, making the second investment at end of 30 years cost $1,383.20.

At the expiration of 24 years the construction will be renewed for the third time at a cost of $728, and to this will be added the interest for 6 years at 5 per cent. per annum, $218.40, making the third investment at the end of 30 years cost $946.40, a grand total for wood pole construction of $4,149.60. The difference between total costs of steel and wood pole construction for a period of 30 years would be $920.40 per mile, which would be more than a liberal allowance for changing span wires and other work, but assuming it would take this amount we would stand even at the end of 30 years and still have 6 years more paid for on wood pole construction.

If steel span poles are used, I would recommend for the average span of 40 feet a pole weighing about 700 pounds, made in two parts. The lower section to be constructed of 6 inches extra heavy, and the upper section of 5 inches standard steel pipe swaged at the joint for a distance of 18 inches. Such a pole to be 28 feet long, 18 feet for the lower and 10 feet for the upper section, and provided with a cast iron and wood pole top for the attachment of the span wires. Such poles should be provided with a wood filling to fit the bottom of the lower half to prevent it from sinking, and should be set 6 feet in the ground with a rake of 10 inches from the perpendicular to allow for being straightened when under strain. The average size of hole to be dug would be 20 inches in diameter with a depth of little over 6 feet, requiring (after the pole is inserted) a mixture of about one-half cubic yard of concrete composed of one part of Portland cement, two parts of sharp sand, and four parts of broken rock. The cement should be given at least three days in order to set firmly before attaching the span wires. Whenever it is practical to allow poles to bear against the curbing this should be taken advantage of, as it affords an efficient stay to assist the pole in resisting the strain. Should it not be possible to secure use of the curb (or paving) a good sized rock having a bearing surface of about one square foot would assist very much, and keep the pressure from cracking the cement.

If wood poles are used, where it is necessary to make neat appearing and substantial construction, I would recommend for the average span of 40 feet a long leaf yellow pine pole dressed and chamfered, 30 feet long, sawed square, 11 in. x 11 in. at the base, and 7 in. x 7 in. at the point, free from sap, rot or knots, and corners evenly chamfered 1¼ in., beginning at a point 14 feet from the base, and terminating in an octagonal form and roofed evenly for a space of 3 inches.

In setting wood poles where concrete is not used (and I do not consider it necessary) a great deal depends upon the soil encountered. Whereas it is necessary to use very little prepared material for filling in some localities, it will take a quantity in others, so I will mention what would be required in a soil of medium clay and character which would probably meet the average condition. Poles should be set 6 feet in the ground with a rake of 12 in. from the perpendicular to allow for being straightened when under strain, and the hole should be dug to a vertical depth of 6 feet (or more, if necessary, to allow the pole to stand a given height above the track) in the ground, and should be about 2 feet square at the top, and not less than 18 inches at the bottom. Where it is practical to allow poles to bear against the curbing (or paving) this should be taken advantage of, and it will not be necessary to use other material near the surface as in iron pole construction, but it will be necessary to place a substantial bearing at the heel to prevent the pole from pressing through the earth; for this purpose a small quantity of coarse broken stone or brick bats will answer every purpose, and where this is not easily obtainable, and the earth is soft, a piece of plank 12 in. wide by 3 in. thick, 4 feet long sharpened and driven into the earth to a depth of about 2 feet at the back and base of the pole will give good results.

Whenever it is necessary to erect poles in the absence of substantial material at the surface, such as paving or curbing, I would recommend that the base of the pole be well rammed with broken rock for a distance of 18 inches, taking pains that the greater quantity is placed at the back where the pressure is greatest and leaving a small quantity in front where no pressure takes place. The space to within 20 inches of the top may be filled with earth taken from the hole and well rammed. To prevent the pole from yielding at the surface a breast plank of oak (or cypress) timber 3 in. x 12 in. x 6 feet should be placed and spiked in front and at right angles to the pole about 8 inches under the surface of the ground, which would make a suitable bearing surface, and resist the span wire strain. About 20 inches from the top of the hole and in front of the breast plank should be filled and well rammed with the same material that is used at the base of the pole. The necessary quantity of broken rock required would be about 2-10 of a cubic yard to the pole.

Poles of wood or steel, which may be used for holding strains at curves, should necessarily be heavier than those used for straight line construction and should also be set at greater depth in the ground. Steel poles of proper dimensions for curve construction would be made in two joints and constructed on the same principle as the straight line pole, excepting with heavier dimensions of pipe. A steel pole for curve construction should be 29 feet long, made of 6-in. and 7-in. extra heavy pipe, the larger section to be 19 feet long, and the smaller section to be 10 feet long and made to weigh 1,050 pounds. Such poles should be set 7 feet in the ground, and raked 10 inches from the perpendicular in a direction radiating from central point of curve where strain is required. The filling necessary would be the same as specified for straight line iron pole construction.

Wood poles for curve construction would be made similar to those specified heretofore for straight line construction, excepting dimensions of such poles should be 31 feet long by 14 in. x 14 in. at the butt, 9 in. x 9 in. at the top, chamfered from a point 14 feet from the base to the point terminating in an octagonal form and roofed evenly for a space of 3 inches. Such poles should be set 7 feet in the ground and raked 12 inches from the perpendicular in a direction radiating from the center of curvature where strain is required. The hole should then be entirely filled with about 7-10 of a cubic yard of broken rock and well rammed.

ROENTGEN RAYS.

ROENTGEN RAY APPARATUS.—THE CURRENT INTERRUPTER.

BY PROF. W. M. STINE.

WHEN the great Spottiswoode induction coil was constructed, very considerable difficulty was experienced in producing regularity and sharpness of the interruptions of the primary current. It seems singular that during the twenty years which have elapsed, no material progress has been made in either the invention or refinement of mechanical or magnetic breaks. Except to a few investigators, the problem has not been a pressing one. This condition is now changed, and the very widespread use of Röntgen tubes necessitates new and improved methods for interrupting the exciting current.

As introductory, a number of general considerations claim attention. For the maximum production of Röntgen rays, a spark shorter than popularly supposed seems best adapted, but this spark must be a thick one, or otherwise the secondary current must have considerable intensity. This occurs when there is the most complete resonance in the primary circuit. The condition of resonance results from the proper proportioning between the capacity of the condenser, the exciting current and the time rate of interruption of the exciting current. When the primary circuit is broken, the e. m. f. of self-induction forces a spark across the gap. If the contacts readily volatilize, the vapor formed by the arcing reduces the resistance of the air gap and delays the decay of the exciting current.

Another important consideration is the goodness of the contacts. Using low e. m. f. for exciting the primary, the resistance of a poor contact very materially cuts down the exciting current.

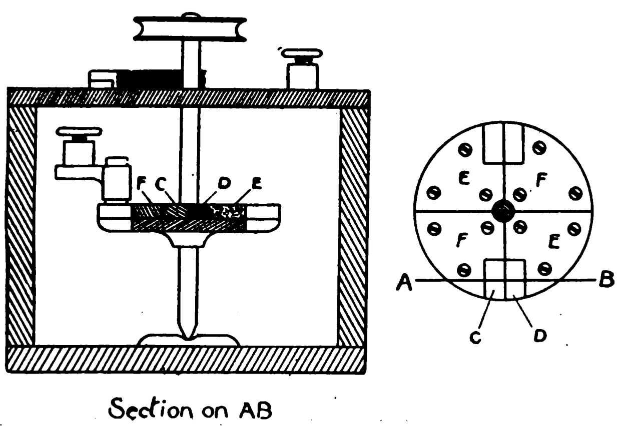
The problem presented, then, is to prevent arcing at the contacts and to insure a firm electrical contact of high conductivity.

Interrupters may be broadly divided into two classes,—mechanical and electromagnetic. We may now proceed to an examination of particular types.

Mechanical Interrupters.—(1) A form much used consists of a number of radially projecting lugs attached to a shaft rotated by a motor. The circuit is completed by a spring strap struck by the projecting teeth, both contact parts being usually of copper. Vicious arcing occurs and the tendency has been to attempt to suppress this by adding condensers across the gap. The result is that the coil is thrown out of resonance, which, added to the prolongation of the current by the arc, produces a thin spark. The spark also varies in length, due to the varying resistance of the contact by the vibrations of the spring.

(2) A modification of this type is made by filling up the gaps between the contact teeth with some non-conductor, making a smooth periphery. The vibration of the spring is prevented, but the arcing is rather increased, and a more uncertain action of the coil results. Through constant arcing the periphery soon becomes indented, and the spring contact is impaired.

(3) To this type have been added two devices for lessening the arc. One means is to direct a jet of air on the contacts



Figs. 1 and 2.—Under Water Break Wheel for X-Ray Coils.

at the instant of interruption, as is done in the Thomson-Houston arc dynamo. This is fairly successful. Another method employs an electromagnet for "blowing out" the arc. This seems even more efficient than the air jet. With both methods, however, the spark is thin, and they require nearly double the exciting e. m. f. really necessary to operate the coil. As a result, the spark length is very uncertain, and there occurs an occasional spark of extremely high voltage which is very liable to puncture the tubes.

(4) The water break, which will be noticed below.

Electromagnetic Interrupters.—(5) The mercury break is perhaps the most powerful of this class. A pin actuated by the magnetism of the core of the coil dips into a vessel of mercury. Upon its withdrwal a violent arc occurs, vaporizing the mercury. If water be placed on the mercury, the arc is quickly extinguished. With this break the coil is most powerfully excited, but the mercury is soon whipped into a thick paste or emulsion, and besides, there frequently occurs an extremely powerful spark apt to puncture the tube.

(6) The usual vibrating make-and-break. This device may be called a standard one from its almost universal application, and for ordinary work leaves little to be desired. It has several bad points, however. The tension of the spring is not readily adjustable, and, in common with all vibrating springs, being rigidly fixed at one end, it takes up harmonics and produces irregular sparks.

(7) This type consists of an iron lever actuated by the magnetism of the core. Since in the writer's experience this form has given the most uniform and powerful results of all the various mechanical and magentic devices tested, a detailed description may be of interest.

This device was made by Carpentier, of Paris, and deserves to be more generally used. The dimensions of the lever are 3 x 5-16 x 1/8 inches. It is pivoted through the edges, so as to present a flat surface to the core. Near one end is a contact screw, tipped with platinum; near the other, a hole 1/4-inch diameter is drilled, and a flat spring projects over it. The tension of the spring is readily adjustable, and the speed of the vibrator can be varied through wide limits. It has been found best to braze platinum tips cut from No. 6 wire to screw points. The large contact surface insures good action and long life, while new points may be inserted with the greatest ease. This device is now in constant use on a coil capable of yielding sparks 14 inches in length. By its use either the pear-shaped or focus tubes can be so powerfully excited as to easily penetrate all portions of the body.

For exciting old tubes in which the vacuum has become abnormally high, a mechanical interrupter is employed.

The use of water in the mercury break suggested running a mechanical interrupter under water. For several months the writer has been experimenting with this device. It has been found, in brief, to be the most efficient mechanical interrupter so far tried. It may be constructed in a variety of styles. The particular type which gave the best results was that described above (2). The contact wheel and brush were immersed in water, and the arcing was almost wholly prevented. The wear on the brush and contacts was extremely rapid, due to oxidation by the electrolytic action of the spark at the interruption of the current. Since the brush is the part more readily renewed, it was operated with a positive polarity. Various metals were tested for contacts and brushes, but copper and silver gave best results. The same device may be run in oil, but oxidation will still occur. Though it proved to be the most successful of the mechanical interrupters, yet it was abandoned on account of the destructive electrolytic action.

From this type, however, was developed a mechanical interrupter which proved quite satisfactory. A vertically mounted shaft carries a disk, shown in Figs. 1 and 2. Bearing on this is a carbon brush, soft, and containing a good deal of graphite. The essential features of the disk are the removable insulating and contact pieces. The main insulation is by two quadrants of rubber (E, E). The spark occurs at the juncture of each pair of removable strips (C D). One of each pair is of glass, the other of either brass or copper.

In operation the arc is found to be short and but little destructive, the wear falling principally on the carbon brush. When the metal contacts are too worn for use, they may be readily replaced by removing two screws in each.

Letters to the Editor.

POWER TRANSMISSION AT FAIR HAVEN, VT.

In an article in your issue of October 21, on "The Present State of Electrical Transmission," by Dr. Louis Duncan, a list is given of the plants now in operation.

I have no feeling in the matter, but think it due to our friends, the Westinghouse people, that it should be recognized that our plant is one of the successful power transmission plants of the country. It has been done in a quiet way, no stocks, bonds or scrip being issued, simply everything built for cash and as an investment. It includes a water power developed (our least noted volume 500 horse-power) of 120 feet fall, two steel tubes 500 feet each to a 100 horse-power and 150 horse-power wheels, with a small one 25 horse-power for separately driving exciters, a 150 kilowatt two-phase and 75 kilowatt single-phase, supplying power to motors 2, 4, 7 miles each, lighting two towns 4 and 11 miles distant, by arcs and incandescents, driving a 75 kilowatt two-phase motor synchronous at quarries 7 miles off with the motor so built and equipped with all instruments that it can be driven as a generator from the steam plant kept in reserve there and so protect the lighting of the two towns in case of accident at the Falls.

As I stated above, it has been done quietly, avoiding newspaper notoriety, but taking up and solving all the problems of long distance transmission, power (we started the first two-phase motor in New England for commercial purposes) light, heat and cooking.

We have no desire to have our names in the papers, only to be included in the lists when given of power plants.

CONTENTS.

THE ELECTION AND AFTER.

With an emphasis that no man can mistake, the American people have expressed their opinion in regard to the dishonest delusion that when times are hard the way out is to issue money which as bullion is not worth half the value stamped on it, so that debts may be paid in a debased currency. It would have seemed that this world of ours had been through that experience too often with failure and disaster to try it again, and had found out too often that no government stamp can ever give fictitious value to anything, but humanity is liable to crazes of this kind, and it takes a large amount of education and a high sense of public morality to fight them down. By nearly 100 votes majority in the electoral college and over 1,000,000 majority in the popular vote the brains, wealth, conscience and public spirit of the United States have defeated the proposition that this country should be a repudiator, and the verdict has at once carried with it the promise and the certainty of better days. Our financial and banking system is still in need of many reforms, but they will now be sought on the lines of common decency and normal fair dealing.

While the vote for sound money has been so overwhelming, we believe that it would have been even larger but for the profound feeling of distrust and defiance as to the organizations now grouped in popular parlance under the general head of "combines and trusts." The Bryan vote was not altogether a vote for silver, and it would have been much smaller if Mr. Bryan had only been the spokesman of the silver combine, but Mr. Bryan was able to make an appeal to the discontented and unfortunate that was all the stronger because it embraced many half truths and probably some whole truths as to the favoring of certain groups of producers or manufacturers at the public cost. There will be and there must be legislation in further check upon those who, by massing influence and wealth, propose to drive others out of business. Unrestrained competition is bad, but, if we understand the public temper, it is felt that unrestricted combination is worse.

In this respect, as in many others, the Republican party is on trial, its great victory having been achieved solely with the help of patriotic Democratic voters, and it remains to be seen how fairly it will hold the scales and adjust the burdens of taxation. Capital and the fruits of labor can best be protected by equitable laws that deprive even the visionary or the discontented among us of any grounds for assault, and enterprise will be the quicker to manifest itself when there is no fear that selfish monopolies can interpose to deprive any one of his reward or his occupation.

In the electrical field the new era opens auspiciously, and with the dawn of last Wednesday morning better times began for every branch of electrical industry. Our own pages bear witness to the renewed activity of all kinds of electrical enterprises, and there is every reason to believe that only a beginning has been made. It is for this reason that at this moment we hasten to deprecate and condemn the measures attributed to the General Electric Co. We hear of efforts made by it within the last few days to swing street railway companies into line by offering to let bygone purchases of alleged "infringing" apparatus be forgiven for one dollar, but tieing up the companies, as an offset, in regard to further purchases, except on payment of $50 for each motor equipment bought outside, and $1 per horse-power for generators. The evidence as to this move is tolerably specific, and, in fact, would be hard to conceal. If this be the continuing policy of the company, we do not hesitate to brand it as detestable.

CONVEYING THE ELECTION NEWS.

ACCOMPANYING the intense excitement over the recent election went an eager desire for early and full news as to the result. An article appearing elsewhere in our pages gives an excellent idea of the manner in which, with the aid of the latest and best electrical apparatus that could be secured, the newspapers proclaimed the news either on their novel bulletin boards to thousands or by means of flashing mid-air beams to waiting distant millions of people. Large sums of money and extraordinary ingenuity were expended, and the results were commensurate in the brilliant success achieved.

Last week we noted a good deal of the special work in this line done by the telegraph and telephone companies. Speaking from personal experience, we can pronounce the telephone experiment a great hit. The news given out telephonically was remarkably full and accurate, not presenting mere little bits of local results, but including the whole country in its scope. We sat, like many thousands of other telephone subscribers, with the telephone at our ear from 7:30 p. m. to 10:30 p. m., and in that period received and posted up for assembled friends some 250 excellent bulletins, winding up with the evidence of McKinley's election. The long distance telephone services, in all the cities, are to be heartily congratulated on their good and thorough work. Sitting at home quietly, one missed, no doubt, the hurly-burly of the big, shouting outdoor mobs of excited enthusiasts, but one got all the news and got it quickly.

The telegraph companies, as we stated last week, have had to make very heavy preparations, and the work of which we spoke was well done. The Western Union Company, from the fact of its universal ramifications, bore the brunt of the more general service from all the States, and the number of its bulletins from the various distributing points must have run into millions. For example, between 6 p. m. Tuesday and 4 a. m. Wednesday it sent out 523 bulletins over more than 500 wires, making over 260,000 bulletins from this city alone. In this city and Brooklyn it had over 400 special wire connections, as against 161 four years ago. In Chicago the number of orders for wire service reached over 250; in fact, the work done was everywhere limited only by the number of operators obtainable.

The Postal Telegraph Company reports also having done an enormous business, especially in the cities to which it has always confined its efforts more particularly. In Philadelphia it had 150 special election customers, and states that there as in Chicago "election return parties" with its service became a feature of the occasion. When to all this work is added that of the press associations, it will be seen that the peak of the load ran up to a height heretofore undreamed of, while the service was cheaper and better than ever before.

Electrical means of communication are desirable at any time, but they are best appreciated in the hours of great popular emotion and excitement, when the fate of a nation hangs on the flash of the searchlight, the click of the sounder and the vibration of the telephone diaphragm.

SILVER AND COPPER.

THERE is now a chance that silver as a metal will reach its proper level and sell for what it is actually worth. It has too long been regarded with an absurdly superstitious reverence and much too seriously treated as a "precious" metal. The simple plain facts are that at present rates of production and without the bolstering up of government credit silver is likely to go lower in price. Even then the producer has a handsome margin of profit when his cost is only 17 or 20 cents an ounce. Silver has few qualities of special merit, being heavy for its value, easy to imitate, readily attacked by acids, and tarnishing at the contact of a mere rubber band; while on a lower plane of values, iron and copper are long likely to remain preferable. It remains to be seen what effect on the price of copper the presumably smaller extraction of silver may have. As shown in our pages recently, in much of the electrolytic copper working in the West, the by-product of silver has been a handsome profit in itself, and it remains to be seen also whether the price of copper in view of the larger demand for that metal and the lesser demand for silver may not affect Montana to the benefit of the Lake Superior copper regions. It is possible, on the other hand, that cheaper silver may be more largely used in the domestic arts and decorations. If so, the value may not go off very seriously and there may still be sufficient incentive to the active working of the Western copper-silver deposits. The situation is evidently interesting, and in the meantime we note hardening prices for copper, with a decline in silver.

EDUCATIONAL.

DR. SHELDON ON ELECTRICAL MEASUREMENTS OF PRECISION.

DR. Samuel Sheldon delivered a lecture on Friday evening, November 6, before the Electrical Department of the Brooklyn Institute on "Recent Methods in Electrical Measurements of Precision." The lecture was given in the physics lecture room of the Polytechnic Institute. The following is a synopsis of what was said by the lecturer:

There has been an evolutionary advance and improvement in methods of electrical measurement which is entirely commensurate with the recent advances in general science and its commercial applications. The quantities which we are generally called upon to determine are those which enter into Ohm's law, viz., current, resistance and difference of potential. Accompanying these, determinations of length, mass, time, and temperature are often required. If the accuracy of the determination is such that an error of 1 in 1,000 is not permissible, the determination may be called a measurement of precision. Commercial measurements are seldom objected to when the errors amount to 1 or even 5 per cent. of the magnitude of the quantity measured. Commercial measurements of insulation resistance have been accepted when the inaccuracy was probably 75 per cent. Such measurements by means of a Weston voltmeter are often accepted.

In nearly all cases so-called electrical measurements are really comparisons with some standard. Measurements of resistance are very seldom made. Instead, a comparison with a wire standard is made. It will thus be seen that to determine all or any of the three above mentioned magnitudes necessitates the possession of standards of at least two of the magnitudes. A few years ago the accepted standards were of resistance and of current. To-day they are of resistance and electromotive force.

The resistance standards of a few years ago were faulty in many respects. Their absolute magnitudes were not in accordance with the system of units they were supposed to fit. Their material was German silver, platinoid or platinum silver, materials which possess fairly large and surely uncertain temperature coefficients. Added to this, they were generally constructed in such a form as to ensure an uncertainty as to the actual temperature of the wire. When made in the form of resistance boxes, the plugs, blocks, and posts, possessing an appreciable resistance, were sometimes included in the nominal circuit and sometimes not. To-day we have three materials which have practically negligible temperature coefficients, viz., manganin, constantin and a material known under the trade name of Ia Ia. In addition to this the form of modern resistance standards has been improved so that the temperature of the wire can be very accurately determined.

The old standards of current were the tangent galvanometer and the silver voltameter. A precise measurement with the former instrument required first of all a very accurate measurement of the dimensions of the instrument and a faith that they would remain constant during the whole determination. In the second place it was necessary to determine, by a tedious method, the value of the horizontal component of the earth's magnetism. The constancy of this value was never to be relied upon in the olden times, and its inconstancy, due to vagabond earth currents, at the present time has driven the instrument out of use as an instrument of precision. The voltameter becomes a current meter only after dividing its indications by the time that the current, which is to be measured, has flowed through it. A constancy of current during that time is pre-supposed. The voltameter is furthermore limited in range. Instead of either of these standards, a standard of electromotive force is now generally employed. It is the Clark cell, constructed according to the specifications laid down by the Chicago Electrical Congress.

In the measurement of resistances larger than 100,000 ohms, there is no practicable zero method. Over the wide range between this magnitude and 10 ohms, the Wheatstone bridge with adjustable resistances is to be recommended. Over the limited range of 10 to 300 ohms, the Kohlrausch pattern of the Kirchhoff slide wire bridge gives good results, if the wire is uniform and has been calibrated. Between 10 and 0.5 ohms the Carey-Foster method yields results that are beyond criticism. Smaller resistances than these can be measured by the Kelvin double bridge, the method of Matthiessen and Hockin, or the method of the differential galvanometer. The two first methods require a standard wire, and the last an instrument that has not received the attention that it deserves. The fact that it is now possible to obtain very small standard resistances of great accuracy furnishes a foundation for a method of determining these small resistances with great accuracy.

ELECTRIC LIGHTING.

STUDIES IN THE SPECTRUM OF REFLECTION.

BY DR. W. H. BIRCHMORE.

IN the issue of The Electrical Engineer for September 30, 1896, I gave in round numbers the total relative reflection areas of illumination of certain paper surfaces. I had intended to discuss quite another part of the subject in the present chapter, but my attention has been called to the fact that a part of what I have already written is obscure from lack of explicit statement, and as it is useless to build on an insecure foundation, I must to an extent retrace my steps. I explained, I think sufficiently, the nature of the factor called the "index of reflection," but I appear not to have made sufficiently clear its bearings on the matter in hand.

The figures of Meyer cover the lines B, D, E and G, and the immediate regions on either side, and it was not intended to say, except tentatively, that the waves between them followed the law of proportions, although until they have all been measured this forms an hypothesis both reasonable and workable. It should be remembered that it is an hypothesis; that this fact is admitted and that no claim has been put forward that it is anything more, and further his equations come very near to the measured quantities where other lines have been measured. To increase the number of lines and constants I have measured two sets in sunlight and the filament lamp, the regions of C and F. At C my quantity values give a curve slightly larger in area than Meyer's when sunlight is studied, and slightly smaller for the filament lamp. At F my quantities are greater than Meyer's should be for the filament lamp. Elsewhere the agreement is so close as to lead to the influence of instrumental differences or of differences in illumination.

There is one point which must be urgently considered. Was the amount of force made effective in the filament lamps the same in his experiments as in mine? Every one who has come in contact with the subject knows how difficult and how intricate this problem is, and it does not become any less tangled by further study. The great influence exercised on temperature and, therefore, on spectrum by small differences of current is as remarkable a phenomenon as any in the list. From this and certain experiments to be discussed later, I am inclined to think that the temperature of the carbon filaments in my lamps may have been, probably was, somewhat higher than those used by Meyer; which would, in theory, cause an increased relative blue emission in my lamps, which would agree well with that measured.

In this contribution I have made use of the Meyerian equivalents, interpolating my own to make the list of constants larger, This gives six series of points, instead of four, for each source of illumination, and is fully expressed as follows, the quantities given being the product of the index of reflection by the Meyerian equivalent.

SUNLIGHT.

Line in Spectrum.	B.	C.	D.	E.	F.	G.
Sample A	684	545	189.6	29.6	19	7.6
Sample B	259.2	165	63.7	36.5	22	7.6
Sample C	1,512	1,105	247.8	91.2	50	7.6
Sample D	1,540.8	1,215	481.4	67.7	38	7.6

ELECTRIC (FILAMENT) LIGHT.

Line in Spectrum.	B.	C.	D.	E.	F.	G.
Sample A	76	110	176.2	143.5	110	81
Sample B	28.8	52.5	94.7	176.6	132.5	81
Sample C	168	235	368.2	441.6	310	81
Sample D	171.2	340	715.3	327.5	205	81

It has been objected to the use I made of these figures that, as I placed them, they might "mislead those unfamiliar with the spectrum as to the relative quantities of light of different sorts reflected." If this be a possibility of the future, it is equally so of the past and must be corrected.

In my last contribution I suggest the plotting of the curves by the method of Angstrom and Thalen; I now strongly insist on the importance of this proceeding. This scale of Angstrom is an arbitrary one, as is that of Kirchoff and Hoffman, but it is independent of the instrument. It consists in giving definite linear expression to certain definite differences in wave length. My own method has been as follows:

Starting with the assumption that the lengths of the waves expressed by the nomenclature in common use are as follows: A = 0.76009 microns. B = 0.68668 microns. C = 0.65618 microns. D = 0.58920 microns. E = 0.52689 microns. F = 0.48606 microns. G = 0.43072 microns.

A micron is a one-thousandth part of a millimeter, and is the micro-millimeter, or small unit which is commonly designated by the Greek letter μ.

I used a machine divided scale of 1/16th inch for my scale as follows: The distance between 0.4307 and 0.4308 was assumed as infinitesimal, that 0.4300 and 0.4310 to be represented by 1/16th inch; consequently that from 0.4300 to 0.4400 would be represented by 10/16th of an inch. Such a scale is rapidly constructed, and at this scale the ability to plot runs the ability to see very close indeed, so that the errors are not vital, probably are imperceptible.

On such a scale the given lines are erected and the values given for the index of reflection into Meyer's equivalent laid off, using the same scale to represent a unit of 1/10th. Thus under Sunlight B, sample D, equivalent product 1,540.8, would be plotted as 154/16th of an inch, or 9 inches, and 10/16th, and the process continued until all the curves became graphics. Such curves then describe areas, which can readily be reduced and summed. Such a proceeding gives a much better notion of the differences in the location of the potential of illumination than any amount of description, or multiplicity of figures. Thus reduced and summed the relative illumination may be expressed as follows:

NUMBER OF AREA OF ILLUMINATION OF CERTAIN WALLPAPER SAMPLES.

SUNLIGHT.

Line of Spectrum and area.	Sample. A.	B.	C.	D.
B to C region....	187.5	64.4	399	420.5
C to D region....	245.8	76.7	453.5	568
D to E region....	68.4	31.3	99.6	171.5
E to F region....	10	12	28.9	21.6
F to G region....	7.4	8.2	16	12.6
Illumination	519.1	192.6	997	1,194.2

ELECTRIC (FILAMENT) LIGHT.

Line of Spectrum and area.	Sample. A.	B.	C.	D.
B to C region....	29.9	12.4	61.2	77.9
C to D region....	95.8	49.3	202	353
D to E region....	99.8	84.6	252	325
E to F region....	51.8	63.3	153.5	108.7
F to G region....	52.9	59.2	108.3	79.3
Illumination	330.2	268.8	777	943.9

If these figures be multiplied by 1,000 (10^3) they will express as near as may be by any at present available method the regional and actual reflections for illumination purposes.

It may be urged, and with some justice, that this method assumes a wider acquaintance with spectrology than actually exists; to avoid this criticism, I have reduced this to the colored regions by the following method:

It is, of course, widely known that no two human beings will agree as to the precise part of the spectrum when one color (so called) passes into another, but by a sort of common consent certain wave lengths have been agreed to as expressing these divisional lines. These may be considered either as classic, orthodox, or provisional, as the reader be inclined, if well acquainted with the instrumentation the wave lengths and not the colors are important; if used to the more obvious but less precise method the accuracy of the division is sufficient to serve the need.

The wave lengths assumed are as follows: Between red and orange, 6,460; orange and yellow, 5,945; yellow and green, 4,895; green and blue, 4,600; blue and violet, 4,307.

If the suggestion of plotting the curves has been carried out these divisional lines can be readily drawn in and thus the colored regions located, with sufficient accuracy for all practical purpose.

The ordinates can be measured from the curves and used as a means of obtaining the areas, or the ordinates can be calculated from the equations of the curves, or best, the ordinates can be measured by photometric measures for the given wave lengths.

This last method is undoubtedly the proper one, but it implies instruments, skill, patience and an abundance of time; to the average reader direct measure is recommended. This method wil come near enough for all ordinary uses, and will, if comparison only is intended, be equally satisfactory, may be more so, with the laborious one which the investigator of such phenomena must perforce use.

Table giving expressions for the Illumination Values of the Samples in terms of the "colors of the rays" is as follows:

SUNLIGHT.

Colors.	Sample.	A.	B.	C.	D.
Red	6,869—6,460	231.5	91.8	491.5	527.5
Orange	6,460—5,945	169	55.3	306	394
Yellow	5,945—5,352	63.2	31.4	121.5	187.5
Green	5,352—4,895	17.5	14.9	56.2	51.3
Blue	4,895—4,600	5.3	5.3	13.3	8.9
Violet	4,600—4,307	2.6	2.6	5.6	4.1
Illumination		489.1	201.3	994.1	1,173.3

ELECTRIC LIGHT.

Colors.	Sample.	A.	B.	C.	D.
Red	6,869—6,460	39.1	17.2	82	148
Orange	6,460—5,945	84	59.7	165	275.5
Yellow	5,945—5,352	71.1	100	239	316.5
Green	5,352—4,895	61.1	73.3	175	142
Blue	4,895—4,600	28.4	35.4	75.4	52
Violet	4,600—4,307	25.2	27.2	37.5	32.2
Illumination		308.9	312.8	773.9	966.2

These quantities multiplied by the same factor, 10^6, will give the ratios within a reasonable limit as before.

It will be at once noticed that these figures do not agree with those of the previous table in summation. It would be very remarkable indeed if they did; such an agreement would probably be only an accident, and would throw, in my own opinion, doubt upon the competency of the whole work. As they stand, they express the result of a certain amount of labor, the discussion of certain observations and this alone.

Undoubtedly as data accumulate sources of error will be discovered, errors in observation will be checked and eliminated, and in process of time the two summations will agree. But before any such agreement could be accepted as satisfactory, to my own mind, not days, but months of work must be added to the total already expended.

In discussing the results it will make small difference which series of figures are used, as suggestion, not instruction, is the purpose of my work. It is not my wish to set up landmarks, but to incite others to explore, and if I have managed to fill in a few "lakes and mountains" I have succeeded in my ambition; future journeys can connect the lakes, so be they join, and map the mountains and valleys between them.

AUTOMATIC SWITCH FOR CHARGING ACCUMULATORS FROM AN ARC CIRCUIT.

BY EDGAR KIDWELL.

THE writer has at times needed an automatic switch for charging storage cells from an arc circuit, but failed to find in the market anything answering his particular needs. He therefore worked out the instrument here described. It has been very satisfactory to him, and may perhaps be of use to others.

The problem was to so design the instrument that in case one wished to charge during the hours when the arc service is in operation, he would need only to throw his main switch at any time during the day, leaving to the automatic switch

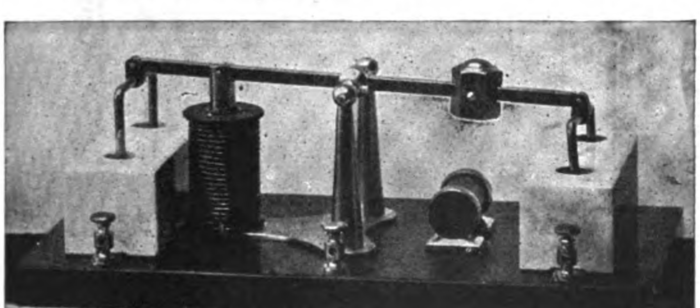

FIG. 1.—KIDWELL AUTOMATIC CIRCUIT BREAKER FOR CHARGING STORAGE BATTERIES FROM ARC CIRCUITS.

the task of turning the current into the cells at the proper time, keeping the line circuit always intact, yet promptly breaking the cell circuit whenever the dynamo stops, or in case of any breakage of the line. The writer thinks it unwise to subject a battery worth over $1,000 to the danger of discharging through the line, in case of accident, or neglect to keep station switches open.

The instrument is shown in Fig. 1, and its connections in Fig. 2. G, H, and K are binding posts. To opposite ends of the lever shown in Fig. 1 are attached U-shaped copper connections, which drop into mercury cups, aa, and bb. It is clear that if path A is closed, and B is open, the line is intact, and cells are cut out. If path B is closed, and A is open, charging

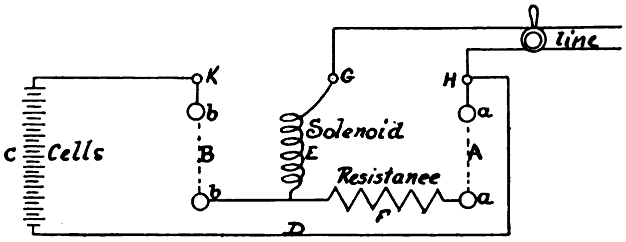

FIG. 2.

of cells will proceed. The counterweight on the lever is adjusted so that A remains closed until current in line (maximum strength, 6.8 amperes) rises to 3 amperes, then solenoid E acts on the plunger, tilts the lever, opens A, closes B, and charging proceeds until current drops to 3 amperes, whereupon the cells are cut out.

It is, of course, inadmissible to open the main circuit for an instant, hence it is clear that the height of the mercury in the cups must be such that B is closed before A is opened, and vice-versa. Hence it follows that during the act of switching

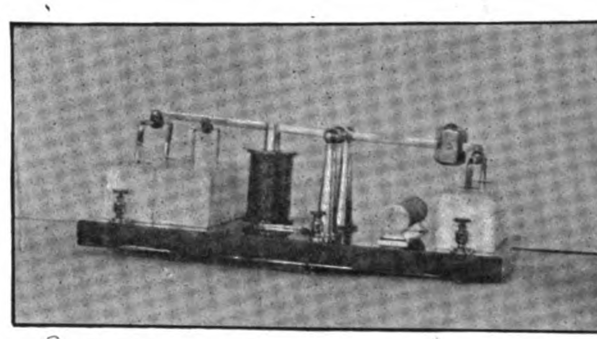

FIG. 3.—THE KIDWELL AUTOMATIC SWITCH.

both A and B must be closed during an interval of time depending on the rapidity with which the current in the line rises or drops as the dynamo is started or stopped. During this interval the line current is traveling via G F A H, and the cells are short-circuited through path K C D H A B. Unless some resistance be placed in the latter path, the cells will be quickly destroyed by the sudden excessive discharges, hence at F is placed a non-inductive graphite resistance such that during the time of short circuit the cells cannot discharge a current greater than 25 per cent. of their maximum safe

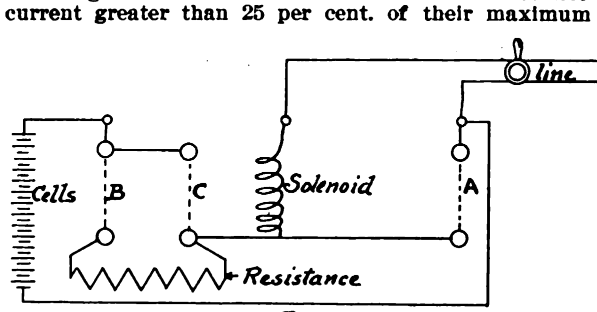

FIG. 4.

capacity. It is clear that with solenoid set to act at 3 amperes this resistance is switched out of the line before the lamps strike their arcs.

By arranging apparatus as in Figs. 3 and 4, an ordinary form of resistance frame, even if it has considerable self-induction, may be used in place of the graphite resistance. Three pairs of cups, at A, B and C, are used, the only precaution to be observed being that the height of the mercury in the cups must be such that when the lever tilts, B is closed before A is opened, then A is opened, then finally C is closed. The path of the current at each stage can easily be traced out.

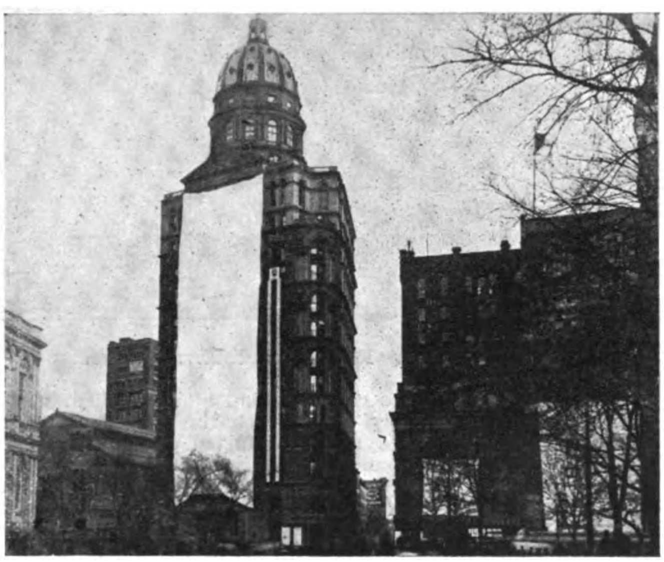
The writer takes pleasure in acknowledging his obligations to the Automatic Circuit Breaker Company, Newaygo, Mich., who built the instrument from his sketches, and to whom all credit for the mechanical details is due.

ELECTRICITY IN THE RECENT POLITICAL CAMPAIGN.

BY THEODORE WATERS.

THE political campaign of 1896 will be memorable in the time to come for reasons other than those embraced by its party and financial interests. In addition to the remarkable victory for sound money another triumph has been scored. In more ways than one the recent contest has shown how absolutely dependent we are upon electricity for the successful promulgation of all great modern social improvements. Everywhere during the campaign the current was used in some manner, direct or indirect, to enhance the enthusiasm or to further the business interests of the political managers. The telegraph and telephone in the day time; the electric lamp at night, were kept going constantly. Some stupendous figures were deduced in the first place and some wonderful engineering feats were accomplished in the second. Of the first we shall speak elsewhere. Of the second there is an interesting tale to be told.

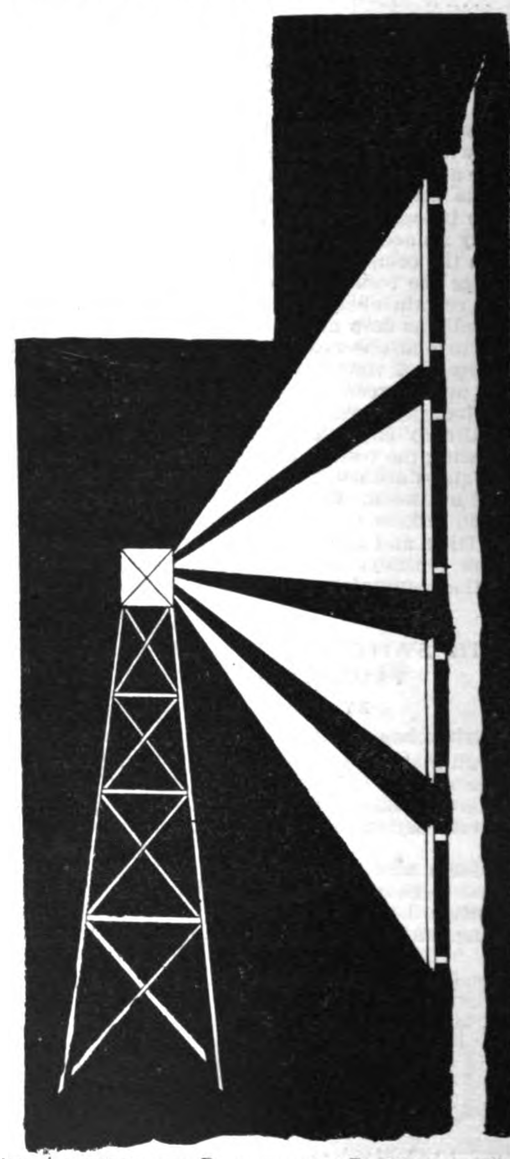
In New York City, where great financial and industrial interest were at stake, the excitement was intense, and of course the large daily newspapers of the metropolis vied with each other in an effort to present the returns of the election to their constituents in as striking a manner as possible. The New York "World" made arrangements to flash the news of the election by means of search lights placed high up in the great dome of the "World" Building. The dome was also lighted as usual with incandescent lamps, and colored lines of light were used to signal the result to the people of the city far and wide. For those persons who were more desirous of



THE WORLD BUILDING READY FOR THE ELECTION RETURNS.
Copyright, Nov. 7, 1896.
FROM A PHOTOGRAPH BY J. B. COLT & CO.

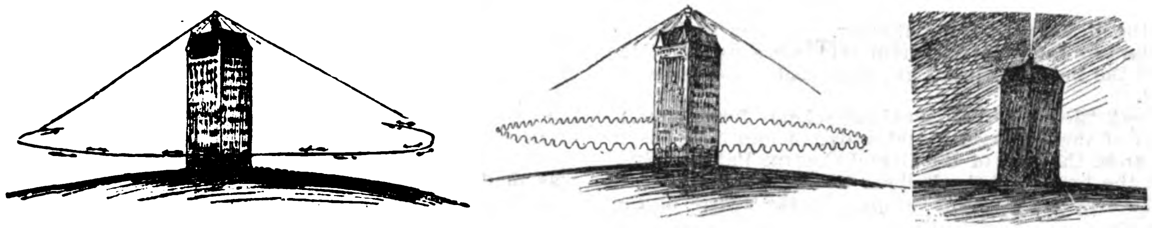
learning the details of the election, stereopticon exhibits were arranged. The whole front of the "World" building was covered with an immense canvas screen 180 feet high and 60 feet wide. Upon this six immense disks of light were projected. The projectors were operated from a tower 40 feet high, stationed in City Hall Park, 145 feet from the building. The electrical features of this tower were very interesting. The projecting lanterns were of the Criterion type manufactured by J. B. Colt & Co., of 115-117 Nassau street, New York, and were operated of course by an electric current. The tower was in a measure a central station, situated high in the air and getting its supply of current from two large mains which were connected to the private lighting plant in the "World" building, and which were strung through the air from an upper story window of the building. The tower was equipped with a switchboard and controlling rheostats. Each lantern had its individual rheostat and was in no way dependent upon the others. The installation had almost the appearance of a permanent plant and might have been maintained as it was for any length of time. The news as it was received in the "World" building was relayed to an extra telegraph receiver in charge of an operator stationed in the tower. Previous to the time when the returns were received, the lanterns were used to project various edifying scenes upon the canvas, much to the amusement and delight of the crowd. The two upper circles of light upon the canvas were 60 feet in diameter each. The four lower circles of light were 30 feet in diameter each. About 40 amperes of current were used upon each upper disk and about 30 amperes were used upon each of the lower disks. 5-inch condensers were used, with ⅝-inch soft-cored carbons. The calculated illumination of each disk was 10,000 candle-power. An ordinary voltage of 110 was employed. The World also had a 25x50-foot screen on the front of the Union Dime Savings Bank, at Thirty-second street and Broadway. On this screen there were two disks of light 25 feet in diameter each. "Criterion" lanterns were used here also, under about the same conditions as those used further downtown.

It is worthy of notice that this is by far the largest projection ever made, either here or in Europe, and the screen is also by far the largest ever constructed for such work. All of the work was under the personal direction of Mr. R. C. Daniels. We illustrate herewith the methods used, and are indebted to J. B. Colt & Company for great kindness in furnishing the details and material of illustrations.



STAND FOR LANTERNS AND PROJECTION OF RETURNS ON WORLD BULLETIN BOARDS, NEW YORK PRINTING HOUSE SQUARE.

The New York "Times" and the New York "Journal" also operated a stereopticon in front of their respective buildings. It may be remarked however, that these plants differed from the plant in front of the "World" building for the reason that a three-wire system was used in place of a two-wire system. The latter was necessary in the case of the "World" plant because the private installation in the "World" building is of the two-wire variety. In the tower erected by the New York "Times," in Park Row, five Criterion stereopticons were used, throwing five disks of light on a 42-foot screen. The tower was only 18 feet high. This necessitated a very acute angle of light being thrown upon the screen. The "Times" also had a display at Twenty-third street and Broadway. Here two disks 20 feet in diameter and two lanterns were used. The New York "Journal" used four lanterns in a tower



CIRCULAR SWEEP—MCKINLEY. WAVY BEAM—BRYAN. VERTICAL BEAM—IN DOUBT.

METHOD EMPLOYED IN CHICAGO OF INDICATING ELECTION RESULT FROM MASONIC TEMPLE BY SEARCHLIGHT.

erected in front of its office in Park Row. The ordinary 110-volt three-wire system was used. About 20 amperes were used on each disk. A remarkable feature of the "World" tower stationed at Thirty-second street was its having three

METHOD OF DISPLAYING ELECTION RETURNS ON CITY HALL SQUARE AND PRINTING HOUSE SQUARE, NEW YORK.

Copyright, Nov. 7, 1896.

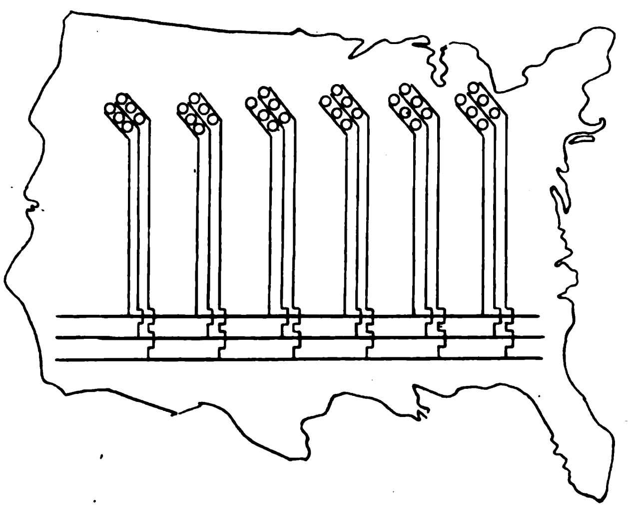
(APPARATUS OF J. B. COLT & CO. FROM A PHOTOGRAPH TAKEN BY J. B. COLT & CO.)

stories. The two lower stories were used for the operation of Criterion lanterns. The top story was used to operate the "Biograph," which, during the early part of the evening, projected its moving pictures upon the disks which were afterwards used for election returns.

The New York "World" also made arrangements to flash signals of electric light from various high points in New York and Jersey City. A searchlight was operated on the high tower of the Manhattan Life Insurance building, from the tower of the Siegel-Cooper Company's building, from the roof of the Rushmore Dynamo Works, in Jersey City, and from the high eminence at Fort George, on the northern end of the island. The light from the Siegel-Cooper Company's tower was distinguished at Poughkeepsie, more than seventy-five

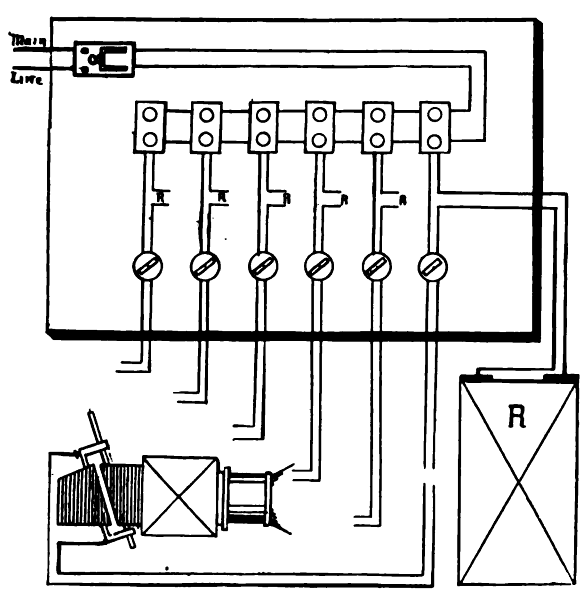
miles away, the night being fine and clear. Fourteen Rushmore naval projectors of the most powerful type were used in Jersey City, and the flash of their light was visible for miles in all directions.

The New York "Journal" had a unique scheme for transmitting the news of the victory far and wide. A captive balloon was sent up from the roof of the Grand Central Palace. Suspended from the basket of the balloon was an immense star, composed of white incandescent lamps. In the centre of the



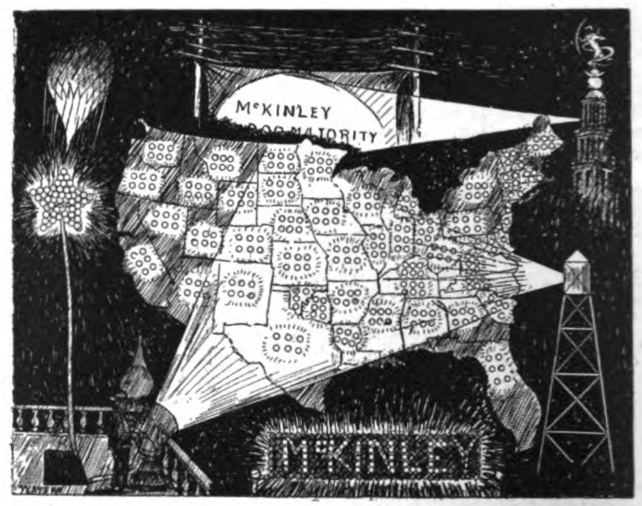
Circuits for Lighting Indicator Red and Green Lamps on the Map.

white star were a number of green and red lights intermixed. At the proper moment the red or green lights were to be flashed, each color corresponding to the successful political organization. As a matter of fact, the green, denoting the Republican victory, was used alone. The lamps were operated from a switchboard in the building and the current was carried from the local plant by a heavy cable, which also served the useful purpose of securing the balloon to the roof of the building. The illumination was very effective. Another scheme which the "Journal" put in operation was a map of



Circuit and Arrangement for the Colt Lanterns on the World Stand.

the United States, which was stretched over the lower portion of the "Journal" building, and on which the name of each State was to be illuminated in either red or green lamps, accordingly as each State went Republican or Democratic. The erection of this map was something of an engineering feat. The scheme was not conceived of until two days before election. It was painted, erected and the electrical installation made in time for a successful display. The three-wire system was used. There were three red and three green lights for each State. The neutral wire, of course, occupied a position between the two rows, and before the returns were received it was permanently connected to the neutral main, which extended across the building just back of the map. As the result of each State election was received, the leg, or wire corresponding to the red or green row of lamps was quickly attached to its corresponding main, and thus the installation was made temporarily with as little trouble as possible. It may be remarked that no accidents of any kind were en-



Map, Balloon, Star and other Effects, with Electric Light, Election Night.

countered. The whole affair was torn down within a few hours after it was used.

The New York "Herald" made use of the beautiful Madison Square Garden tower to flash the result of the election around the city by means of powerful naval projectors. As a matter of fact, the clear, cold atmosphere above New York City was being constantly illuminated in all directions by the dazzling shafts of light which were projected from many high towers. The cinematograph, the biograph and the vitascope were used in several parts of the city by the various newspa-

Search Light on Dome of Manhattan Building.

pers to amuse the crowd during the evening before the election returns were received. All the theatres were illuminated and many of them furnished the returns by means of projecting lanterns with screens stationed temporarily upon the stage between the acts. Many of the high buildings were illuminated, of course, and, in fact, everywhere it was evident that wherever it was obtainable the electric current was thought to be the proper thing for celebrating the election.

The large screen of the New York "Tribune," adjoining that

of the "Journal," on Printing House Square, was operated by means of the hand-feed Bijou lamp, with single Institute stereopticon, furnished by Mr. Charles Beseler, of Centre street, New York City. Great fun was created by the rapid exchange of remarks on the "Tribune" and "Journal" bulletin boards, the former being Republican and the latter Democratic. The same Beseler apparatus was furnished to the Detroit (Mich.) "Journal" for its election return work.

In Chicago, the same free resort was made to electricity. The Chicago "Record," for example, took possession of the top of the tall Masonic Temple, and by means of a General Electric searchlight, gave out the news of the result far across the tumultuous city and the waiting prairies. The plan is here illustrated. The election of Mr. McKinley was illustrated by means of a steady horizontal sweep of the beam of light from left to right and right to left. Had Mr. Bryan

SIGNAL OF VICTORY WITH FOURTEEN SEARCH LIGHTS, FROM RUSHMORE FACTORY, JERSEY CITY.

won the light would have had the staggers, and had the result been in doubt an appealing finger would have been raised to the heavens for a righteous decision. The Masonic Temple dome is 324 feet above the level of the street, and current was led up to the light by special cables from the plant in the basement of the building.

Various details were given in The Electrical Engineer last week as to the work done specially by the telegraph and telephone in handling the election returns. Further reference is made to that part of the subject in the editorial comment this week.

MYSTEROUS BREAKDOWNS OF INSULATION.

BY PROF. ELIHU THOMSON.

APROPOS of the editorial in The Electrical Engineer of October 21 on "Mysterious Breakdowns in Insulation," it will be recalled that formerly the practice in insulating electrical apparatus was to make the insulation sufficient to stand the working potential, whereas nowadays the practice is becoming more general to test the insulation of apparatus by submitting it to strains of very much greater amount than that which is likely to exist in practice with the apparatus, giving a condition similar to that secured by the "factor of safety" which is always used in mechanical construction. At the same time a large measure of attention is now being given to the examination of insulating materials, of which we have none too many with the properties which are desirable.

The more general use of mica as a constituent of insulation has, of course, had its good effects where the peculiar characteristics of mica as an insulator were needed, and it is now the practice in the best equipped establishments to test the insulating qualities of all materials before making use of them. I think, therefore, that the great improvements which have been, up to this time, shown in the methods of electrical construction, particularly in view of the enormously increased demands which have grown during the same period, are an indication that in the future mysterious breakdowns will be more rare than in the past.

It must not be forgotten that the voltage of circuits has been gradually increased, the sizes and capacities of machines enormously multiplied, and that during all this period improvements in manufacturing and insulation have been going on by the "weeding out" process; that is, by eliminating weaknesses wherever they have shown themselves. When one thinks of the development of the street railway motor alone and what was necessary to keep it in repair during the first year or two of its existence, as compared with the repair bill now, there is room for any amount of encouragement. At the same time, the cars which are propelled are much heavier and run at greater speed, the braking and stoppage of motion is more sudden, due to improved braking appliances, and yet the motor is, of course, not perfect, though it is difficult to say in what direction any very great advance can be made.

While I agree with the Engineer's remarks in general about the sudden rupture of electrical circuits having a tendency to find the weak spots in electrical machinery, resulting in breakdowns, yet it must be borne in mind that the sudden or gradual rupture of a circuit is not always a matter of choice, for there may accidentally happen a sudden rupture of the circuit without our intending it; thus, a trolley may slip off the wire and suddenly rupture the circuit through the motors on the car; the car may become derailed and thus rupture the circuit; storms may cause lines to be torn down by objects falling upon them and cause sudden ruptures, all of which accidents, if they are to be attended with the breaking down of the dynamos or motors, are made all the more disastrous.

My own feeling is that we shall continue to improve the conditions of installation and the quality of insulation and that sufficient safeguards will be provided for the most sudden rupture of circuits which may be made, and it is to the use of these proper safeguards that I look for the preservation of the machinery from injury. It is true that when a short circuit occurs on the line, conveying enormous energy of current, the quicker a rupture can be made the better, so that the current may not grow to such proportions as to produce damage. This may not be so decidedly the case with alternating currents as with direct, but I think that the safety of the apparatus can be assured, even in the cases of the most sudden rupture, by proper provision of such devices as are employed in the case of lightning discharges. Did we not, in fact, have lightning to contend with as an element of risk of breakdown, it is doubtful whether our improvements in insulation would have been as rapid as they have been. The provision of discharge protectors or lightning arresters is for the express purpose of preventing the insulation of the machine being strained beyond a certain limit, which limit it is supposed to easily stand, and if well constructed generally does stand.

As an instance of what I mean I may say that in our early experience with welding machinery we found that it was entirely beyond our control to prevent occasional ruptures of the heavy current in the secondary circuit, and that this rupture, reacting on the primary of the welding transformer, of course resulted in the production of an enormous voltage, such as would easily leap a considerable fraction of an inch in air. To provide against all possibility of damage from this cause to generators and to transformers, we provided a discharge protector, in a measure similar to a lightning arrester, which was found to be perfectly effective for the purpose, so that no difficulty was ever after experienced from breakdowns of insulation due to sudden rupture of the secondary circuit.

It is my opinion that by employing this principle more largely in electrical installations, the particular elements of danger which you comment upon could be nearly removed, while the improvement in the insulation and the testing of the insulation, conjoined with a proper and intelligent care of the machinery itself (which is naturally often more delicate because it is electrical) will do the rest. I think, also, there is going to be a better understanding on the part of people who have charge of electrical machinery, of just what must be avoided to save the machinery from injury. For example, nothing could be worse for an electrical station than to have it lie idle and the machinery become cold, and subsequently thereto to have a warm humid atmosphere surround the comparatively cold machines. This would lead to the condensation and absorption of moisture, and I have no doubt much trouble has resulted from the existence of such conditions. Incidentally, I may say if street railway managers knew salt to be such a deadly enemy of insulation as it is they would never use it on their tracks.

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—VI.

BY LIEUT. B. A. FISKE, U. S. N.

THE SPEED AND DIRECTION INDICATOR.

THE office of this apparatus is to indicate at a distance the speed and direction of revolution of the shaft of an engine, or any other shaft.

The underlying idea is an apparatus which is actuated by the shaft, but has no mechanical connection to it, which operates entirely by itself, and without intervention or care from any outside source; and which has no belting, or gearing subject to slipping, or to wearing out in service.

The speed indicator (direct reading) consists, broadly speaking, of an alternating current system, in which the alternating currents are induced by the rotation of the shaft, being great or small according as the shaft moves rapidly or slowly; and of an alternating current indicator, which indicates the magnitude of the current, and therefore the speed of revolution.

The direction indicator consists also of an alternating current system actuated by the motion of the shaft.

The apparatus is shown in Figs. 18, 19, 20, 21 and 22. Fig. 18 shows both circuits connected to their respective indicators. Mounted on the shaft are two rings, C and C'. Each ring is in halves, which fit the shaft, and these are clamped on, as shown, by lugs at D and D'. (See also Figs. 19 and 20, in which Fig. 19 shows the part pertaining to the speed indicator and Fig. 20 shows the part pertaining to the direction indicator.) Secured on the ring D, or rather on a web that is cast on ring D, are, say, six soft iron inductors, I. These inductors, when revolved by the shaft, pass in front of the poles of the magnet S N. On the poles of the magnet S N are two coils of wire, and these are connected to the alternating current indicator G. When one of these inductors, I, is directly in front of the poles S N, the magnetic flux passing through the two coils is at its maximum. When no iron inductor is near the poles S N, the magnetic flux is at its minimum. As these iron inductors revolve before the poles, consequently the magnetic flux is increased and decreased as many times per revolution as there are inductors. Each increase and decrease of the magnetic flux produces an alternating current in the coils, according to principles well understood, and the more rapid the increase and decrease, the greater the electromotive force induced. It is evident that, in manufacture, it is possible, with a proper construction of the apparatus and with a proper proportioning of the parts, to so control the inductance of the circuit, and to so arrange the inductors and the number of them, that the current in the circuit shall increase very considerably as the speed of the rotation of the shaft increases. In the drawings, the magnet S N is shown as a permanent magnet. Of course it can be an electro-magnet, if desired. If a permanent magnet, the steel must be specially hardened, in order that it may not lose its magnetic strength with age.

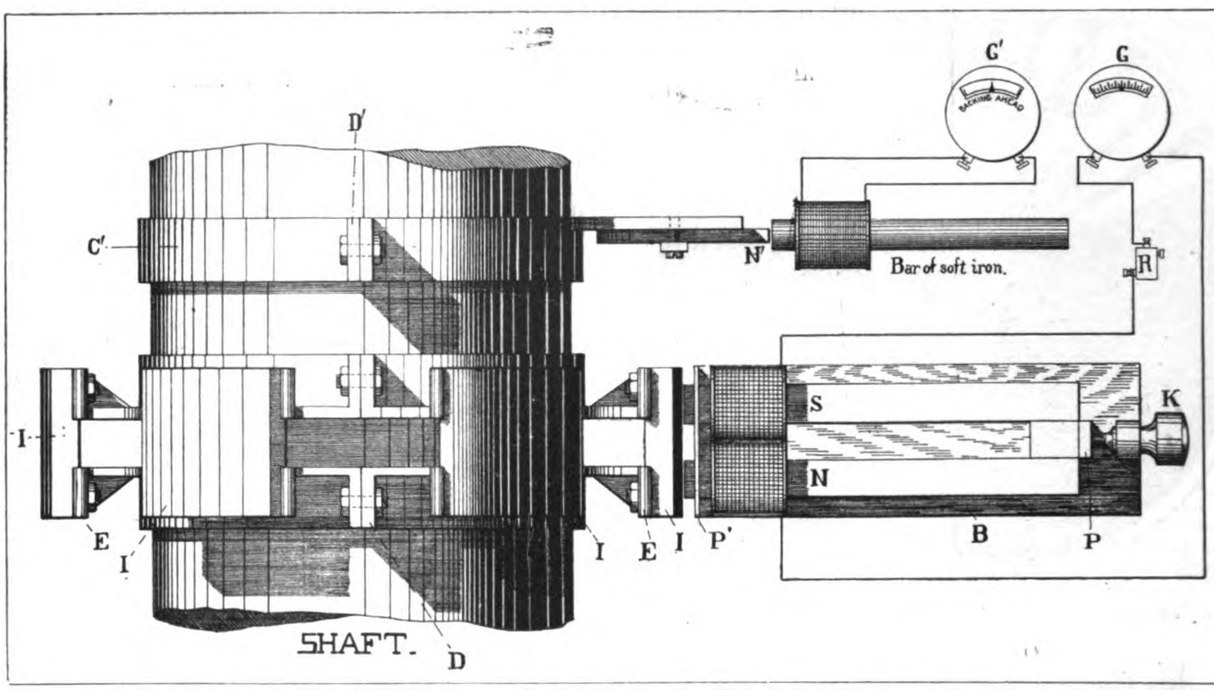


FIG. 18.—LIEUTENANT FISKE'S SPEED AND DIRECTION INDICATOR.

It is advisable, in the construction of the apparatus, to introduce an adjustment for controlling the air gap between the inductors I and the magnet poles N S, and, therefore, the magnetic flux and the strength of the current generated. The adjustment is accomplished by mounting the magnet S N on the two supports P and P', Figs. 18 and 19. By turning the screw K in one direction or the other, the magnet poles are moved longitudinally in the stationary support P', and moved closer to, or further from, the inductors, thus increasing or decreasing, at will, the strength of the currents generated. The usual distance is about 1-16-inch. In installing the apparatus, it is merely necessary to adjust the distance until G indicates correctly.

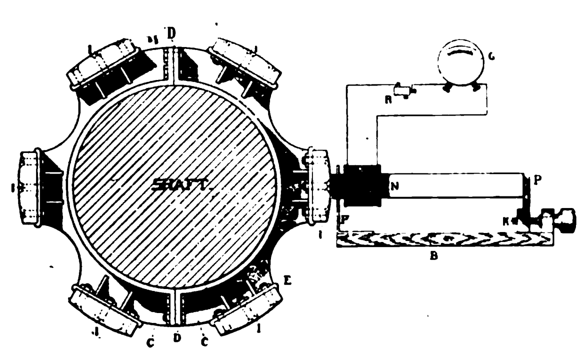

FIG. 19.—LIEUT. FISKE'S SPEED AND DIRECTION INDICATOR.

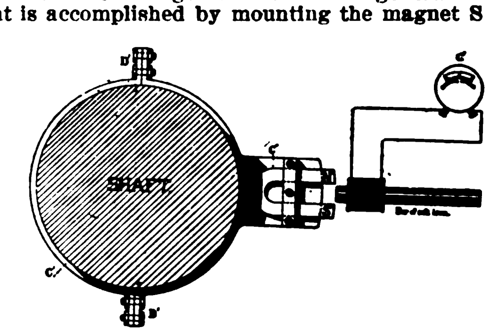

FIG. 20.—SPEED AND DIRECTION INDICATOR.

For making smaller adjustments, the rheostat box R may be mounted near the indicator G. This rheostat box is of the general type used in the range-indicator, and consists, broadly speaking, of a resistance wire wrapped around the surface of an insulating cylinder, so arranged that, by revolving the cylinder, a greater or less amount of resistance may be introduced in the circuit. This adjustment is not always used.

The graduations of the galvanometer G are made empirically

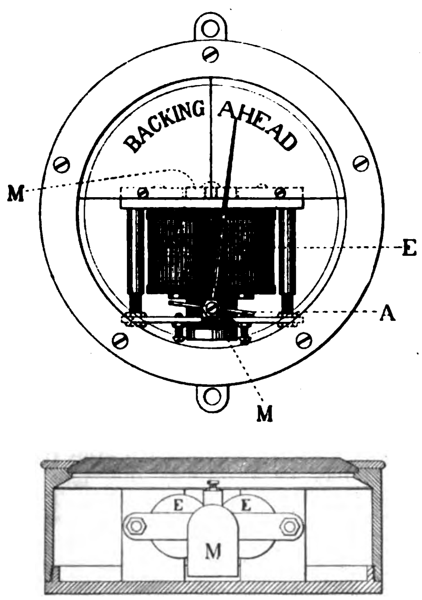

FIG. 21.—LIEUT. FISKE'S DIRECTION INDICATOR.

in manufacture. A shaft carrying the inductors I is run at the various speeds, and the scale of the indicator G is marked with the proper numerals at the places at which the needle stands.

When the speed indicator is mounted on board ship the electrical apparatus of the indicator may be mounted in a water-tight case filled full of a liquid in order to steady the needle. Doubtless many different liquids may be used. Poppy-seed oil is satisfactory; but alcohol mixtures dissolve the shellac on the wire. The galvanometer case is filled from the top, by pouring the liquid through a sort of stand pipe P, Fig. 22, in which it stands at a height somewhat above the case itself. The filling hole in the pipe is closed by a screw plug, and in

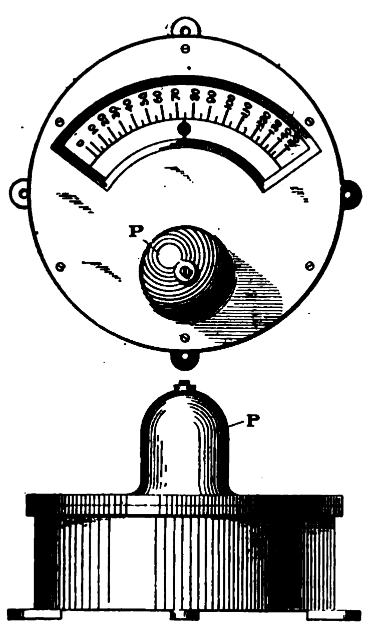

FIG. 22.—SPEED INDICATOR.

this plug is a small hole, which allows the passage of air into or out of the pipe, as the liquid contracts with cold or expands with heat.

The alternating current galvanometer, which is ordinarily employed, is not very different from the direct current galvanometer shown in Fig. 6. But the permanent steel magnet is replaced by a stationary coil of wire which is in series with the movable coil or bobbin. Whenever the current changes in direction, it changes in direction in both the stationary and the moving coil, so that the direction in which the moving coil turns, due to mutual reaction between the two coils, is always the same. Two pairs of volute springs, similar to those in the direct current galvanometer, keep the moving coil, and therefore the needle, at a certain normal position of rest. But any current traversing the coils moves the coil against the springs

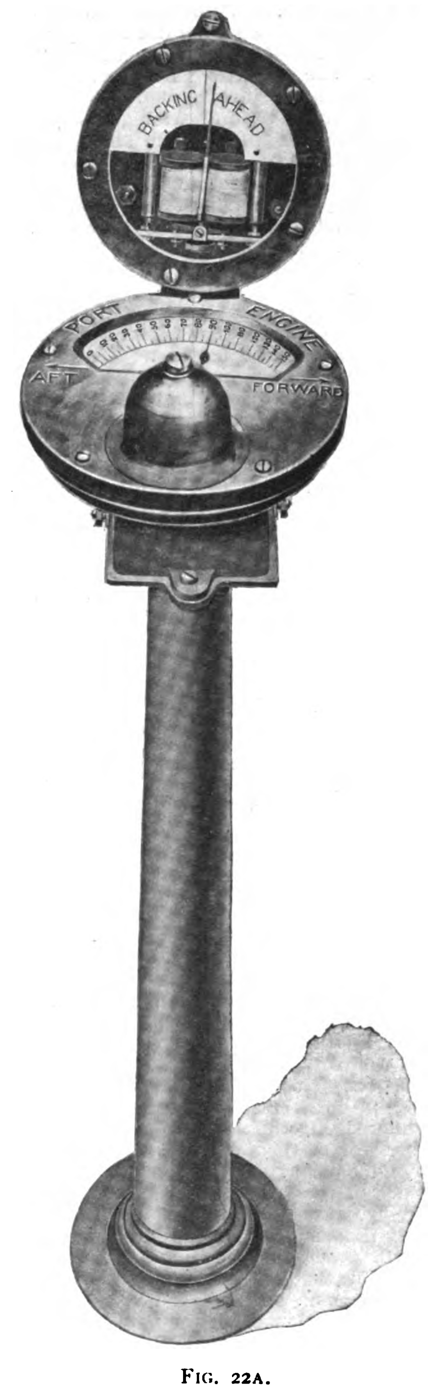

FIG. 22A.

through an angle which depends on the strength of the current.

That part of the apparatus which shows the direction or revolution is shown in Figs. 18, 20 and 21. The magnet N′ S′ is mounted on a projection, C″, secured to the band C′, which is secured on the shaft by means of lugs and screws D′. Mounted near the path traced by the poles N′ S′ in revolving, is a bar of soft iron, on which is a coil of wire connected to a direct current galvanometer, polarized relay, or other current indicator G′, in which a current in one direction causes the needle, or pointer, to move in a certain direction, while a contrary current causes it to move in the opposite direction. Sup-

pose that the shaft is revolving in the direction of the hands of a watch, and that the pole S' approaches the bar of soft iron until directly opposite to it. The approach of this pole will, of course, induce a current of a certain direction in the coil, which current will cause the needle, or pointer, to move, say, to the right, with a quick motion. As the shaft continues to revolve, the pole S' leaves the bar of iron and the pole N' comes up to it. This act induces in the coil a current opposite in direction to that induced by the approach of the south pole, and tends to give the needle, or pointer, a movement, say, to the left. The revolution of the shaft continuing, draws the N' pole from the bar of iron, and this act induces another current in the coil in the same direction as did the approach of S' pole, and, therefore, another movement of the needle, or pointer, say, to the right. The result is, therefore, that at every revolution of the shaft in the direction of the hands of a watch, the needle, or pointer, of the indicator gives quick movements, say, to the right, left, right. If the shaft is moving in the reverse direction, the state of affairs produced is just the reverse of that above cited; so that at every revolution of the shaft, the needle or pointer of the indicator makes quick movements, say, to the left, right, left. By merely looking at this indicator, therefore, an observer sees at once in which direction the shaft is revolving, and he sees also when each revolution takes place. Not only this, but the observer, when he has leisure, can count for one minute the movements of the needle or pointer of G' and see what was the number of revolutions actually made in the minute. The direction indicator is, therefore, a speed indicator also, and may be used as such in case of accident to the direct reading instrument, in connection with which it may always be employed, moreover, as a means of verificaton.

Fig. 21 shows a "polarized relay," such as is used for ringing magneto bells, adapted as a direction indicator. The armature A, polarized (magneitzed) by the permanent magnet, M, is pivoted between the two poles of the electro-magnet E. The alternating currents generated pass through the coils of this electro-magnet and tend to give the armature successive movements right, left, right, or left, right, left, at each revolution. And since there is no directing spring on the armature, and since the magnetized armature when moved to either side tends to remain there, by reason of its nearness to one iron core or the other of the electro-magnet E, the armature remains during the whole time of a revolution, except when the magnet N' S' is actually passing the soft iron bar and its coil, at the position in which it was placed by the last current. In other words, the armature has a certain position of rest which it occupies throughout nearly the whole of a revolution, and which is the position in which it is placed by the last current of the three which are induced by the passage of the magnet N' S' in front of the soft iron bar and its coil.

Furthermore, as the last current, when the shaft is going in one direction, is the reverse of what it is when the shaft is turning in the opposite direction, this position of rest is on one side or the other of its middle position, according as the shaft is going ahead or backing; and as the first current generated in any revolution is the same as was the last current, and as the armature cannot move any farther, the first motion cannot take place except during the first revolution of the shaft.

The result of all this is, that, if the shaft be going ahead, the pointer of the direction indicator, which is attached to the armature, will occupy a position of rest on one side of the scale and will make a quick motion to the left and back at each revolution; whereas, if the shaft is backing, the pointer will lie on the other side of the scale and will make a quick motion to the right and back at each revolution.

The two sides of the scale are marked "Ahead" and "Backing" respectively, as shown in Fig. 21.

The copper wires used in the circuits should not be less in size than No. 16 American gauge.

The speed indicator has been in successful operation on board the U. S. armored cruiser New York for about eleven months, and the direction-indicator in the same ship for about six months. Both are now being installed in the battle-ship Texas, showing in the conning-tower the speed and direction of revolution of both engines; and they are to be installed in the Brooklyn.

RULES FOR SUBURBAN POLES IN WASHINGTON.

The U. S. Commissioners for the District of Columbia have formulated the following order for the overhead system of the Potomac Electric Power Company West of Rock Creek: Poles shall be at least 45 feet high. No span shall be greater than 125 feet. Poles are to be set 9 inches from the outside face of the curb.

All poles are to be stamped or branded with the initials of the company and with number of the pole, not less than 5 feet nor more than 7 feet above the ground.

Cross-arms shall be uniform in length, strengthened by braces, and all wires shall be attached thereto with glass, porcelain or rubber insulators, and must be stretched tightly and fastened with strap of the same kind of wire.

All wires shall be continuously insulated with durable and waterproof material, and this insulation is to be carried to all portions of the circuit, including joints, and is to be kept in constant repair.

No wire shall be stretched within 4 inches of any pole, building or other object without being attached thereto and insulated therefrom.

No line of 500 volts or over shall hang within 20 feet of the surface of the ground at the lowest point.

Every line, pole, fixture, etc., must be kept in order and repair in conformity with these regulations; but no additional poles or wires can be erected under cover of repairs, nor shall the route or location be changed without a permit.

The company shall, upon completion of the overhead line, file with the engineer department plats showing the exact location of the poles and the number and character of the wires strung thereon.

ELECTRIC HEADLIGHTS ON CROOKED ROADS.

The merits of the electric headlight have long since been made familiar, says the "Railroad Gazette." Besides the main function of the light—to illuminate the road for the runner of the engine which carries it—it is a peculiarity of the brilliant arc light, backed by a powerful reflector, that it gives early notice to station men, wayfarers, runners of other trains, tramps and rabbits of the approach of the train bearing the light. In a number of instances this has been strikingly illustrated in the prevention of collisions. The runner using this light cannot see through a hill or a building any better than without it, but by shining above the hill or building the light will make its whereabouts manifest several miles in advance, so that other trains can know that the electrically-lighted train is approaching. The illumination of the particles of dust or moisture in the atmosphere makes a pencil of light which, if the angle of the reflector is properly adjusted, may be seen in the air overhead many miles away, and this often makes an intelligible indication to runners of other trains even if, by reason of a curve in the track between the observer and the point where the light is at that moment, the pencil is some distance away from the line of the road.

Mr. R. C. Vilas, of the National Electric Headlight Company, has recently received a letter from the General Manager of the Cincinnati, Hamilton & Dayton recounting an instance illustrating the value of this feature of the light. An engineman running empty at night, and with the tender foremost, forgot about a passenger train that was due, and would have met it on the bridge over the Miami River at Hamilton, but he saw the light from the electric headlight of the passenger train before the train was in sight; that is, before it had reached a point where it would have been in sight by daylight, or where the lamp could be seen. The careless engineman at once stopped and succeeded in getting into a sidetrack before the passenger train reached him. This was on a road which is by no means free from curves. With the reflector adjusted at such an angle as to throw some of the rays slightly above the horizon the pencil of light in the sky may be made to pass above all ordinary hills and other obstructions, and thus make the light valuable on a crooked road as well as on straight lines. Enginemen on the Cincinnati, Hamilton & Dayton, as well as on the roads of the Western prairies, assert that they would pay for the lamps themselves rather than do without them.

FAREWELL REPORT OF THE BROOKLYN SUBWAY COMMISSIONERS.

In retiring from their now extinct offices as Subway Commissioners in Brooklyn, N. Y., Prof. G. W. Plympton and Mr. F. R. Lee have filed a farewell report with Mayor Wurster. It contains a number of interesting details. The figures as to wires in that city on October 1 are as follows:

	Miles.
Aggregate length of electric conductors of all kinds within city limits	21,957
Increase during this year	1,586
Total length of wires underground or suspended from elevated railways is	14,248
Increase since January 1	1,939
Total length of underground conduit is	136
Length of single duct	377

Sixty-five per cent. of all electrical conductors within city limits are under the streets or suspended from the trusses of the elevated roads, or, excluding the city's wire's from the estimate, 69 per cent. of all wires under the jurisdiction of this board are thus disposed of.

The subject of corrosion of underground pipes and cables still demands serious consideration. The survey made in 1894 of the electrical condition of the districts traversed by the trolley lines was not continued in 1895, for the reason that the Nassau trolley system was in process of construction, and the whole problem of underground currents was assuming larger proportions and presenting new complexities. As the new lines were practically completed early in the present year a new survey was made during the summer under the direction of Mr. John A. Barrett. This survey included numerous examinations of the water pipes which could only be made by excavations in the streets. In this work this board received the efficient and hearty co-operation of the department of city works. Excavations were made wherever it was deemed desirable to make a direct examination of the water main.

One gratifying conclusion was arrived at as a result of this thorough examination, and that was that in the districts where underground pipes are most liable to destruction by electrolysis the cast iron water mains remain intact. Wrought iron and lead pipes deteriorate steadily and rapidly, in places where cast iron shows no sign of decay. The statement in a former communication from this board that the water system of the city was seriously endangered and probably already impaired by electrolytic corrosion, now requires modification to the extent that such injury is confined to such branches as are constructed of wrought iron or lead. The immunity from injury by the ordinary process of oxidation, possessed by cast iron was long since pointed out by engineers, one of whom declared that it was his belief that the so-called white casting is practically indestructible under the action of ordinary oxydizing influences.

It would seem likely, therefore, in view of the perfect preservation of the water mains under conditions that lead to the destruction of wrought iron and lead pipes that, whether through design or not, the large pipes have been made of a quality of iron that insures their safety. The inconvenience and loss resulting from the electrolytic corrosion is not limited to the destruction of the pipe or cable covering. From the corrosion of gas pipes there results a leakage of gas which destroys trees, threatens the health of the neighborhood and increases the danger of explosions in manholes and cellars. The corrosion of water pipes leads to waste of the city's water supply, while the destruction of the buried electric cables tends to seriously limit the area within which electric conductors can be successfully operated in subways. Moreover, the destruction of either kind of so-called service pipe, whether delivering water or gas, calls for frequent disturbance of the street pavements. In some places service pipes extending beneath the trolley tracks have been repeatedly destroyed and removed, each removal of course requiring an excavation, refilling and a relaying of the pavement. It should be here stated, however, that destruction of the underground pipes is not limited to the streets occupied by the trolley lines. The trolley companies have during the year done much to keep the destructive current on the path of their own conductors so that the injury is doubtless less rapid than it was two years ago, but a means of absolute prevention of the injury so long as the pipes are of a kind liable to corrode, is not yet made known. The escape to the earth of a portion of the current discharged into the rail is a condition inseparable from the single trolley system. Non-metallic service pipes for conveyance, both of gas and water, are plainly desirable in the present emergency.

The total length of electrical conductors within the city limits when this board began its work in June, 1892, was in round numbers 9,800 miles, of which about 6,000 was on poles or house tops. Comparing these figures with the totals given above, it is shown that the increase in the length of wires during the existence of the board has been about 12,200 miles, of which amount somewhat over 10,200 miles have been provided for in conduits or on the elevated railways. One hundred and eighty miles of conduit containing 280 miles of single duct have been constructed in the same period.

NON-HYSTERETIC IRON FOR TRANSFORMER PLATES.

In dynamo electric apparatus there is in those parts of the iron core where the magnetic flux is varying—even where Foucault currents are suppressed by laminating it—a loss of energy due to hysteresis, which appears as heat in the iron and is called "core loss." It has been known for some years that this core loss in annealed iron cores, which become heated while the apparatus is in use, increases after such use has continued for some time, the increase being due to an increase in hysteresis. This increase in hysteresis accompanies long continued heating, such as that produced by the reversal of the lines of force in uncooled transformers as now ordinarily constructed. If the heating of the iron could be prevented, the increase of the hysteresis and resulting increase of core loss could also be prevented, but the cost of prevention of heating is such as to make it commercially impossible. Hence the increase of core loss has up to the present time been submitted to as a necessary evil. This evil is marked in alternating current dynamos and motors, but is probably greater in transformers than in other kinds of electrical apparatus. Its magnitude in transformers will be plain from the following figures: The average size of transformers at present is fifty lights, being such a transformer as would be used to light a large sized dwelling house of fifteen or twenty rooms. The average all-day load is quarter load, making its average output about seven hundred watts. The core loss in such a transformer, when new, will at a frequency of one hundred and thirty-three alternations per second be about 55 watts. After the transformer has been in use under ordinary conditions for some time there is, as above stated, an increase in the core loss due to hysteresis. This increased core loss in a comparatively short time amounts to at least 40 per cent., and later frequently rises to 100 per cent. of the original core loss. Taking it at only 45 per cent. it will in this case amount to about 25 watts, or over 3½ per cent. of the average output; that is to say, the average efficiency of the transformer will be reduced about 3½ per cent. To put it another way, the steady losses in a 10,000 light central plant installation would be increased by some 5 kilowatts, which, at the low rate of 1 cent per kilowatt hour, would cost the producer $1.20 a day, or $438 a year.

Heretofore, although the increased core loss has been recognized, all attempts to prevent it by changing the composition or character of the iron have been attempts to make a purer iron to exclude as far as possible all foreign substances. Mr. John F. Kelly, of the Stanley Electric Mfg. Co. of Pittsfield, Mass., however, has discovered that the hysteresis growth which gives rise to the increase of the core loss can be prevented by intentionally having the iron of the core contain one foreign substance such as silicon in suitable proportions. One proportion suitable for attaining the object is 0.0235 per cent. of silicon, the other parts being pure commercial iron.

The amount of silicon in the iron used by Mr. Kelly, it will be noticed, is considerably larger than that present in the ordinary iron used for laminated cores. The abnormal amount of silicon in the iron does not increase the original core losses in perfectly annealed iron, but prevents the hysteresis growth at the temperatures to which the transformers are subjected when in use. The iron with the hysteresis growth-preventing silicon alloy is more springy than iron ordinarily used in cores, in addition to being more difficult to anneal. The alloy appears to resist molecular change of any sort.

THE TESTING OF HEAVY INSULATORS.

BY NEVIL MONROE HOPKINS.

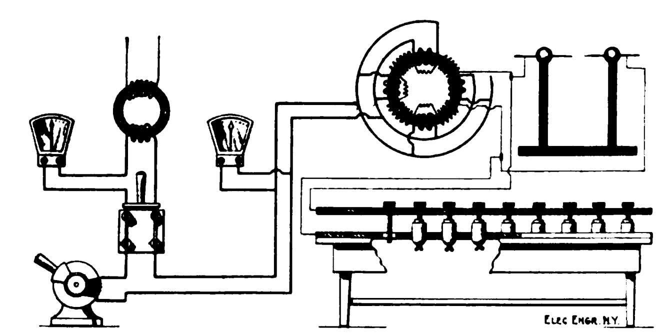
The testing of heavy insulators designed for high tension service is of great importance before their shipment and installation. Delicate measurements of resistance would mean very little as no reliable information concerning the future behavior of the insulator when put in actual use would be gained, for leaks would develop and defects come to the surface when put under the strain of the high tensions employed in certain classes of railway work and long distance power transmission. The actual "break down" test is based on the theory that an insulator which is able to resist puncture when submitted to a tension of 30,000 volts for a period of thirty or forty minutes is capable of effectually insulating a current with a potential difference of 1,000 or 2,000 volts for an indefinite period. Is it altogether wise to submit a porcelain insulator to such an abnormal stress?

It would undoubtedly be preferable not to do so if gentler means were at hand to learn of its collapsing point. In the case of the hydraulic testing of steam boilers which are never benefited by an abnormal test pressure, the same argument may be applied. In either case heroic methods appear to be the only practical courses, and perhaps after rejecting those insulators which become at all heated during the test a reliable knowledge of their insulating qualities can be reached.

The accompanying diagram shows the arrangement of apparatus best adapted to this special test. Alternating current is received at the first transformer at 1,000 volts and it is stepped down to 100 volts before the indicating instruments are connected in and the primary of the high transformer fed. Should this step down be omitted, any accident to the high potential transformer, such as a short circuit between its primary and secondary, would put the alternator in danger.

A "choking" or controlling coil is included in the circuit with the ammeter, and after crossing the terminals of a voltmeter the conductors are led directly to the high potential transformer, as shown in the diagram. Here the voltage is stepped up from 100 volts to 30,000 volts by means of the single, wire ring transformer. The table on which the insulators are placed is provided with a copper, or sheet iron top with holes punched through to receive the insulators. Wooden strips with copper covered tops carry the metal bolts that drop through and rest on the bottom of the insulator. A hard rubber or wooden stand carries copper needles which may be easily adjusted.

In the present case, the needles are separated one and one-half inches and a discharge will take place across the air gap should the voltage rise above 30,000. A loud humming noise begins on closing the circuit, accompanied by a strong odor of ozone until an insulator breaks down under the stress and



Method of Testing Large Porcelain Insulators.

begins to sing at a low pitch until it cracks and heats up to a red heat in the neighborhood of the puncture. Any defects in the moulding of the clay, or any conducting mineral that may be present, immediately starts a slow leak that frequently ends in puncture.

A loss of from 8 to 10 per cent. is usual in carefully made insulators, when subjected to 30,000 volts. Insulators that contain some conducting mineral in the clay frequently begin to leak within five or ten minutes and a regular conducting passage seems to form which raises the temperature of the whole insulator without doing any apparent damage. Specimens which behave in this manner are frequently overlooked in the test, for they do not puncture and sing, and it hardly need be mentioned that they should not be passed as perfect. Those that remain cold during the thirty minutes are as near perfect as can be detected.

OBITUARY.

ELBREN S. BOWERS.

The body of Mr. E. S. Bowers, who disappeared suddenly from his home at Evanston, Ill., on the evening of Sunday, October 25, was discovered floating in Lake Michigan at the foot of Main street, South Evanston, on November 2. Mr. Bowers, who carried on the business of Bowers Bros., dealers in mica, at 119 Lake street, Chicago, for the past eight years, was the surviving member of the firm. He attended the American Street Railway Convention at St. Louis the week before his disappearance, where the firm had an exhibit in conjunction with the Central Union Brass Company, of St. Louis, and appeared to be in his usual health and good spirits. On his return to Chicago he complained to his mother, Mrs. Mary Bowers, with whom he resided, of not feeling well, and was worse on Sunday and left the house while Mrs. Bowers went to dress to go out for a walk with him. From there he went to a drug store in Evanston, and it is believed that he then walked down to the end of the new breakwater and threw himself into the lake. Mr. Bowers had suffered from an affection of the mind some years ago after an attack of grippe, and had been in an asylum for a short period, and it is surmised that he had a return of the old symptoms, which led to his committing the sad act.

He was 35 years old, unmarried and carried on his business in a very successful manner. He was a man of most genial disposition and of the highest integrity, and his untimely death will be greatly regretted by his numerous friends. His remains were removed for interment to Ackwood, N. H., on November 4.

W. L. CORTHELL, the superintendent of the Derry, N. H., Electric Light Company, has died of typhoid malarial fever.

SOCIETY AND CLUB NOTES.

LAYING THE CORNERSTONE OF THE COLUMBIA ENGINEERING BUILDING.

The cornerstone of the Engineering Building, at the new site of Columbia University was laid on Wednesday, November 4. Addresses were made by President Low and Henry S. Monroe, E. M., Ph. D., professor of mining, and the benediction was pronounced by Bishop Littlejohn, of Long Island. The cornerstone was laid by Francis B. Crocker, Ph. D., professor of electrical engineering. At the same time was laid the cornerstone of Havemeyer Hall, the building generously given to the chemical department of the university by the Havemeyer family. These, together with the Low Library, Physics Building, Schermerhorn Hall (Natural Science) and the University Hall, will be completed in time for occupancy next October, when the university will open its new home. Other buildings will be added later, as demands for space increase. The admirable design and arrangement of this collection of buildings will secure a maximum of convenience and effectiveness, which is not possible when the separate buildings are erected by different architects at long intervals of time. Some idea of the scale of the new Columbia may be gathered from the fact that the electrical generating plant will have 750 horse-power capacity to start with, and will be increased later.

THE ELECTRICAL SOUND MONEY CLUB AND ITS PARADE.

We print below the general order No. 2, just issued by Gen. C. H. Barney, as marshal of the electrical brigade in the sound money parade, described fully in The Electrical Engineer last week:

"Electrical Sound Money Club—Headquarters Electrical Brigade.

"New York, November 2, 1896.

"General Order No. 2.—The marshal of the electrical brigade in the business men's parade of the 31st ultimo hereby returns thanks to all those who took part in that splendid demonstration as members of this command.

"He desires first to acknowledge his great obligations to the officers of the Electrical Sound Money Club for their cheerful and hearty co-operation and support in the work of preparation, and for the inspiration afforded by their presence at the head of the column during the parade.

"In thanking the various organizations of the brigade whose fine appearance and good marching were the subject of so much favorable comment, he feels that as all deserve praise, it would be invidious to compliment any particular organization; officers and men all did well. He deems it proper, however, without derogation to the services of the other regimental commanders, to call attention to the fact that Col. Frank M. Anderson, commanding the second regiment in the brigade, is deserving of great credit for the ability which he displayed in organizing and instructing his command, with less than forty-eight hours for that purpose, so that in appearance and marching it was not surpassed by any battalion in the brigade.

"The marshal heartily thanks the members of his staff for their great assistance in the work of preparing and handling the parade, and desires especially to acknowledge the valuable services of George F. Porter, chief of staff; Edward P. Decker, brigade engineer, and Aides F. S. Blackall, Paul A. Ferry and E. T. Rice. C. H. BARNEY, Marshal."

THE ELECTRICAL SOUND MONEY CLUB.

Before the great parade for "sound money" in New York City on October 31 passes into history it is only proper to accord due credit to the Electrical Sound Money Club, which organized the electrical brigade, as described by us last week. The success must be very largely ascribed to the efforts of Mr. Charles Blizard and Mr. S. L. Coles, both of whom worked very hard, and gave a great deal of time and thought to the matter. The officers of the club were Gen. E. S. Greeley, president; U. N. Bethell, A. S. Brown, F. W. Jones, F. A. Pickernell, S. S. Wheeler, Charles Blizard, A. L. Salt, vice-presidents; S. L. Coles, secretary; W. L. Candee, treasurer. The subscriptions from the trade and profession were liberal, and the whole thing reflects the greatest credit upon those engaged in it.

THE AMERICAN INSTITUTE OF ARCHITECTS, at its thirtieth annual convention at Nashville, Tenn., voted to continue to be represented in the conference having in charge the establishment of standard electric rules.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Alternating Current:

INFLUENCE OF INSTALLATION RESISTANCE AND CAPACITY IN ALTERNATING CURRENT INSTALLATIONS ON POTENTIAL AGAINST THE GROUND.—By A. V. Ettinghausen and G. Ossanna. Authors explain methods for testing insulation by means of electrostatic voltmeters and show diagramatically various effects on various lines. "Zeitschr. f. Elektrotechn." Sept. 15, '96.

WORKING ALTERNATORS IN PARALLEL AT HASTINGS.—Mr. L. Andrews has devised a simple method for running the alternator in his station at Hastings in parallel. The sketch of the arrangement on the switchboard is necessary for a clear understanding and is to be found in the "Engineer," Oct. 9, '96.

Central Stations:

THE CENTRAL STATION AT ZURICH.—By Ch. Jacquin. A detailed illustrated description in "L'Eclairage Electrique." Sept. 12, '96.

Dynamos and Motors:

SPARKING IN ARMATURES.—By J. Fischer-Hinnen. Determination of formulæ for calculating the distance of the brushes from the neutral point. Different types of armature windings are considered. "Electrotechn. Zeitschr., Sept. 17, '96.

Electro-Chemistry:

ELECTROLYTIC PREPARATION OF A NEW CLASS OF OXYDIZABLE MATERIALS.—By E. J. Constam and A. von Hansen. An exhaustive study with potassium carbonates.

Electro-Physics:

ELECTRIC POTENTIAL IN MOVING LIQUID.—By G. Gouré de Villemontée. Author reviews the history of this investigation, which was started as early as 1871, and gives account of his own work. It has usually been observed that a difference of potential exists between two points in a liquid. "L'Eclairage Elec." Sept. 12, '96.

Measurements:

MIRROR GALVANOMETERS.—By Dr. Hilmar Sack. A Deprez d'Arsonval galvanometer investigated by Dr. Classen and published in detail on page 676 of the "Electrotechn. Zeitsch.," 1895, is shown by the author to cause inaccuracies in several details. An improved form manufactured under the author's supervision by Siemens & Halske, is described in "Elektrotechn. Zeitschr.," Sept. 17, '96.

ELIMINATING MAGNETIC DISTURBANCES IN THE SENSITIVE GALVANOMETER.—By Dr. A. Raps and Dr. A. Franke. Besides the arranging of iron wire bundles outside of the instrument, two small supplementary very weak magnets were attached to the movable system and used to make the needles perfectly astatic. "Elektrotechn. Zeitschr." Sept. 17, '96.

ELECTROSCOPE WITH THREE GOLDLEAVES."—By L. Benoist. Three goldleaves are suspended side by side at the lower end of the isolated metal rod; when these become charged the middle one will keep its vertical position, while the two others will diverge outward. The sensitiveness is increased with small angles in a ratio of about 3 to 2, and still more favorable in large deflections. "Compt. Rend.," page 171, '96.

BALANCE FOR ABSOLUTE MAGNETIC MEASUREMENTS.—By Dr. Karl Strecker. Description accompanied by drawings to illustrate to the student the methods of determining magnetic movements and the absolute number of lines of force. "Zeitschr. f. d. Phys. & Chem. Unterr.," Sept. '96.

SIMPLE MODEL OF AN INFLUENCE MACHINE.—By K. W. Dubrowsky. Description of a simple piece of apparatus which for a small outlay can be made of sufficient strength to light up a Geissler tube or charge a Leyden jar. "Zeitschr. f. d. Phys. & Chem. Unterr.," Sept. '96.

Railways:

TRAMWAY STATISTICS IN FRANCE.—Details of several roads are tabulated in "L'Eclair. Elec.," Sept. 26, '96.

ACCUMULATIONS ON STREET RAILWAYS.—The storage battery, which has been running in Hanover for one year is said to be a success in the "Zeitsch. f. Elektrotechn.," Oct. 1, '96.

Telephony, Telegraphy, etc:

ELECTRIC SIGNALS OF THE VIENNA FIRE ALARM SERVICE.—By Willy Chitil. A description of the entire system where, among other devices, methods for calling the volunteers are employed. "Zeitschr. f. Elektrotechn.," Oct. 1, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED NOV. 3, 1896.

Alarms and Signals:—

ELECTRIC ALARM BELL. R. Segerdahl, Chicago, Ill., 570,508. Filed June 27, 1892.
Details of construction.

BURGLAR ALARM. F. Steinkoenig, Sioux City, Iowa., 570,616. Filed June 12, 1896.
Means for giving notice in all of the apartments excepting that into which the burglar has broken.

TRACK INSTRUMENT. T. B. Dixon, Henderson, Ky., 570,700. Filed Sept. 12, 1895.
For transmitting signals.

Batteries, Secondary:—

PROCESS OF MANUFACTURING PLATES FOR SECONDARY BATTERIES. C. H. Weise, Possneck, Germany, 570,619. Filed April 4, 1895.
Consists in confining a pasty mass of lead compound in an acid proof frame having perforated sides, passing cellulose threads through the perforations of the frame, placing the same in an acid bath, passing an electric current through the same, and finally exposing the formed hardened plate to the action of the air to destroy the chemically changed cellulose.

Electro-Metallurgy:

ELECTRODEPOSITION. E. Jordis, Munich, Germany, 570,554. Filed June 29, 1896.
Consists in preparing a bath containing the lactate of the metal to be deposited, and then precipitating the metal by means of an electric current.

Lamps and Appurtenances:—

INCANDESCENT LAMP SOCKET. A. Swan, New York, 570,517. Filed Jan. 23, 1896.
Embodies a removable base.

ELECTRIC ARC LAMP. H. A. Seymour, Washington, D. C., 570,823. Filed July 1, 1896.
Alternating current lamp of the enclosed arc type.

ELECTRIC ARC LAMP. H. A. Seymour, Washington, D. C., 570,824. Filed July 7, 1896.
Similar to above.

CARBON FOR ARC LAMPS. D. A. Sheeler, Toledo, Ohio, 570,825. Filed Feb. 18, 1896.
Consists of graphitoid silicon asbestos, carbon, and a binder.

GLOBE FOR ELECTRIC ARC LAMP. M. B. Bailey, Chicago, Ill., 570,446. Filed July 11, 1894.
One part of the globe is opaque and provided with series of reflecting corrugations.

BRACKET FOR PENDENT ELECTRIC LIGHT GLOBES. J. Christiansen and R. W. Pittman, Hartford, Conn., 570,452. Filed Jan. 5, 1895.
Comprises a suspension member; a weight secured thereto for adjustment directly below or laterally of the suspension member, and means carried by the weight and adapted to support a lamp.

STREET LAMP HANGER. H. P. Hill, Washington, D. C., 570,801. Filed Dec. 6, 1895.
Comprises a lamp rope provided with an enlargement, a bifurcated pawl, embracing the rope, and inclined tracks adapted to direct the enlargement upon the lamp rope away from the pawl.

Miscellaneous:

GALVANOMETER. C. Coleman, Chicago, Ill., 570,454. Filed June 9, 1896.
Comprises a pivoted armature and a magnet having pole-pieces provided with overlapping portions whose opposing surfaces are parallel and concentric with the axis of motion of the armature.

INSTRUMENT FOR MEASURING ELECTRIC CURRENTS. R. M. Hunter, Philadelphia, Pa., 570,481. Filed Oct. 4, 1892.
Employs a wire under tension through which a small current is caused to flow, and in its expansion and contraction acts upon a pivoted needle traversing a scale.

Miscellaneous:—

MAGNETIC SEPARATOR FOR THRESHING MACHINES. E. H. Osborne, Des Moines, Iowa, 570,496. Filed Jan. 24, 1896.
Magnets are employed to arrest a metallic body in passing through the machine and means are provided for sounding an alarm.

ELECTRICALLY CONTROLLED ELEVATOR. S. D. Strohm, Philadelphia, Pa., 570,827. Filed April 4, 1896.
Means to prevent the operation of elevator when any of the landing doors are open.

TOWINGAPPARATUS . A. De Bovet, Paris, France, 570,839. Filed April 5, 1894.
Means to convert carrying barges into tow boats capable of being towed individually along a chain sunk beneath the water. The chain passes over a magnetized pulley.

ELECTROMAGNETIC WARP STOP-MOTION FOR LOOMS. A. C. Shuttleworth, Philadelphia, Pa., 570,738. Filed April 30, 1894.
Details of construction.

Railways and Appliances:—

TROLLEY. J. A. Hance, St. Louis, Mo., 570,475. Filed Feb. 26, 1896.
Comprises two grooved wheels mounted in a frame, two smaller grooved wheels also mounted in the frame in a running line with the others, the frame being pivotally mounted on the trolley pole.

ELECTRIC RAILWAY. H. C. Reagan, Jr., Philadelphia, Pa., 570-565. Filed March 11, 1896.
A conduit system in which magnets are employed to actuate the contacts carried by the car.

MAGNETIC PATH FOR UNDERGROUND ELECTRIC RAILWAYS. H. C. Reagan, Jr., Philadelphia, Pa., 570,566. Filed April 21, 1896.
Comprises a conduit, a casing, a series of independent magnetic paths, supported above the conduit, and a magnet having soft iron shoes attached to each pole, the shoes extending over one or more magnetic paths.

RETURN CIRCUIT FOR ELECTRIC RAILWAYS. G. Kapp, Berlin, Germany, 570,599. Filed Dec. 31, 1895.
Insulated return feeders connected to the track at points remote from the power station, and auxiliary sources of electromotive force inserted in the return feeders to decrease the difference of potential.

Regulation:—

METHOD OF AND APPARATUS FOR REGULATING DYNAMO ELECTRIC GENERATORS AND MOTORS. J. W. Easton, Brooklyn, N. Y., 570,663. Filed April 1, 1892.
A circuit controlling device actuated by vibrations in the output of the machine for varying polarity of one set of pole pieces independently of the others.

MULTIPLE SERIES CONTROLLER. J. F. McElroy, Albany, N. Y., 570,878. Filed Aug. 28, 1894.
A frame having a positive and negative pole, a means for conducting the electricity in multiple series, a means for breaking the circuit forcibly and abruptly and simultaneously unlocking the controller.

Switches, Cut-Outs, Etc:—

SAFETY SWITCH. E. Jokl and W. M. Christian, Vienna, Austria-Hungary, 570,808. Filed Aug. 14, 1896.
Apparatus for throwing automatically into circuit reserve lamps or motors in place of such apparatus which have been damaged so that the current cannot pass through them.

AUTOMATIC SAFETY DEVICE FOR ELECTRIC CIRCUITS. L. G. Rowand, Camden, N. J., 570,882. Filed Sept. 13, 1895.
Particularly adapted for trolley lines in streets.

Telegraphs:—

TYPE PRINTING TELEGRAPHIC APPARATUS. F. H. W. Higgins, London, England, 570,852. Filed Oct. 11, 1895.
Details of construction.

Telephones:—

TELEPHONE SWITCH. C. N. Sandbeck, Harmony, Minn., 570,773. Filed April 8, 1896.
For use in connecting two telephones of a series.

AUTOMATIC TELEPHONE SYSTEM. M. Brooks, Minneapolis, Minn., 570,840. Filed Jan. 26, 1895.
Means whereby subscribers may call and talk with one another without the interposition of a central switchboard.

SUBSTANCE FOR TELEPHONE ELECTRODES. D. Drawbaugh, Eberly's Mill, Pa., 570,845. Filed Jan. 10, 1896.
Composed of a substance having its surface covered with platinum black.

REPORTS OF COMPANIES.

DRAWBAUGH TELEPHONE CO.

At the annual meeting of the stockholders of the Drawbaugh Telephone and Telegraph Company, held at the office of the company, No. 2 Wall street, New York City, President Bartlett spoke at length regarding the bill now pending before Congress, removing the technical bar of two years' public use, which was imposed upon Drawbaugh by the ruling of the Commissioner of Patents. The address was delivered in view of the fact that some public misapprehensions might exist, owing to recent dispatches from Washington regarding the action of the Court of Appeals, which a few days ago affirmed the decree of the Commissioner of Patents "turning down" Drawbaugh. The following were elected directors: John R. Bartlett and H. C. Andrews, of New York; Hon. Frank Jones, New Hampshire; Parker C. Chandler, Boston; Col. J. F. Stokes, Philadelphia; Hon. James Jourdan and Abel E. Blackmar, Brooklyn. The officers of the company expressed confidence from assurances they have received, that the ultimate outcome of the government suits will be favorable to the Drawbaugh Company, and that the bill now pending in Congress will be passed.

WINDING UP THE ELECTRICAL EXPOSITION.

The National Electrical Exposition Company, through its directors, George F. Porter, Edward F. Peck, and others, has applied to the Supreme Court for the voluntary dissolution of the company, and Judge MacLean has set down the order to show cause for Feb. 1, 1897. The company was incorporated on Nov. 25, 1895, with a capital stock of $10,000, of which $2,000 was paid in, for the purpose of keeping for a short period an electrical exposition or display. The object has been accomplished, and there is no longer any necessity for continuing its corporate life. The enterprise was financially successful, the company is entirely solvent, has a surplus in the treasury, and no creditors. The assets consist of cash $764, and accounts receivable $577.

LEGAL NOTES.

A DECISION ON TROLLEY SPEED IN BROOKLYN.

Civil Justice Neu, of Brooklyn, recently imposed a fine of $25 on the Nassau Electric Railroad Company for an alleged violation of the trolley speed ordinance. The company took an appeal to the County Court, and now Judge Hurd has handed down a decision reversing that of Justice Neu.

He holds that the city must prove wilful and negligent violation of the ordinance and that stopwatch timing of a run of 300 feet is not sufficient. More than sixty similar suits against the trolley companies are pending. The city will probably appeal from Judge Hurd's decision.

SUIT AS TO TELEPHONIC SWITCH PATENTS.

A bill in equity has been filed by the Western Telephone Construction Company, of Chicago, against the Philadelphia Standard Telephone Company, Joseph H. Mann, president; Richard W. Clay, treasurer, and W. Frederick Snyder, general manager, and the Union Traction Company, and Allen T. Nye, all of Philadelphia, and the Standard Telephone Company, of New York, alleging infringement of patent.

It is alleged that Henry M. Fisk was the original inventor of an improvement in combined annunciator and spring jack, for which he obtained a patent, and which he subsequently assigned to the plaintiff, giving the latter exclusive use thereof. The defendants are, it is alleged, using and selling telephone switchboards, infringing on the patented inventions named. The Court is asked to enjoin them from doing so.

THE BELL TELEPHONE ARGUMENT began on Monday in the United States Supreme Court.

PERSONAL.

MR. GEORGE HELI GUY, the secretary of the New York Electrical Society, has returned from a two months' trip to England, and is busily engaged laying out an attractive winter programme for that popular and successful organization.

NEWS AND NOTES.

JAMAICA, N. Y.—The Jamaica Electric Light Company advises us that it is building a new plant. Its present system is Ball arc and Stanley incandescent. The officers are W. S. Williamson, president; W. T. Goundie, vice-president; O. L. Schwencke, secretary and treasurer; J. N. Williamson, superintendent and manager.

MORAVIA, N. Y.—The Moravia Electric Light, Heat and Power Company, owing to low water power, has, it informs us, bought a 125 horse-power engine. The officers are W. J. H. Parker, secretary, and W. Fitts, treasurer.

OWOSSO, MICH.—The Caledonia Electric Light and Power Company has absorbed the Owosso Electric Light Company, and has had plans drawn, it informs us, for a two-story brick addition to its station. The apparatus is General Electric, Triumph and Westinghouse. John L. Ralph is president, I. D. H. Ralph treasurer and general manager. The company is running three cars for the Owosso and Corunna Traction Company.

WINONA, MINN.—The Winona Railway and Light Company informs us that it has now elected as its officers C. A. Severance, president; M. B. Webber, secretary; F. A. Seymour, treasurer; S. B. Livermore, general manager. The company has a Thomson-Houston railway system, and Thomson-Houston, Edison and Westinghouse lighting, twelve dynamos in all. The converters are Wagner and Elkhart. About 100 horse-power c. f. motors are run and five cars. The power plant comprises five engines, one Buckeye, two Ball & Wood, one Ball and one Ideal.

LITTLESTOWN, PA.—The Leber Electric Company, L. H. Leber, manager, is in the market for the equipment of two plants, one 30 kilowatt alternating and one 250 arc. The company has a large amount of lighting contracted for.

NEWPORT, N. H.—The Newport Electric Light Company is reported by M. W. Tenney, superintendent, to have a contract with the town for five years for twenty arc lights and twenty-two incandescents for street lighting. The plant is run by turbines of 175 horse-power. There are one 45 arc lighter, 1,200 c. p.; one 35-light and one 60-light alternating, and twenty miles of circuit. S. M. Richards is president and W. F. Richards treasurer.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE AMERICAN ELECTRIC METER.

UNDER this name the American Electric Meter Company, Betz Building, Philadelphia, Pa., of which Prof. W. D. Marks is president, have just brought out a type of mechanical meter which, it is claimed, overcomes the difficulties which have been experienced in the past with this class of apparatus and which, besides being economical in current consumption, requires no electrical knowledge for its erection and operation.

The accompanying engravings show, respectively, the meter closed and with the case open, exposing the mechanism. The meter consists in the 3-wire system of two solenoids and cores placed above a self-starting pendulum actuated by the electric current. The pendulum, by means of a cam, raises a pawl on a ratchet wheel to a uniform height each stroke. The solenoids, by means of their cores, shift the angular position of a pendant arch attached to their axis so as to permit this pawl to drop along the ratchet wheel a number of teeth proportional to the current passing through the meter; thus at each stroke of the pendulum the load in amperes passing to the consumer is by means of the ratchet wheel and the dial register, measured and added up in ampere hours. A pointer and scale show through the glass the amperes passing. The interior mechanism is supported by a brass frame, similar to that of a Yankee clock, and the case is cast iron, thus acting as a magnetic shield and preventing tampering with the meter by means of magnets on the outside.

FIG. 1.—THE AMERICAN ELECTRIC METER.

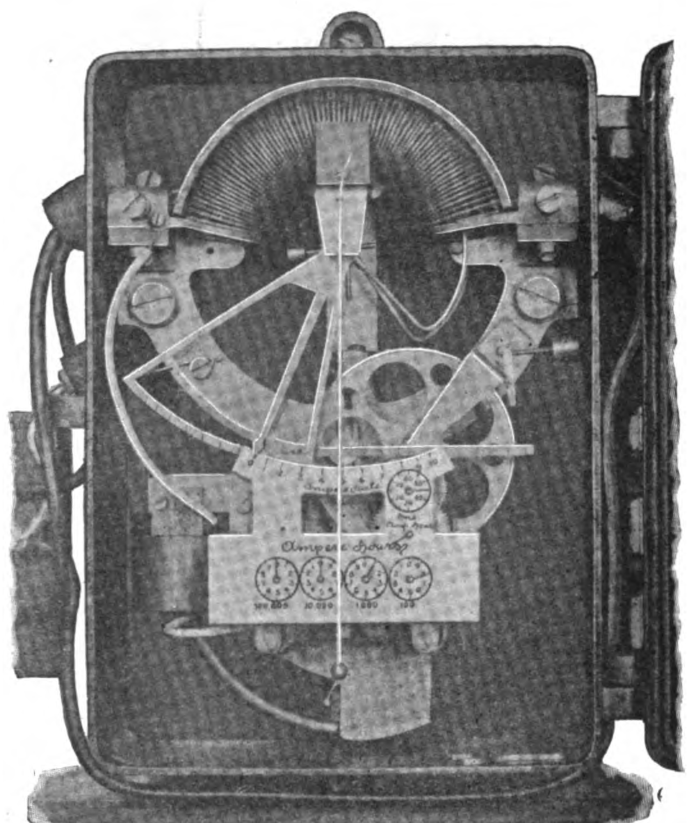


FIG. 2.—THE AMERICAN ELECTRIC METER.

As to the accuracy of the meter, a series of observations taken at random from a large number of experiments, covering more than a year's work, showed the variations in the solenoids of the manufacturer's model to involve no greater average error than 0.05 ampere in excess, in a 22 light three-wire 10 ampere meter. The error in the solenoids is corrected by allowances in the curvature of the pendant arch controlling the number of teeth picked up by the pawl on the ratchet wheel.

The meter requires to operate its pendulum about four-tenths (4-10) of a watt for a twenty-two light meter; 1,865 of these meters can be operated by one horse-power. Large sizes can be operated for a trifle more power. There is no increase of power required in proportion to the size of the meter because there is no brake and no increase of speed with larger loads.

In erecting the meter the only adjustment necessary is to see that the plumb bob hangs vertically. The meter is sent out calibrated. As all heavy bearings are roller bearings, there is no need of lubrication anywhere about the meter, so that an annual inspection is all that is necessary.

The American meter is the outcome of several years' continuous experimenting, and is built under the patents issued January 29, 1895, and March 10, 1896: and under patents allowed as follows: Serial No. 582,295, May 13, 1896; Serial No. 582,296, May 19, 1896; Serial No. 582,292, May 25, 1896, and Serial No. 582,293, July 2, 1896. Other patents have also been applied for.

SHIPMENT OF AMERICAN BALL ENGINES.

The American Engine Company, of Bound Brook, N. J., have begun the shipment of their new engine known to the trade as American-Ball Engines. The first of these engines of 100 horse-power capacity has gone to the Detroit "Evening News," and the second, a 50 horse-power engine, to the Savannah "News." Since the addition of this new line of work, the business of the American Engine Company has increased so that they are now compelled to run double time, having installed a night force. In the electrical department, among the recent shipments are the following: Cliff Paper Company, Niagara Falls, N. Y., 2 motors, 150 horse-power each; Detroit "Evening News," Detroit, Mich., 2 dyamos, each 25 kilowatt; "Albany Morning Express," Albany, N. Y., one 18 kilowatt dynamo; "Oakland Tribune," Oakland, Cal., 25 horse-power motor; A. N. Kellogg Newspaper Compnay, Chicago, Ill., four 15 horse-power and one 25 horse-power motors; "Topeka Capital," Topeka, Kas., 5 horse-power motor; "Boston Traveller," 12 horse-power and 5 horse-power motors; "Worcester Post," Worcester, Mass., 9 kilowatt dynamo; "Cincinnati Post," Cincinnati, O., 35 horse-power motor; "Philadelphia News," 25 horse-power and one 3 horse-power motors; "Elmira Gazette," 25 horse-power motor; American Newspaper Publishing Company, 25 horse-power motor; Carrington Publishing Company, 12 horse-power motor; J. B. Cranfill, Waco, Tex., 25 horse-power motor; Fall River Publishing Company, Fall River, Mass., one 25 horse-power and 3 horse-power motors; "Saginaw Evening News," Saginaw, Mich., 12 horse-power motor; B. A. Meade Company, Augusta, Me., 3 horse-power motor; "Chicago Journal," 15 horse-power motor; "Grand Rapids Democrat," 15 horse-power and 3 horse-power motors; "St. Paul Pioneer Press," St. Paul, Minn., 5

horse-power motor; Wallace Publishing Company, Des Moines, Ia., 12 horse-power motor; "New York Tribune," two 15 horse-power motors; Rubber Tire Wheel Company, New York, N. Y., 12 horse-power motor.

THE L. E. KNOTT X-RAY APPARATUS.

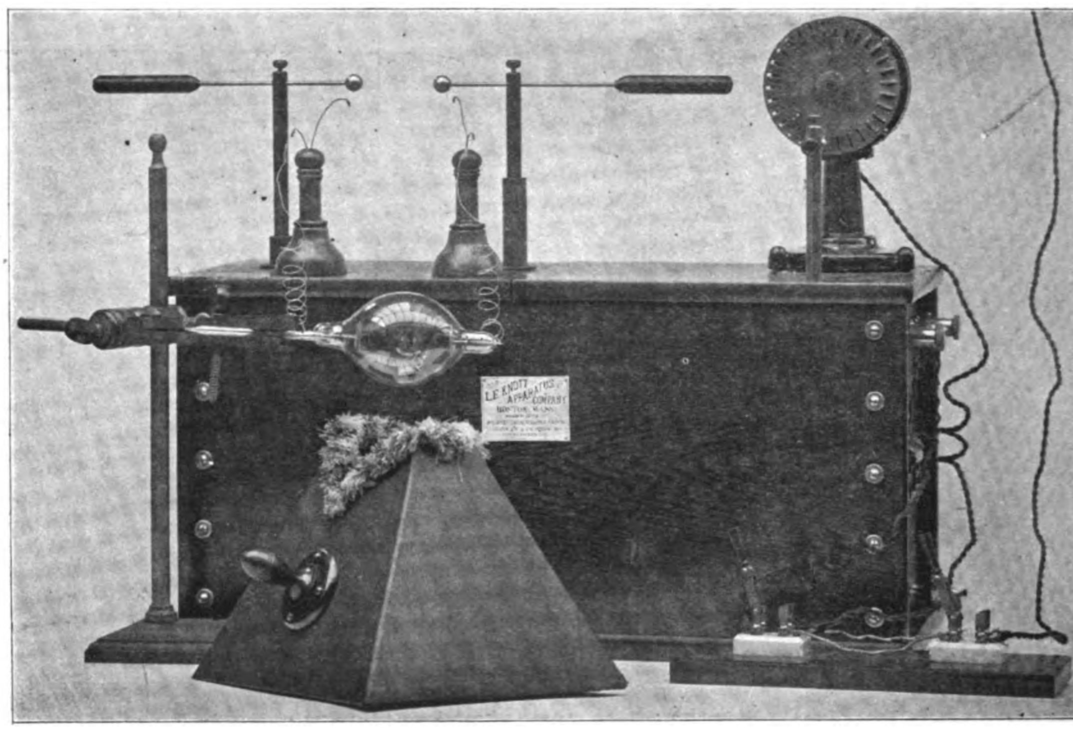
THE accompanying engraving represents the complete set of X-ray apparatus now being introduced by the L. E. Knott Apparatus Co., of Boston. The entire set of apparatus occupies no more space than the coil with condenser, and not so much as the static machine.

The arrangement represents the apparatus as now extensively used in many of the leading hospitals where an alternating current is available. In this apparatus the required voltage is obtained by a powerful step-up transformer, the secondary of which is used to charge a condenser, which in turn is discharged through the primary of the Tesla coil. The secondary of the Tesla terminates in the discharge poles shown in the cut, the transformer, condenser and Tesla coil all being contained in the case.

So far the instrument differs only in compactness from other high frequency coils which have been made. The uniform discharge of the condenser, however, is a point which heretofore has not been successfully obtained. The combined spark gap and air blast attached to the motor shaft renders this absolute and sure. To run this machine successfully requires only 4½ amperes at 52 volts, or 2¼ amperes at 104 volts.

By an easy adjustment of the binding posts on the outside of the case either 52 or 104 volts may be used without any external resistance. The operation of the apparatus is controlled by the two switches shown in the engraving. While the success of this instrument is unquestioned by those who have seen it in operation, many have been debarred from using it through not having an alternating current accessible. This difficulty, however, has recently been overcome by the devising of a successful interrupter with this latter device, which is mounted on the same motor which bears the spark gap discharger. The continuous current primary is interrupted 12,000 times per minute.

By an easy adjustment of the binding posts on the outside of stream of discharges is produced between the terminals; in this case, however, only in one direction. In the use of this instrument a single reflector tube is employed, the same as has been used in the induction coil or static machine.



THE L. E. KNOTT X-RAY APPARATUS, WITH TESLA COIL.

THE ALEXANDER-CHAMBERLAIN COMPANY have removed their offices to 56 West Twenty-second street, New York.

F. E. BAILEY & CO.

Messrs. F. E. Bailey & Company, of Philadelphia, have secured the contract with the Birdsboro Electric Light and Power Company, for the building of a complete electric light plant having a capacity of 1,000 lights.

The same firm, as representatives of the Armington & Sims Engine Company, have recently received orders for the following engines: One 150 horse-power engine, connected to line shaft, for the electric light plant owned by the borough of Quakertown, Pa.; one 500 horse-power engine to be directly connected to line shaft for the Nanticoke Electric Light, Heat and Power Company, Nanticoke, Pa. One 130 horse-power engine, direct connected to line shaft for the Birdsboro Light and Power Company, Birdsboro, Pa.; two 40 horse-power engines and one 140 horse-power engine for the Mansion House Electric Light Plant, Reading, Pa.

Most of these engines are of the new self-oiling type, with the improved governor, which are in great demand at the present time.

The Armington & Sims Works are running day and night of late in order to be able to deliver on time the large number of engines that they have orders for.

THE MICHIGAN MINING SCHOOL.

The Michigan Mining School has recently issued a catalogue which for thoroughness in point of detail will be found difficult to rival. It has been the aim of the compiler to answer every question put to the director regarding the school since its establishment in 1887. The book contains 285 pages descriptive of the different courses with cuts illustrative of the buildings. It also embodies much valuable data on the mineral resources of the State with maps showing the location of the various mines.

This School, situated as it is in the heart of the mining district, is one of the best equipped colleges of the middle West and offers the student every opportunity for practical experiment and observation.

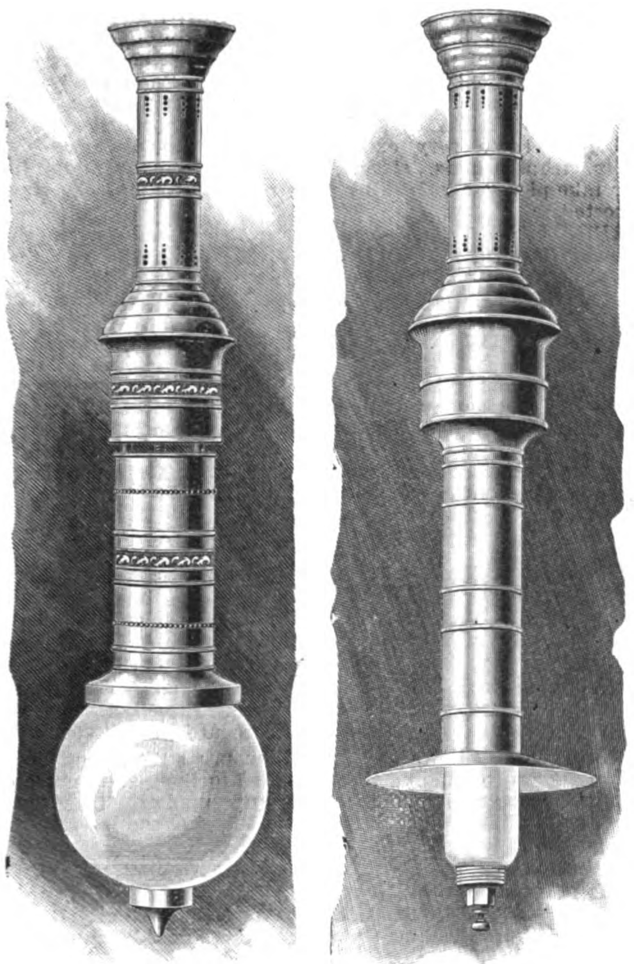
The electrical course was one of the first instituted, and the instruction is such as to afford an exact knowledge of the subject in its many applications to lighting and power work. The special object is to fit the student to be an engineer in the fullest sense of the term, rather than to have him devote all his time on applications whose details are constantly changing and which will not ultimately prove of advantage to him.

THE DIEHL CO.'S ENCLOSED ARC LAMP.

THE latest product of the works of the Diehl Manufacturing Company, of Elizabethport, N. J., is an enclosed arc lamp, the design of the company's well-known lamp expert, Mr. John Knight.

Besides the now well recognized features of the enclosed arc, the Knight lamp claims special attention on account of the method of clamping the globe, which does away with the cumbersome side castings or rods, and thereby eliminating the usual shadow. The construction is such that any ordinary straight lamp chimney, such as is commonly used with an argand burner, may be substituted in case of breaking, thus relieving the user of the necessity of keeping a supply of specially made globes.

The pair of solenoids are securely fastened top and bottom, which gives the mechanical construction strength and simplicity, and the clutch consists of a tilting washer. Our illustration, Fig. 1, shows the new lamp complete, while Fig. 2 shows the lamp with inner globe and reflector. This is adapted for lighting storehouses and large areas, and takes only three amperes.



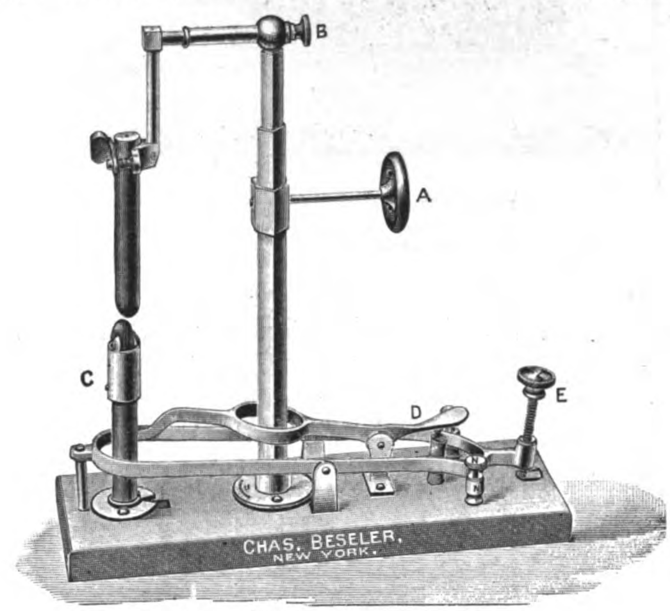
THE DIEHL CO.'S ENCLOSED ARC LAMP.

The Diehl Company also manufactures a regular series arc lamp. These lamps have an auxiliary striking magnet which prevents the chattering of the carbons and insures the striking of the full arc immediately the lamp is switched in circuit. These lamps are built for circuits of from 4 to 10 amperes, with a pressure of 45 volts, and can be connected two in series across 115 volt and 4 in series across 230-volt circuits. These lamps are built in a variety of styles for interior and street use.

The Diehl Company have added extensive machinery to their already large equipment for the purpose of manufacturing the lamps above described.

THE BESELER ELECTRIC LAMPS AND LANTERNS.

ONE of the most widely known patentees and manufacturers of high grade stereopticons and magic lanterns adapted for electric light, lime or oil light, etc., is Mr. Charles Beseler. His extensive works occupy almost the entire building 218 Centre street, New York, and give employment to a large force of men engaged in turning out stereopticons with arc lamps, for which there is a constant and growing demand. One of his best sellers is the "Bijou" electric arc lamp with hand feed arrangement, as shown in the accompanying cut. The lamp may be used in conjunction with any good magic lantern using either the direct or alternating current. It is of the latest and most improved type, and possibly the only hand-feed lamp that will enable the operator to produce a most brilliant and uniform disc on a screen without flickering. The lower carbon is automatically kept at a given point and only the upper carbon requires feeding by turning the wooden knob at A. B is a patent device for adjusting the upper carbon in order to produce a clear and uniform disc on the screen. No electric lamp can be of much service in lantern work without this important feature.



BESELER BIJOU HAND FEED ARC LAMP.

C is a detachable hood, provided with bayonet catch, so as to admit lower carbon of five inches in length. D is the lever for controlling and feeding the lower carbon automatically; E, the screw for raising or lowering the entire lamp about one inch, in order to reach the centre of the condensing lens accurately. Further details of this lamp, as well as all other specialties, can be got from the manufacturer, whose stereopticon and magic lanterns are used in the electric line for projection purposes as well as in many others, notably in schools and colleges for illustrating purposes. Beginning with the year 1895, Mr. Charles Beseler has been awarded the contract for furnishing his stereopticons and magic lanterns to the city and village schools of the State of New York. The one used by Prof. Albert S. Bickmore, of the American Museum of Natural History, New York City, is of Mr. Beseler's make.

REDUCTION IN PRICE OF BRASS ARMORED INTERIOR CONDUIT.

As will be seen in our columns elsewhere, the Interior Conduit and Insulation Company, of New York City, announce a reduction in the prices of their well known brass armored insulating conduit, elbows and couplings. The enormous sales of this material during the past year have reduced the cost of production; hence the reduction in price.

This company will shortly place upon the market a new and improved iron armored conduit, full particulars of which will soon be given.

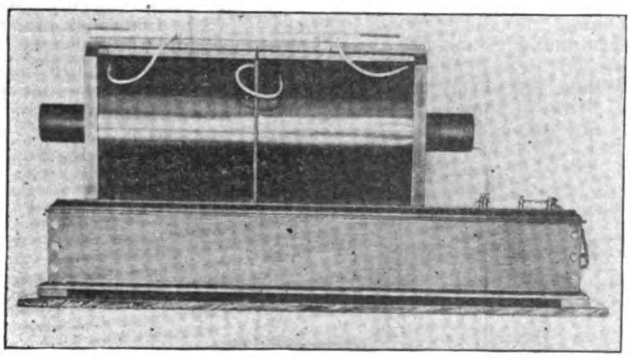
RICHMOND, VA. The Chamber of Commerce has come out in favor of the new anti-Bell telephone service furnished by the new Richmond Telephone Company.

THE ERIE TELEGRAPH AND TELEPHONE COMPANY has declared a regular quarterly dividend of 1 per cent. The earnings are a little ahead of 1895, and so is the net surplus.

THE INTERNATIONAL RUHMKORFF COILS.

THE International Electric Company, of New York, have built up an extensive business in the manufacture of Ruhmkorff induction coils, making a specialty of large coils for colleges and schools.

Among their shipments this week is one unusually large coil, shown in the accompanying illustration, Fig. 1, made for a Western college, and which deserves comment. This coil



12" SPARK RUHMKORFF COIL BUILT BY INTERNATIONAL ELECTRIC CO.

measures 21 in. long and 11 in. in diameter, mounted on a mahogany base 31 in. x 17 in. x 5½, weighing complete about 75 pounds. It is wound in two multiple sections, each containing three smaller ones. The primary wire consists of 246 turns of No. 6 double covered magnet wire. An excellent spark of over 12 in. in length is given by this coil.

A separate vibrator, shown in Fig. 2, is to be furnished with the coil, making it possible to remove both the primary wire and secondary sections.

The vibrator contains a switch and current reverser, and

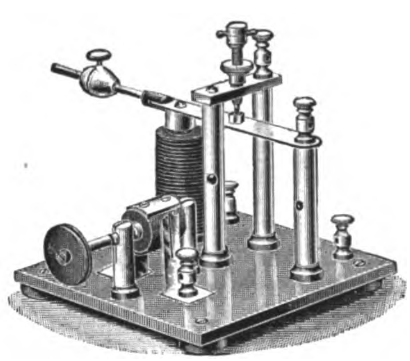


FIG. 2. VIBRATOR FOR RUHMKORFF COIL.

can be regulated to vibrate fast or slow. The platinum points are riveted on and of good proportions. All brass parts are finely lacquered. Twelve volts and 18 amperes are required to operate the coils.

WALKER APPARATUS IN GERMANY.

The Electricitäts-Gesellschaft, Felix Singer & Co., of Berlin, Germany, inform us that they have secured the contract for installing the Walker apparatus on the Upper-Silesian steam railway, which passes through the whole industrial district of Upper-Silesia, this road having determined to transform its traction from steam locomotives to electricity.

The electric system will be introduced at first on the lines (1) Gleiwitz, Zabrze, Koenigshuette, Beuthen, Deutsche Piekar and (2) Koenigshuette, Kattowitz, Laurahuette, Koenigshuette, for which thirty motor cars and a corresponding number of trailers are provided. Freight traffic will also be introduced on the above-named lines.

The cars are mounted on two swivel trucks of 785 mm. gauge. Each of the four axles will be driven by a 20 horse-power motor. The company have the order for the electric installation of these cars, consisting of 120 motors and the whole electrical outfit, including controllers, safety devices, lighting, etc.

The gauge is quite a small one for an electric street railway car having motors mounted in the usual way. This narrow gauge was caused by local conditions. The company, assisted by the Walker Company, whose representatives they are, have overcome these difficulties by devising a new special type of motor for this gauge. The length of both lines is about twenty miles.

ADVERTISERS' HINTS.

THE ELECTRIC ARC LIGHT COMPANY says the "Pioneer" is the best substitute for day light, and not only that, but its quality and cheapness are unparalleled.

THE MICA INSULATOR COMPANY are always ready to supply everything in the way of mica and micanite specialties.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY state that the number of their lamps in use has increased to 10,000 and it has by no means reached its limit.

WM. TAYLOR, 203 Broadway, New York, advertises a twentieth century 150 hour enclosed arc lamp for $19.50 and will forward one on thirty days' trial to prospective buyers.

THE BERLIN IRON BRIDGE COMPANY illustrate an iron truss roof built by them for the Burlington City Water Works, at Burlington, Vt. It is designed to carry a track through the trusses so that coal may be distributed from a car.

THE INTERIOR CONDUIT AND INSULATION COMPANY advertise brass armored conduits, couplings, elbows, etc. By reason of their large sales during the past year they have been enabled to reduce the price on these goods and they will be pleased to mail the new list on application.

THE ELECTRICAL EXCHANGE, Monadnock Block, Chicago, offer some very excellent bargains in dynamos and motors, transformers, street hoods and electrical supplies. They take pleasure in mailing their monthly bulletins to those interested.

PREST. KEELYN, of the Western Telephone Construction Company, informs us that Mr. W. A. Bisland has been elected vice-president of the company in place of Mr. G. F. Stitch, and that the latter is no longer in the service of the company.

MESSRS. WILLIAMS, COUCH & WHITMAN are now located at 196 Summer street, Boston. This change in their quarters was made imperative by the need of greater facilities for the transaction of their increased business. They are the sole selling agents for the United States of the Ericsson Swedish microphone. These goods are standard abroad and, owing to their high quality and durability, their popularity grows each day wherever used.

NEW YORK NOTES.

WENDELL & McDUFFIE, 26 Cortlandt street, New York, sell snow plows, sprinklers, transfer tables, wheels, brake shoes, metallic packing, railroad supplies, etc., and have worked up a large trade in their specialties.

THE CLIMAX GAS ENGINE WORKS, with regard to whose engine an article appeared in these pages last week, has its headquarters at 31 Fulton street, Brooklyn, where it will be glad to answer all inquiries in regard to that specialty.

WALCUTT & LEEDS, 53 East Eleventh street, New York, occupy the entire building there devoted to the manufacture of phonograph or graphophone records and supplies. They manufacture also the blank cylinders and sell also the latest types of the Edison phonograph.

STERLING SUPPLY AND MANUFACTURING COMPANY, 97 Bank street, New York, import and cut to order large quantities of rattan to be used for car sweepers. Recent orders filled for these goods were to the Third Avenue Railroad Company, New York, and to J. G. Brill & Co., Philadelphia. Their registers and brakes are now finding a large market in Australia.

POOR'S MANUAL.—The twenty-ninth annual number of Poor's 1896 Manual of the Railroads of the United States has appeared corrected to August 22,1896. It contains names of all steam railroads, street railway and traction companies, industrial corporations, national, state and municipal finances. It is published by H. V. & H. W. Poor, 44 Broad street (Edison Building), New York.

MR. THOMAS J. FAY has opened an office in the Central Building, No. 143 Liberty street, New York, where he will conduct an electrical engineering business. Mr. Fay will also act as a representative of the Crocker-Wheeler Electric Company in New York and vicinity, in addition to which he has secured control of the sole agency for the Crocker-Wheeler dynamos and motors in Mexico, Central America, South America and the West Indies. Mr. Fay is in position to take hold of any business intrusted to his care, and invites his friends at his new quarters.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. NOVEMBER 18, 1896. No. 446.

Electric Transportation.

THE JUNGFRAU MOUNTAIN ELECTRIC RAILWAY, SWITZERLAND.

In this century of bold engineering one has ceased to be startled at the announcement of stupendous undertakings, but one must confess to a feeling of awe at the contemplation of a work just recently begun, which has for its object nothing less than the building of an electric railroad to the very top of the Jungfrau Peak, in Switzerland. This project, which has been on the tapis for some time, has now been fully organized under the able management of M. Guyer-Zeller, of Zurich, who has received all the necessary concessions from the Swiss Government, and whose faith in the scheme is such that he has himself invested a large part of his private fortune in the enterprise.

In order to realize the extent of the undertaking, we need only say that the Jungfrau Peak is 4,166 meters (13,670 feet) above sea level. Although heights approximating these have been attained in some of the railroads in the Andes, and in the mountainous districts of our own Western States, no such grades as will here be employed have been attempted, and a vivid idea of what the undertaking involves may be gathered from the fact that from the lower terminal at Scheidegg to the Jungfrau Peak, the difference in level is 7,000 feet, which rise will be accomplished in the total length of the road of only 7½ miles. But in addition to the mere engineering features of the road, which are of themselves of great interest, other questions have arisen in connection with the building of this road of no less importance, such as the influence upon passengers of the rapid transportation to such heights as the Jungfrau Peak, as well as a number of aesthetic points, involving the location of the road, so as to avoid detracting from the natural beauty of the landscape.

THE ROUTE.

The route chosen for the road takes account both of the difficulties of the ground and the requirements of the tourists, which it will be necessary to satisfy. Starting from the Scheidegg station, as indicated in the accompanying map, and shown in the view below, the road runs above ground along the rocky wall of the Eiger Mountain to the edge of the Eiger glacier, where the Eiger glacier station is located. From there the road enters a tunnel and follows towards the east, rising with a grade of 25 per cent., which is continued to the neighborhood of the great Bernese wall, north of the Eiger, several yards back from the surface of the wall, so as to allow, if desired, the making of an opening, in order to establish an arcade station within the wall, which station will be called the Grindelwaldblick (Grindelwald View).

The road then continues along the same wall, below the Mittelegi Glacier; there the tunnel takes a large curve, passing through the calcareous layer which forms the Eiger, and passes to the other side southeast of this mountain. The tunnel again follows along the wall, keeping within a few yards of the side, and then it takes the direction from northeast to southwest, toward the Jungfrau.

Under the brow of the Eiger, opposite the superb Vieschwand, a station will be erected, called the Eiger Gallery, a view from which will extend over the entire chain of the Schreckhorn mountains. From this point the line stretches towards the Mönch mountain, following the northwest wall, and, from a vertical, passing under the summit, the line takes the direction towards the Ober Mönchjoch to the rock platform station, called Mönch. This will undoubtedly be one of the most popular stations for tourists, owing to its superb situation. It is in the center of a circle of magnificent glaciers. At the right is situated the Jungfrau Firn, and its magnificent crevasses; at the left is the vast and tranquil Ewigschneefeld (Everlasting Snow Field), almost without crevasses, where even the most inexperienced tourist can, without danger or difficulty, walk and admire at his ease the frozen altitudes of eternal snows, still unknown to the greater part of those who frequent the Alps, and which have been heretofore neglected, owing to the lack of efficient means to observe them from above.

From the Mönch the line continues along a descending grade, passing to the Jungfrau Mountain itself. At that point a double opening permits the tourist to see the two sides of the mountain chain. At one side, towards the south, he will be able to see in its greatest majesty the formidable Aletsch, the greatest glacier in the Alps. From the south side the eye will plunge into the abyss of the Grindelwald, which will be at the tourist's feet, 4,650 feet below. The line ascends to just beneath the summit of the Jungfrau. An

THE "TROLLEY TO HEAVEN." VIEW OF THE EVERLASTING SNOW AND GLACIERS AS SEEN FROM THE JUNGFRAU PEAK, SWITZERLAND.

elevator, with a lift of 330 feet, will then carry passengers to daylight, to the peak itself.

In this way, the Jungfrau line represents a little more than twelve kilometers (7½ miles) of road, ten of which are in tunnel with openings at frequent intervals, the changing views from which will be an incessant delight to the tourist.

METHOD OF CONSTRUCTION AND OPERATION.

As regards the method of construction to be adopted, the successful operation in Switzerland of forty mountain roads employing the rack rail, has decided the adoption of the same type for the Jungfrau road, and the success of the recent electric roads, such as the Salève, and others, with their marked advantages over steam, determined, without question, the adoption of electricity as the motive power.

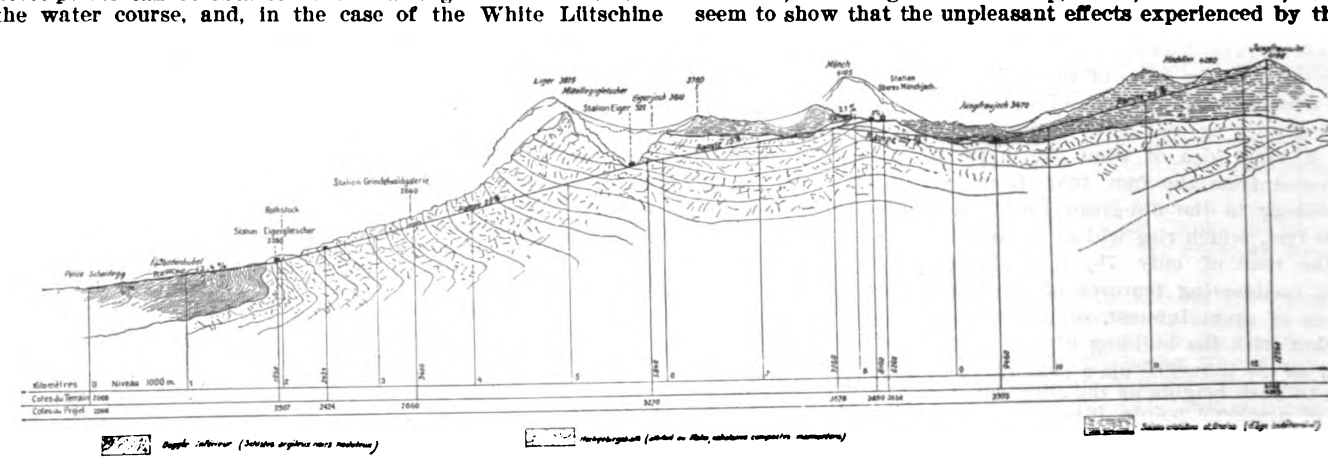
The substitution of electricity for steam is especially advantageous in the case of the Jungfrau road, as regards both the source of power, the boring of the tunnel, and the lighting and heating of the cars. The particular advantage of electricity over steam may be cited as follows: 1, More advantageous ratio of useful load to dead load; 2, more regular, and smokeless operation of the cars; 3, safer meshing of the gear teeth, in consequence of the rotary transmission of the tractive power to the wheels of the vehicle; 4, decreased expense for maintenance and attendance of the cars; 5, saving in cost of operation.

Experience on Swiss mountain roads has led to the adoption in the present case of a one-meter gauge of track, and a minimum curve of 100 metres has been adopted. A maximum grade of 25 per cent. has been adopted, and down-grades will be avoided as much as possible. The heaviest down grade, 10 per cent. will only occur between the Mönchjoch and the Jungfraujoch.

The maximum speed on grades above 15 per cent. will be 8 kilometers—5 miles per hour—and on lesser grades 8½ kilometers.

THE ELECTRICAL WORK.

Power for operating the road will be derived from the waters of the Black and White Lütschine, in Burglauenen and Lauterbrunnen. In the case of the Black Lütschine, 3,000 horse-power can be obtained within a length of 750 meters of the water course, and, in the case of the White Lütschine



PROFILE AND GEOLOGICAL SECTION OF JUNGFRAU ELECTRIC RAILWAY.

1,500 horse-power, within a length of about 700 meters, can be obtained. Assuming as a maximum traffic the simultaneous operation of three trains ascending the road and three trains descending, with two hundred passengers in each direction, or a total of four hundred passengers, a central station of 1,400 horse-power capacity will suffice to operate the road. This power, as estimated, will be divided as follows:

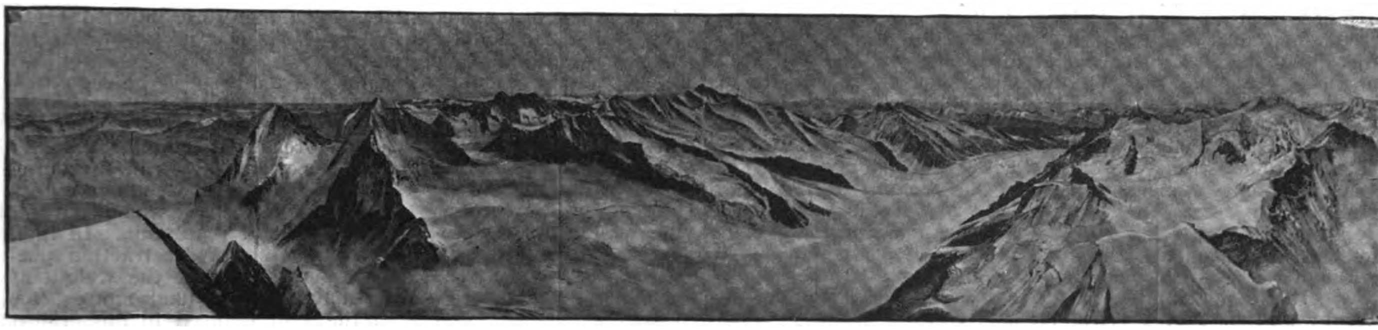
	Horse-power.
1. Current from secondary circuits on the line of the road to the cars	667
2. Illumination of the tunnel	50
3. Illumination of six cars	8
4. Station illumination and elevator	200
5. Heating of six cars, when the outside temperature is 3 deg. C. below zero, and the interior of the cars 17 deg. C., an allowance of 20 horse-power must be made for each car running at 8 kilometers per hour	120
Total power to be delivered by secondary circuit	1,046
6. Counting 10 per cent. loss in the secondary circuit, 6 per cent. in the transformers and 10 per cent. in the primaries, the station will have to be built for	1,325
7. Power required to be given gratis to the corporation of Lauterbrunnen	50
Grand total	1,375

COST OF CONSTRUCTION.

The total cost of this undertaking is estimated at 10,000,000 francs ($2,000,000), which, with elevator, amounts to 780,000 francs per kilometer. According to the charter of the road, the fare from the valley to the top of the Jungfrau and return may not exceed 45 francs ($9), with proportional reductions for passengers going only part of the way. After allowing for 4 per cent. interest on 6,000,000 francs of bonds, the projectors estimate that the road will be able to pay a 6 8-10 per cent. dividend on 4,000,000 francs of stock.

HYGIENIC CONDITIONS.

As the great height reached by the upper terminal of the road is in a region of low barometric pressure, some concern was felt as regards the health of passengers transported to the highest peak. The reports of experts on this subject, however, including that of E. Spelterini, the æronaut, would seem to show that the unpleasant effects experienced by those climbing to great heights are due largely to the reduced vitality of the body, caused by the previous exertions undergone during the ascent; but, as in the case of balloon ascents,

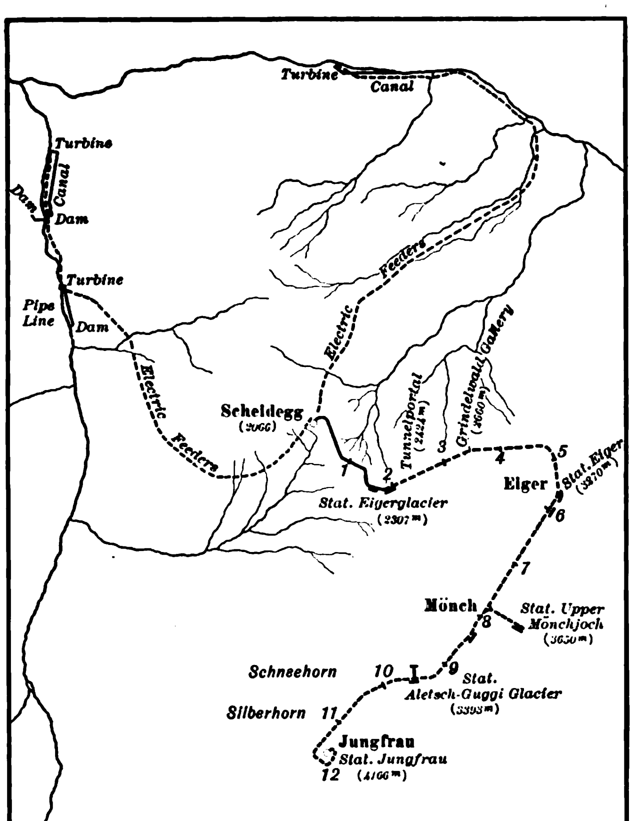


TO BE REACHED BY ELECTRIC ROAD AND ELECTRIC ELEVATOR.—14,000 FEET ABOVE SEA LEVEL.

where no bodily exertion is required, there need be no apprehension on this score.

As cited above, the cars will be heated electrically. This becomes necessary, owing to the fact that the average temperature in the tunnels, it is estimated, will be between 2 and 6 deg. C. below zero up to the Mönch station, and between 6 to 10 deg. C. below zero from that point to the Jungfrau station.

The great difference in temperature of the air at the opposite ends of the tunnel, it is believed, will be ample to set up a circulation of air sufficient for ventilating the tunnel. In fact, it is feared that the currents will be so strong that it



MAP SHOWING ROUTE OF JUNGFRAU ELECTRIC RAILWAY.

may be necessary to close the portals, in order to control them properly, and to avoid the entrance of warm, moist air from below, which will cause the deposit of moisture on the inside of the tunnel, and coat them with hoar frost. At the speed given, it will require one hour and forty minutes' continuous ride to go from the lower to the upper terminal of the road.

It is expected that the first section of the road will be ready for traffic by next August, while the entire road will be completed in five years, each section to be opened as soon as ready.

THE WAUKESHA (WIS.) ELECTRIC COMPANY is to put in a large plant for power purposes.

THE INSTITUTE DISCUSSION ON ELECTRIC TRACTION UNDER STEAM RAILWAY CONDITIONS.—I.[1]

BY DR. CHAS. E. EMERY.

IN the light of recent achievements, it can be assumed at the outset that electric traction under steam railway conditions is feasible. The only question is whether it will pay. The present applications only prove the former proposition, but do not touch the latter.

It does not seem probable, under present conditions, that any probable increase of travel will warrant the enormous outlay necessary to secure electric traction throughout the whole length of our trunk railroads.

The greatest practical efficiency of an electric system of the kind proposed between the engines at the central station and the rails, would probably be 60 per cent. This, on account of a second transmission to sub-stations and the necessity of using rheostatic regulation to some extent, would probably be reduced to 50 per cent., so that twice as many horse-power would need to be generated at the central station as at the track with the present steam locomotives. Each horse-power in the central station will be developed for two pounds of cheap coal or four pounds per net horse-power delivered, whereas the steam passenger locomotive will on the average require six pounds, based on net tractive force and allowing for the various wastes. The saving in coal due to electric passenger traction will therefore be one-third. Coal is procured cheaply by the railroads, but probably an inferior quality, costing 50 cents per ton, or, say, 25 per cent. less than that used on locomotives, could be employed in the electric stations, so that, for trains of like weight, the saving in cost of coal for passenger service would be $\frac{3}{4} \times \frac{2}{3} = \frac{1}{2}$. For freight engines we calculate the saving in cost for fuel will be about 55 per cent., and for switching engines about $66\frac{2}{3}$ per cent. On railroads running through the coal regions the total cost of coal is about 9 per cent. of the total operating expenses. A saving of one-half in the cost of the coal then corresponds to a saving of 5 per cent. of operating expenses. For reasons that will be stated later, it is believed that, for general railroad work, independent electric locomotives will be required, and that these will necessarily be as heavy as present steam locomotives, on which basis the only saving in weight will be that of the tender, which we have assumed as 10 per cent. of the total weight of the train for passenger engines, 3.3 per cent. for freight engines, and 5 per cent. for switching engines. The total load to be hauled will therefore be decreased by these several percentages, and the cost of coal reduced thereby to 45 per cent. of that required by the present locomotives for passenger trains; $43\frac{1}{2}$ per cent. for freight trains, and 32 per cent. for switching trains. Applying these percentages for the relative amounts of coal used for these different purposes on a prominent railroad, the average saving in fuel becomes 58.9 per cent., or 5.89 per cent. of operating expenses. The cost of water is taken at $\frac{2}{3}$ of 1 per cent., on the same basis which increases the saving to 6.56 per cent.

Considerable saving has been claimed on other grounds. First, in relative repairs of electric motors compared with locomotives. Repairs will be less on the motors, of course, but are not inconsiderable, and when we consider that the transmission line, trolley line and trolleys must be kept in repair as well as the motors, it cannot be far in error to assume that

[1] A topical discussion at the 109th meeting of the American Institute of Electrical Engineers, New York, Oct. 21, and Chicago, Oct. 28, 1896.

the question of repairs will be about balanced, independent of central station apparatus otherwise provided for.

It has been claimed that labor will be saved, because the second man on an electric locomotive is required simply to provide for sickness or accident of the driver, and can well be the baggageman of a passenger train or the conductor of a freight train. Something of this kind may be worked out on an unimportant country road, but it would be impracticable on a large business scale. If a trunk line were to be changed to electricity to-morrow, the best policy would be to keep the old engineers to operate the locomotives and learn of electricity as fast as possible, and to put the young men from the training schools of the large companies as the second men to watch electrical details and overcome unforeseen contingencies, the firemen taking their places as they learn how. It is also claimed that there will be a saving in the weight and cost of electric locomotives, particularly when applied under a car, but this system is of limited application. Heavy locomotives on trunk lines must have the same weight for electric as for steam traction, independent of the tender, as explained hereafter. Large savings in repairs to tracks and bridges are also claimed on account of the smoothness with which electric locomotives, having no reciprocating parts, would operate. The same weights must be run over the same rails at the same speed, and at least a great part of the wear and tear would be due to inequalities of the track surface, which would influence both systems alike. The present locomotives are so designed that, while the wheel loads on the drivers are heavy, the masses which strike blows are comparatively light; that is, they have simple wheels and axles, spring-connected to the frames. This is a very difficult thing to accomplish with an electric locomotive without using exactly the same construction. On a comparatively smooth track, remarkable steadiness of movement may be obtained, if the armatures of the motors are secured to the axles of the driving wheel and the fields supported concentric therewith, but such an arrangement is entirely unfitted for a railroad track in average condition. Springs only relieve the frame. Each pair of wheels and attached motor acts as an enormous trip-hammer on the rails and roadbed the moment the former gets the least out of alignment, by defect in original construction, by settling after rains or from other causes. A connection to driving axles through gearing reduces the blows very materially, but introduces at high speed another difficulty. The vertical movements of the main axle would necessarily cause a change in the angular velocity of the armature during the time of such movement, which, for jars occurring in the fraction of a second, would bring a heavy strain on the gearing and vary the speed of the armature momentarily. The variations in current due to such variation may also give a longtitudinal pulsation to the train. The matter is not helped at all by mounting the motors on hollow axles concentric with the driving axles, so that the motors may be spring-supported from the axles, for in such case the connection of the motor to the axles must be through links the equivalent of a universal joint, which produce variations in velocity, when the axles are out of centre with the armature, similar to those where gearing is employed. In fact, these very devices are used to obtain variation in angular velocity in many machines. Either gearing or universal joints would have back lash when current was shut off. The suggestion recently occurred to the speaker, and he has not had time to calculate the effect of these considerations, but they must be serious. A train at 60 miles an hour moves about 90 feet a second, sufficient to cover a number of yielding rail joints in that time. When the New York Central Railroad started its fast trains, the engineer found it necessary to go over the alignment with instruments; as dips and vertical curves, which would not be noticed by the trackmen, gave very unpleasant motions to the cars at high speed.

For reasons above given, it will be necessary to mount electric motors for fast locomotives away from the centres of the axles and connect through side rods, as in the present locomotives. The only other method would be to use chains, which are mechanically impracticable. There is another important reason for this. In order to obtain speed, the motors must be wound for it so that the counter-electromotive-force will be produced by velocity rather than the number of turns, and, in starting, the motors are necessarily connected in series so as to reduce the starting current. For motors adapted to very high speeds, it will be necessary to put pairs in series even to surmount heavy grades, to act as pushers in case of accident, or in removing snow, etc. The counter-electromotive-force is therefore divided between several motors, but not necessarily in equal degree. If, with motors connected to separate axles, one for any reason slips its wheels, it will monopolize the larger portion of the electromotive force and cut down the current on all the motors in series, so that full power cannot be obtained. Working the motors in parallel with an enormous rheostat would be wasteful, and, in some cases, impracticable. It is, therefore, important for two reasons to connect driving wheels operated by separate motors by means of side rods.

Again, it is essential that, on the road, speed be regulated by better means than a rheostat. A series motor varies its speed with the load and so cannot run without rheostatic regulation at a given speed if for any reason the number of cars in the train or the track resistance varies. It will, therefore, be necessary to return to commuted series field coils or equivalents, and it will be perhaps desirable to have a shunt winding which can be used to give still closer regulation. In fact, shunt motors are being introduced abroad for traction purposes. The use of these devices will increase the weight of the motors compared with simple series wound motors, for the simple reason that with the field reduced to the utmost it must still be sufficient to prevent sparking, and there must be sufficient iron employed to make the stronger field efficient when it is desirable to run slower. These considerations make more room desirable for the motors than can be provided in the trucks of an ordinary car.

For these several reasons it is predicted that the high speed electric locomotive of the future will, like the steam locomotive, be a structure independent of the train, that the motors will be hung on the frame independent of the driving wheels, and the same as well as the driving wheels connected by side rods. To obtain proper room under such conditions larger driving wheels will be employed than the wheels of an ordinary car. This will so extend the wheel base that it will not be safe to run at high speeds without the leading truck, the same as on an ordinary locomotive, and, in fact, the electric locomotive will in all its general features be a steam locomotive without the boiler, with motors substituted for the steam cylinders. In this way and probably in no other can the flexibility of the present steam locomotive be obtained. Probably there will be greater difference of opinion on this subject than on any other. The use of motors in the trucks of baggage cars is so fascinating that strong efforts will be and should be made to retain such a system, though the reasons stated are believed to be sufficient to prevent its general adoption. Again, it is desirable that the whole locomotive be a unit, on a strong frame, calculated to resist the shocks due to collisions and accidents, and it is doubtful if locomotive drivers will be found who will be willing to risk their lives on any other kind of a structure.

To realize the flexibility of the ordinary locomotive one has but to go on the line of one of the roads which has not yet adopted the heaviest type of rail, but yet runs express trains at 45 miles per hour, grasp a convenient post close to the line and a little around a curve, if possible, where one can take the wind of the train, and watch its approach. In many cases the locomotive sways nearly a foot from the perpendicular, first one way and then the other. At a bad joint the plunge is so rapid that the effect can be described as terrific, as one cannot but think of the consequences if such a mass should leave the rails. The locomotive, however, follows the inequalities as readily as would a farm wagon. Electrical engineers may insist upon a more rigid and better track, but this will require additional expense and will not entirely overcome the difficulty. The electric locomotive must be constructed so that it will do the work of the present locomotive in the same way, and the feature of flexibilty cannot be sacrificed.

A modern heavy locomotive costs about $10,000, which is at the rate of $10 to $12 per horse-power, on about the same basis as electric motors would be rated. It needs little argument to show that an electric locomotive, to take its place under conditions stated, would cost fully as much. Moreover, if like care is to be taken of electric locomotives as of those for steam, the same number must be employed of like capacity for like work.

An approximate calculation of the cost of electrically equipping and operating a trunk line has been based on information in regard to the operating expenses of different railroads, given in the series of articles by Mr. Baxter, in The Electrical Engineer early this year. We have the highest respect for the industry and ingenuity of Mr. Baxter, as he was one of those who rendered valuable assistance to the speaker in carrying out a large enterprise a number of years ago, and we have adopted his facts, and for convenience have used some of his methods, but have been obliged to entirely disagree with his conclusions. For instance, we calculate that the cost of the steam and electric generating plants will be about three times as much as he states, the transmission plant and sub-stations about twice as much, and the operating expenses about 5½ times as much as he provides for. Necessarily the conclusions are diametrically opposite.

The calculations are based on the operating expenses of a railway system, comprising nearly 2,700 miles of road and employing 1,800 locomotives. By calculations based on the train miles, checked by the reported coal burned, and the probable number of engines in use, Mr. Baxter ingeniously determines an average of 140,000 horse-power, considered as continuously operated, which, in our calculations, we estimate will require to replace it 280,000 horse-power in the stations, on the basis of 50 per cent. efficiency from stationary engine pistons to track, and if 60 per cent. can be obtained by commutated fields, or other means herein discussed, the difference simply provides for an expected increase of travel. From the probable average power and the actual reported operating expenses corresponding thereto, we proceed as follows: For facility of calculation and to obtain an underestimate, rather than one too large, the power required for the switching engines is distributed among the regular trains on the road. It is also assumed that the average number of trains is continued the entire length of the road, instead of using a much greater number than the average for suburban travel. These methods cause an underestimate of the cost of the electric transmission, but enable the cost of operation to be accurately worked up from the averages. The latter is the more important point, as the other merely involves comparatively small questions of difference in the amount of interest. By this generalization the trains will be assumed as separated about 7½ miles, independent of direction, over the whole length of the road for every hour in the year. On this basis there will be required on the average 106 station horse-power per mile of road, independent of direction of trains, but to provide for concentrations which will inevitably occur, the generating plants and transmission lines have been worked out on the basis of 150 horse-power per mile. The assumed number of trains will require on the average about 400 horse-power each at track, or 800 at station, which is high for an average, as the power of the switching engines is, as explained, distributed along the whole line for convenience of calculation on the basis of averages. To obtain the economy due to fairly large stations they are assumed to be separated 45 miles from each other, and at two intermediate points transformers and rotary converters (transformers) located, by which means the feeders are supplied every 15 miles. On the above basis it is assumed that 6,750 horse-power is installed at each steam station, and 2,250 horse-power at each sub-station. To avoid overestimates the cost per horse-power of steam and electric plant in main stations has been assumed as only $80 per horse-power with $20,000 for buildings, and for the whole apparatus in the sub-stations there has been allowed only $10 per horse-power and $10,200 for buildings and the copper in the high tension lines. The low tension copper has been worked out on the basis that half-way between the main and sub-station two trains may meet, each requiring 1,000 horse-power, and that a uniform section of copper sufficient to carry 7½ miles, the current required for half of this power, at an original tension of 700 volts and a drop of 20 per cent., would be ample for the whole length of the low tension lines. On this basis the cost for copper at 13 cents per pound for the outgoing low tension conductors will be $12,386 per mile. It is assumed that provision for supporting the outgoing conductors and the bonds in main track for return current will cost $5,000 per mile. On the basis of these prices, without considering incidentals, the total cost of the electrical generating and transmission plant foots up $31,057 per mile, the annual interest on which, at 5 per cent., is $1,553 per mile. If the services of the 1,800 steam locomotives can be furnished by 1,500 new electric locomotives at $10,000 each, the same will cost $5,556 per mile, requiring $278 annual interest per mile, making the total interest on steam and electrical plants, including locomotives $1,831 per mile. The operating expenses of the station considered as a steam station only, from Emery's tables reduced to 24 hours and 365 days, modifying cost of plant and eliminating coal and interest, is found to be $25.84 per average horse-power per year. The time of 12 extra men for care of electric apparatus in the main and two sub-stations amounts to $2.75 per horse-power per year, which makes the total operating expenses of the generating, transmission and locomotive plants, exclusive of coal and interest, $28.59 per average main station horse-power per year, or $3,031 per mile. or, with interest added, viz., $1,831, as above, a total of $4,862 per mile. The operating expenses of the station thus calculated include an allowance for repairs, insurance, taxes and renewals. It should be recollected that the cost of coal has been already provided for in the percentage of saving first developed, and that the train expenses are assumed to be the same as for steam locomotives. The operating expenses of the road using steam, amounted to $15,187 per mile. Of this, as previously stated, 6.56 per cent. will be saved by the use of electricity, corresponding to $996 per mile. This, substracted from $4,862 per mile (given as the cost of operating expenses of the generating stations, etc., with interest added), leaves $3,866 per mile per year as the additional expense which will be entailed by the application of electricity as a substitute for steam; so, on the basis that the operating expenses are 50 per cent. of the gross receipts, such gross receipts must be increased 12¾ per cent. by the introduction of electricity over the whole length of the line, in order to enable the road to pay the same dividends as before.

It may be considered that the results will be changed materially by the use of high-tension transmission throughout. If tri-phase currents at a tension of 10,000 volts were received by each electrical locomotive, the tension reduced by transformers carried by the locomotive, and current employed to operate induction motors directly, or to operate direct current motors through rotary converters also carried by the locomotives, the saving independent of extra transformers and converters would amount to $9,714 per mile, corresponding to $486 interest per mile, and reduce the total increased operating expenses to $3,380 per mile, which would require that the gross receipts be increased 10.2 per cent. in order to pay the same dividend as before, instead of 12¾ per cent., for combined high and low tension transmission. The saving in dollars is quite large, but the total costs are so enormous that the saving makes but a small difference in percentage. It will similarly be seen that differences in kind of apparatus employed will have very little difference on the general results, though the savings are important in themselves.

It must be recollected that these results are based on providing electric traction for the whole length of a trunk line. It can hardly be expected that the gross receipts for the whole line will be increased, say, one-eighth by such an application. If, however, the application be made within the radius of suburban traffic such an increase is not only probable, but it may be expected that the cost of operation per passenger mile will be reduced in greater proportion than stated, so that the application of electric traction will pay from the outset. These considerations will apply to longer distances on railroads like the New York, New Haven and Hartford, where the passenger business furnishes the larger proportion of the income.

Again, it is possible to accomplish with the electric locomotive results that are impossible with the steam locomotive. The power for the former being generated originally in stationary boilers, or in some localities derived from waterfalls, is not limited, and the power of the motor can be increased indefinitely, so that in particular locations a demand either for greater power to obtain more speed, or a greater or more continued tractive force than is now possible with a steam locomotive, can be met by electricity without difficulty.

On the whole, therefore, although the application to the whole length of long trunk lines does not seem practicable under present conditions, there is no doubt but that the industry will grow in the future as certainly as in the past.

A LONG ROAD FROM MILWAUKEE.

The Milwaukee, Racine and Kenosha Electric Railway Company, with headquarters at Racine, has filed articles of association with the Secretary of State with the purpose of building and operating an electric street railway system from South Milwaukee northerly through Cudahy and the towns of Lake and Oak Creek, then south through the towns of Caledonia and Mt. Pleasant, city of Racine, towns of Somers and Pleasant Prairie and city of Kenosha. The capital stock is $250,000; incorporators, George H. Hopper, Edmond Deane and Park Phipps. The officers are M. Slush, president; A. W. Bishop, vice-president, and G. J. Hoffman, secretary and treasurer. The plant is now in process of construction. There are 16 miles of circuit and two of "Figure 8" size No. 3. The power plant comprises two 400 kilowatt Westinghouse generators, two 600 horse-power Westinghouse engines and 1,200 horse-power of Stirling boilers. The road equipment comprises six 100 horse-power Walker motors.

A LONG ELECTRIC ROAD FOR CALIFORNIA.

Mr. John F. Byxbee, the secretary of the Santa Rosa & Sonoma County Electric Railway Company, writes us that a franchise has been granted for this interesting enterprise. The road is to make a circuit of 110 miles through the Sonoma and Napa Valleys, uniting two of the most fertile and prosperous regions in the State. The company is pushing its plans forward actively, and expects to begin construction in 60 days on the first section of 30 miles, from

Santa Rosa to Sonoma City. That section is to be ready by June, 1897, in order to take care of the large summer travel. It is expected that about three years will be required to finish the whole road. Mr. Byxbee's headquarters are at 42 Market street, San Francisco.

MODERN OVERHEAD CONSTRUCTION.—II.

BY BENJAMIN WILLARD.

(Concluded.)

THE holes for eye bolts should be bored in wood poles before their erection, and should be bored so that the bolt will incline slightly downward toward the eye to prevent the water from following in and rotting the top of the pole. The correct location for eye bolt holes would be determined by the height at which the trolley wire is to be placed, 22 feet from the base of the pole would be correct, assuming that we allow 2 feet for drop in the ear body and ear and also dip in the span which would make the height of trolley wire about 20 feet. To facilitate the setting of poles to a uniform height it is a good plan to place grade stakes near the location selected for poles indicating a given height relative to the grade of the track.

Center pole construction is required in many locations and may be more adaptable than other methods, but I consider span construction better, owing to its flexibility and for being less unsightly. There are now on the market appliances for making bracket suspensions flexible, which are an improvement over the old type of rigid construction. One of the most practical which I am familiar with is an attachment to receive a short span of flexible wire and the ordinary straight line hangers.

Poles used for center and bracket construction should be made according to the same specifications as those used for span construction, excepting that an ornamental pole top would be required for the steel pole instead of an insulated one. Much can be spent on ornamentations on center and bracket construction, but it always occurred to me that the most practical is ornamental enough and places the cost where it will do the most good. For the bracket arm a 1½ in. pipe of the required length attached to a malleable iron collar made in halves and encircling the pole and supported by truss rods leading from the end and center of the arm to near the top makes excellent and neat appearing construction.

Wherever guard wires are required, it will be necessary to leave about 2 feet additional space on the top of the pole above where the trolley span wires are attached for the attachment of the guard wire span. It would hardly be practical to provide an insulated pole top to provide for both span wires, so the trolley span would be supported by means of a wrought iron clamp collar encircling the pole at the proper point and provided with suitable insulating fastenings. I do not especially approve of this method of construction (as I do not favor guard wires), but I would recommend it where it is compulsory to erect guard wires.

All poles should be painted with one coat before their erection, as it affords better opportunities to carefully apply the priming coat and at less expense than after the poles are set. A paint of dark green composed of graphite mixture I find to wear well, and although it costs more than some other paints, it has better lasting qualities, especially in iron work. A second coat of this paint, after the poles are erected, will cover marred places made necessary in setting, and will look well and last for at least two years.

Span Wires.—Span wires necessary for trolley suspension should be flexible steel 5-16-inch in diameter, composed of 7 strands of No. 12 galvanized wire, and when under strain with conditions of pole setting, as I have stated, would have a tension of about 750 pounds when erected. Whereas I have allowed 18 inches for sag in the span, it probably would not be over 12 inches at the time the wire is first suspended, but will gradually sag more as the wire stretches and the poles spring or yield in the ground, so if a 40-foot span is attached 22 feet above the rail surface the trolley wire within the course of a year would measure approximately 20 feet above the rail.

Where wood poles are used, or wood pole tops for steel poles, the ordinary ⅝ inch x 12 inch eyed-bolt threaded 4 inches answers every purpose for the attachment of the span wires, and other devices more expensive used for the same purpose are not necessary. Poles when properly set will bear a given strain on the span wires for many years without much yielding, consequently an adjustable device is rarely if ever used. Hard drawn copper trolley wire of No. 1/0 B. & S. gauge has been found to be the most practical dimension of wire and is generally considered a standard for most trolley construction; therefore, overhead appliances are made of various manufacture to meet such requirements. There has been a trolley wire recently manufactured in the form of a figure "8," which is now in use on some roads and has given very good results. Where this wire is used it leaves a perfectly unobstructed surface for the trolley wheel and gives greater current carrying capacity, but in modern construction the hanging appliances have reached such a degree of perfection that the round wire can be used with equally good results, and as the trolley wires on large systems are relied upon but little as a conductor for current capacity, I can hardly recommend anything that would be more practical than the round wire.

Span wire hangers and insulators are of various forms and compositions, and many possess equal merit, and I would recommend for straight line work those most indestructible and possessing the best insulating qualities. The best forms of such hangers are those where the insulation is concealed from the weather as much as possible, and having a metallic covering to prevent them from being broken by accidental contact of the trolley pole. Brass hangers are more expensive than iron, but resist the moisture and are maintained at much less expense. Iron hangers if kept in good condition should be painted at least once a year, as the oxidation, if allowed to accumulate, will form a conductive contact between the conductors and span wires, and in course of time will cause the escape of current by leakage. Hard rubber insulation for hangers is more expensive than many other compositions, but from my experience must say it has fine insulating qualities, and stands different conditions of climate with little or no deterioration.

Suspension ears are of as many varieties as hangers, and I have experienced the use of many such appliances and have concluded that a little modification of the old brass solder ear is the most practical and lasting of all, if properly attached. A solder ear should be 15 inches in length tapped for ⅝ cap bolt and provided with thin lips at either end, so dimensioned as to encircle but little more than half the trolley wire, and one point which should be observed very particularly is to have the ends of the ears ground to a thin tapering end, so that they will become flexible with the vibrations of the wire. If the ends are made heavy or unyielding, the vibrations will have a tendency to detach the ear at the points, and when this takes place it is a question of a short time before the ear is wholly detached.

Insulators and hangers for curve construction like straight line material, are of many designs and permit of wide selection. However primitive may seem my ideas of this particular part of construction, I can only give good results from my experience. I favor what is known as the goose-neck hanger, which is simply a ⅝-inch steel forging formed of such dimensions as to allow good clearance for the trolley wheel and fastened to the soldered ear in a manner to permit it to swivel, also provided with an eye for the attachment of pull-over wires. Such devices are strong, and do not present an unobstructive object for the trolley to catch in. There is no insulation attached to such ears and this is the only thing in their disfavor, but as there are many insulating devices, which can be attached to the hanger, to overcome this difficulty, this could be considered a minor point.

A great deal could be said about overhead curve construction, but there are so many different conditions to meet I will simply conclude my description with a double right angle curve of 60 and 50 feet radius. The pull-off ears should be placed 11 feet 8½ inches apart on the outside curve, and those on the inside curve 9 feet 10 inches apart from center to center (commencing at point of curve), so that the pull-off wires between the two curves run longitudinally from the axis of the track curves. The three central pull-off wires leading to the center pole would terminate in an iron ring 3 inches in diameter fixed at a point about 20 feet from the trolley wire and attached to a single ⅜-inch cable fixed to the center pole by ending in a strain insulator. Each of the other pull-off wires would lead directly to their respective poles, all ending in a strain insulator fastened to the pole top. Each of the suspension ears should be placed directly perpendicular over the track centers and each provided with a strain insulator between the trolley wire and pole.

There is a wide difference of opinion relative to the arrangement of sections and the methods of feeding such sections of the trolley wire. In many installations a practice is made of leading each individual section feeder to the station and separating the trolley into sections by sectional insulations, making it possible to cut out the various sections at the power house. This is a convenience in one respect, and that is, it makes every section of the line directly controllable from the power plant; but there are other things equally as important to consider which may convince you that better results are obtainable through another method, and that method would be to have every feeder on the whole line doing a share of work

at all times, whether the cars be assembled on one section or distributed over the entire line. This, of course, can only be done by means of connections representing the whole line as being in one general section, making short sections controllable by external switches. In the first method mentioned an accumulation of cars may be assembled on one section not estimated for carrying an abnormal load, consequently the feeder would be overtaxed on this particular section, whereas the feeders on others sections would be doing little or no work, consequently, an unevenness of potential between the adjoining sections. If there is a bridge around each section insulator connecting each section together and connected by a feed wire so that the current will equalize itself between two sections the current will distribute itself from all feeders; then we have a small amount of variation of potential from section to section, and every feeder is auxiliary to each other.

I have observed in most all instances that when an accident occurs to a trolley wire the whole line is for a time disturbed in its service until the proper attention has been given to the external circuit where the trouble occurs, and those on the ground are the ones who are depended upon for relief before the forces at the power house are aware of the extent of the trouble, and the switchboard tenders are always under instructions or advice from the emergency crew. Consequently, I maintain that efficient external line appliances that are controllable by emergency forces meet the most important requirement, and the most efficient line can be built with a general feeder system leading from the switchboard and controllable as a whole for each individual line, and not separated into sections requiring separate feeders for each section leading from the station. To accomplish this method of uniting the trolley sections the line is divided into sections by means of sectional insulators, each section so proportioned as to meet the estimated feeding point where the feeder is to be attached. A switchbox is placed on the pole (at a convenient height), in which are contained two switches and fuses, one for the section on either side of the sectional insulator; the feeder is then divided by connection through each switch so that the feed wire delivers current to either section through feeder span wires attached to connections on each side of the sectional insulator. When the entire line is in operation there is an equalization of current in all sections and the trolley remains virtually as a solid conductor, but with all necessary features for disconnecting the sections.

Feed wire distribution is an important item in all installations and varies with local conditions such as distances, amount of work to be done, and cost of producing power. As this is a mathematical problem that is made fitting to meet each of the local conditions, I will only undertake to define a general system for erection and distribution.

In most localities where a large system of feed wire distribution is required it is necessary to erect special construction for that purpose. The most economical plan is to select centers of distribution reached by the most direct routes from the power station and established at such points that may be called junction poles to which are attached the heavy trunk line feeders leading from the power plant, and smaller feeders for distribution to the trolley line. By this plan we may erect wires of 500,000 or million circular mils capacity from the plant to the junction pole, and end same to a junction frame or frames attached to the pole which is provided with a bus-bar of sufficient carrying capacity to carry the current of the branch feeders. The large cables are dead ended in the junction frame by use of eye-bolts and strain insulators, and connections are made with the bus-bar with copper tee connections. The branch feeders are ended and connected in the same way, so that it is possible with little delay to cut out any feeder and make changes which are often necessary during progress of operation.

Southern pine cross-arms, 5 inches by 3½ inches, bored to receive 1½-inch pins, and doubled on each pole, will make sufficiently strong construction to receive the heaviest wires. The pins should be of locust wood bored to receive a ½-inch bolt, which should extend vertically through the center of the pin and terminate with a washer and nut on the under side of the arm.

Top grooved glass insulators are desirable in all classes of heavy feed wire construction, and their adoption is to be recommended. Feed wire conductors of larger area than 0000 B. & S. gauge should be in stranded or in cable form triple insulated with the best waterproof covering. Care should be taken in splicing cables, so that an even strain is brought on each smaller wire and that they are are not allowed to remain without good contact, and that all flux used in soldering is carefully removed before tapeing. Devices have been used for connecting cables, but none are to be recommended in favor of the splice made with the cable itself.

Protection from lightning is now occupying the attention of many railway companies, and there is a wide difference of opinion relative to merits of lightning arresters and their application. I have received correspondence from many different railway companies, and in one instance there are two arresters located for forty-two miles of road, whereas in another instance there were six to the mile. The general idea seems to be two to the mile, and situated at or near the junction where the feed wire is attached to the trolley wire. It is somewhat difficult for me to explain all the details of construction in a manner to be digested intelligently in the mind without referring to some illustrations covering the points in question, so I have furnished the association with some photographic illustrations which may be used in conjunction with my description.

ELECTRIC TRACTION FOR KINGSTON, JAMAICA.

Kingston, the capital of the British West Indies, with a population of about 50,000, is going to put in a trolley system. The Jamaica Street Car Company, Limited, has applied through the Hon. S. C. Burke, its president, and Mr. H. E. Squire, its secretary, for permission to equip the lines electrically. About ten miles will be built. The company is an old and prosperous one, having operated for many years past, using mules as motive power.

TROLLEY TO LEAGUE ISLAND FROM PHILADELPHIA.

A director of the Union Traction Company, when asked whether the company would view favorably the matter of the construction of a branch to the League Island Navy Yard, as suggested by the report of the Committee of Councils, said he could not speak for the Board of Directors, but thought the project might receive favorable consideration if City Councils removed some of the expensive conditions which are attached to trolley franchises granted in the last three years. A line to League Island from Jackson street, constructed in a substantial manner, but laid with "T" rails, without paving and the feed wires overhead, would cost, it is said, in the neighborhood of $20,000, and at the present time there would be little travel beyond what goes and comes from the Navy Yard.

MECHANICAL.

THE AMERICAN MECHANICAL STOKER.

BY C. H. BIERBAUM, M. E.

AMONG the modern engineering developments in the line of mechanical stokers, may be mentioned one of special interest the "American Stoker" made at Dayton, Ohio. The accompanying cut, Fig. 1, illustrates the single stoker.[1] Immediately beneath the coal hopper, and communicating with it, is the conveyor chamber, this in turn communicating with the magazine in direct line with it. A screw conveyer, or worm, is located in the conveyer chamber and extends nearly the entire length of the magazine. Immediately beneath the conveyer chamber is located the wind-box, having an opening directly beneath the hopper. At this point is connected the piping for air blast. The other end of the wind-box opens into the air space between the magazine and outer casting or envelope.

The upper edge of the magazine and envelope are surmounted by tuyere blocks, these tuyere blocks being provided with openings for the discharge of the air blast. Beneath and in front of the hopper, is located the motor for operating the stoker. These motors are simple piston steam engines. The piston rod of the motor carries a crosshead, which, by means of suitable conecting links, operates a pawl mechanism, which in turn actuates the ratchet wheel mounted on the conveyer shaft.

The space on each side of the stoker, between the tuyere blocks and the side walls of the furnace, is occupied by dead-plates, or an air-tight grate.

Furnaces over six feet in width, too wide for a single stoker, are equipped with the double stoker, shown in Fig. 2. This double stoker is the combination of two single machines, feeding from a common hopper. and operated by the same motor. The coal is fed into the hopper, carried along by the conveyer through the magazine, overflows from it on both sides, and spreads upon the dead plates the entire width of the furnace. The entire mass of coal above the tuyere blocks and all of that upon the dead-plates is ignited, carrying a bed of burning coke from fourteen to eighteen inches in depth.

In the usual hand firing conditions the natural tendency for

[1] An illustrated article descriptive of this apparatus will also be found in The Electrical Engineer, Vol. XX., No. 395, Nov. 27, 1895, p. 535.]

the air is to pass through the bed of coal, where it finds the freest and easiest passage. This would be at the points where the bed of coal is the thinnest, where naturally the least amount of air is required; and, conversely, the least amount of air is supplied to the parts of the fire where it is thickest, where the greatest amount is required. This tendency has the effect of burning holes into the fire. By common experience, every practical fireman knows that a fire with these holes burnt in it is wasteful, owing to the excessive admission of cold air into the furnace.

In order to overcome this wasteful tendency, frequent slicing and firing is required. This, in turn, requires the fire doors to be opened at short intervals, and again means an admission of a large quantity of cold air through the fire doors, thus the waste due to an excessive use of air cannot be avoided under the ordinary conditions of firing, though care may greatly reduce this loss.

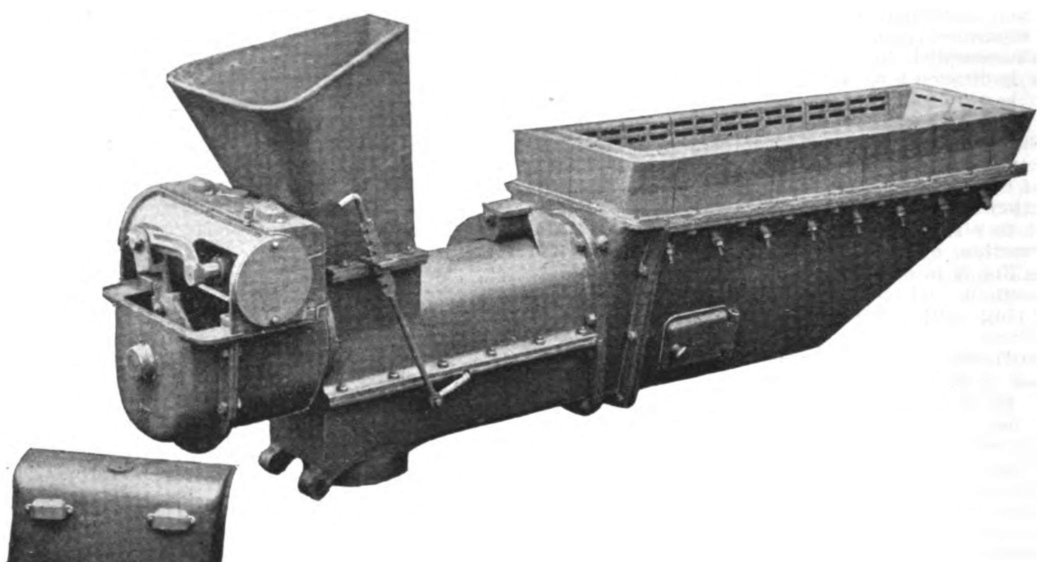
The greatest loss in any boiler plant is the loss of heat carried away by the chimney gases. This, to some extent, inevitable loss, in common practice amounts to from 15 to 35 per cent. of the total heat generated in the furnace. The temperature of the chimney gases depends upon the temperature of the absorbing surfaces and the velocity at which these gases sweep over these heating surfaces.

It is, therefore, evident that the temperature of the gases must be higher than that of the absorbing surfaces, i. e., the temperature corresponding to the steam pressure in the boiler; largely detracting from the value of the stoker as an economical adjunct.

Another economic feature of this stoker is the complete combustion of both the solid and gaseous portions of the coal. The bed of burning coal being deep and having forced draft, melts the incombustible portions of the coal into a clinker, which accumulates on the dead-plates on both sides of the furnace in a compact mass, almost entirely free from any trace of coke. The comparative results show that the amount of ash is reduced from 2 to 8 per cent. This means that the amount of coke and coal in the ash is reduced by an amount equal to the reduction of the per cent. of ash, and since a pound of coke is worth more than a pound of ordinary coal, the per cent. saving, due to non-waste of coke ash.

It is quite evident that none of the gaseous constituents of the coal can escape perfect combustion under the conditions of operation. The green coal being fed from below the bed of fire, liberates its hydro-carbons or gaseous constituents upon coming in contact with the fire. The air being supplied at this point where the hydro-carbons are evolved, is thoroughly mixed with them, this mixture then passing through the deep bed of incandescent coal.

A problem next in importance to that of the economic use of coal, is perhaps that of smoke prevention. Large sums of money have been expended in experiments, without a sufficient regard to the simple laws of smoke formation. Smoke



The New American Stoker.

the lowest possible temperature that could be attained would be that of the heating surfaces if the gases had no appreciable velocity whatever. Thus, in order to reduce the chimney losses under given conditions, it is necessary to reduce the volume of air used, in other words, use the air more economically.

As the result of a long series of chemical analyses of these chimney gases collected under precisely similar conditions, both when fired by hand and by the stoker, it is shown that the amount of air required per pound of coal when burned with this stoker is from 20 to 55 per cent. less than that which would have been used in the common hand fired practice. This effects a twofold economy, in decreasing the volume of heated gases passing up the chimney and likewise decreasing the velocity of the gases as they pass over the heating surfaces, thus allowing more time for the absorption of heat by the boiler surfaces. Therefore, the increase of economy must somewhat exceed the product resulting from multiplying the actual percentage of decrease of air used by the corresponding chimney losses.

This economic use of air is due to the method of operation peculiar to this stoker, in that it carries a bed of coal of unusual depth, the air being supplied from underneath, the volume of which, being under perfect control, and the continuous feeding action, completely overcoming the natural tendency of holes burning through the fire.

In point of construction, it is notable for the fact that no mechanical part of the stoker is subjected to heat. One of the chief objections found in all types of mechanical stokers has heretofore been that the mechanical parts were so subjected to heat as to render frequent repairs necssary, thus

is always the result of the incomplete combustion of hydro-carbons, whatever the fuel may be from which it has been distilled.

Smoke is a current of the gaseous products of combustion holding carbon in a very finely divided state in suspension. The intensity of the color is but an indication of the amount of carbon the smoke contains. In general, the process of smoke formation is this: The heat of the fire distills the hydro-carbons, and these in the presence of the air supply are broken up into their constituent elements, hydrogen and carbon. Hydrogen, the gaseous and more inflammable constituent, ignites readily; carbon, the solid constituent, requiring a white heat for ignition, passes off as soot.

If, on the contrary, the hydro-carbons with an admixture of air, pass through a white heat, the carbon cannot escape combustion, and thus the formation of smoke is made impossible. These conditions exist in the operation of this stoker. The hydro-carbons are liberated beneath the deep bed of incandescent coal, there in the presence of the air supply decompose, and the constituents mixed with the air, together pass through this bed of coal, the intense temperature of which is sufficient to thoroughly burn the liberated carbon. Thus theoretically and practically smoke-prevention is made a success.

The labor of the fireman is materially decreased, in that his duties are simply keeping the hopper filled and drawing the clinker at intervals of from six to twelve hours, depending upon the rate of firing and the grade of coal used. The clinker accumulating upon the dead plates on both sides of the furnace, presents no obstruction to the air supply, leaving the fire constantly in such a condition where at any

moment it may be forced, and thus be made to respond instantly to a sudden increased demand for steam.

The wide application of this stoker is no less a feature of interest. Not only has it been made a success under all types of steam boilers, but it is likewise equally well adapted and successful in puddling furnaces and heating furnaces, retorts and furnace work generally.

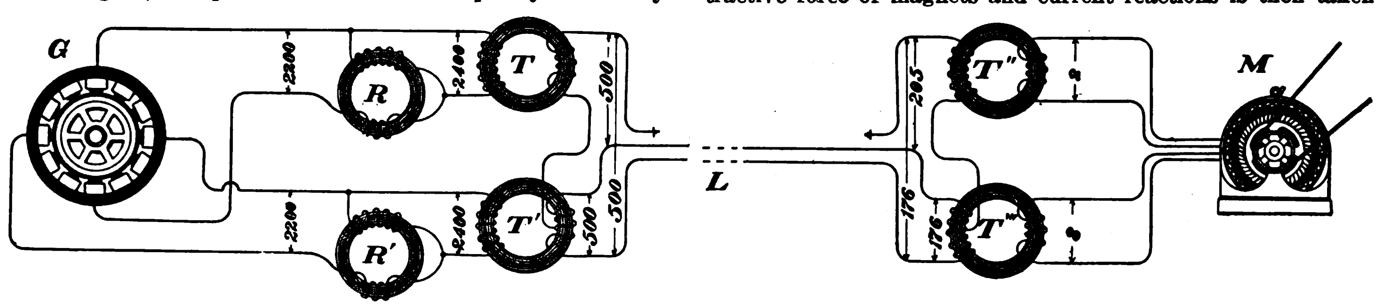
POWER TRANSMISSION.

THE NIAGARA-NEW YORK POWER TRANSMISSION AT THE ELECTRICAL EXPOSITION.

THE report of the nineteenth convention of the National Electric Light Association has just been issued by Secretary Geo. F. Porter, and presents a handsome appearance. Besides containing in full the papers read before the association at its last meeting in May, together with complete illustrations, it gives an excellent résumé of the salient features of the late Electrical Exposition, including the official reports of the companies engaged in the telephonic transmission of the roar of Niagara; of the companies over whose wires messages were sent around the earth; and the report of the transmission of power from Niagara to New York for the operation of the model of the great Niagara power plant. Among the latter is the report of Mr. L. B. Stillwell, electrical engineer and assistant manager of the Westinghouse Company, which contains some details of this remarkable work not heretofore published. Mr. Stillwell's report is given in abstract below:

The energy was transmitted by three-phase alternating currents: two of the conductors of the three-wire circuit were telegraph wires furnished by the Western Union Telegraph Company; the third was the earth, through ground connections in the power house at Niagara and in the Exposition building, New York City.

At Niagara, two-phase current at a frequency of twenty-five cycles per second and a potential approximating 2,200 volts was obtained from one of the 5,000 horse power generators of the Niagara Falls Power Company.



NIAGARA-NEW YORK POWER TRANSMISSION.

Two small transformers, connected in the manner devised by Mr. Chas. F. Scott, and first described by him in his paper read before the annual convention of the National Electric Light Association, in Washington, D. C., March 1, 1894, received the two-phase current and delivered to the transmitting circuits three-phase current. The potential delivered by these transformers, when supplied with a current at 2,200 volts, namely, 450 volts, was found to be rather low for good results, and the potential delivered to the line at Niagara was therefore increased to 500 volts by the use of two small transformers, connected as Stillwell regulators, in each side of the two-phase primary circuit.

The transformers at the New York end of the line were of the dimensions of the standard three-kilowatt Westinghouse transformer, but they were designed to deliver only fourteen watts each, and the energy required to magnetize the iron core was less than one and one-half watts. The energy lost in the copper, when the transformer was delivering fourteen watts, amounted to only one-quarter of one watt.

By actual test, the energy required to drive the motor was eight watts. The clearance between armature and field was one-fiftieth of an inch. No very accurate measurement of the power developed was taken, but when the line was in favorable condition, that is, when the weather was dry and the leakage consequently low, the power developed was probably about one-thirtieth of one horse power. The motor was of the induction type and wound for two-phase currents. The electrical specifications for this motor were made out by Mr. B. G. Lamme.

The specifications for the transformers were made out by Mr. J. B. Whitehead, under the immediate supervision of Mr. Chas. F. Scott, the electrician of the Westinghouse Company.

Referring to the diagram, G is the 5,000 horse-power, two-phase generator; R and R', the regulating transformers; T and T', the two-phase, three-phase transformers at Niagara; L, the line or transmitting circuit; T'' and T''' the three-phase, two-phase transformers in New York; and M, the motor.

The potentials given in the diagram are closely approximate for the Niagara end of the line; for the New York end of the line they roughly represent what may be called the average conditions of operation.

The potential of the currents delivered at the New York end of the line varied between rather wide limits, from one night to another, depending apparently to a very considerable extent upon the leakage from the line, as influenced by atmospheric conditions. The alternating-current motor was operated satisfactorily, potentials at the New York end of the line increasing when the motor was connected to the circuits. This effect was probably due to capacity of the circuits being counteracted by inductance when the motor and step-down transformers are connected; the current then more nearly coinciding in phase with the impressed electromotive force.

LITERATURE.

APPLIED MAGNETISM—By J. A. Kingdon. London, H. Alabaster, Gatehouse & Company; New York, D. Van Nostrand Company; 292 pp; 5½x8½. Price, $3.

It has been the author's object to avoid, as far as possible, mathematical formula, and though he has fairly well succeeded in this respect, it is evident that the subject in hand cannot be thoroughly handled without it. The book begins with a description of the general principles of magnetism, including magnetic flux, magnetic reluctance and permeability, etc., leading up to Hopkinson's law, and the calculations for leakage, etc., and this is followed by chapters on electromagnetic force and magnetomotive force of currents. The tractive force of magnets and current reactions is then taken up, and the experiments of Bosanquet, permeameter tests, etc., are given, in each case accompanied by actual examples worked out, showing the application of the formulae.

Under the head of qualitative magnetism the author discusses the various relations which exist between the direction of flux and the poles, between the exciting current and the magnet and its flux, and similar relations between current and magnetism. By rules and illustrations, these various relations are made plain. Under the head of "Alternators and Dynamos" the author treats respectively of the principles underlying the calculation of the principal elements of alternating and direct current machines, but as both are dynamos in the accepted sense of the term, it does not appear why the distinction in terms should have been made. Additional chapters of the book take up the subject of commutators and collectors, hysteresis and heating of armatures, alternating magnetic flux, under which heading the transformer receives brief treatment. Under "Electro-motors," the author, after a brief account of the underlying principles of their operation and construction, describes a number of practical applications to stationary power purposes, as well as to electric traction, and the propulsion of boats. Polyphase current also comes in for brief mention, and the book closes with two chapters on magnetic measurements and calculation in inch measurements.

We cannot say that the book is likely to prove of great value to the reader. In attempting to present the subject in a more or less elementary and popular style, something had, of necessity, to be sacrificed. We believe if the author had confined himself to either method of treatment of the subject, he might have rendered it more of a success than has fallen to his share in making a straddle.

CONTENTS.

INTERESTING TELEPHONE LITIGATION.

THE suit of the United States vs. the American Bell Telephone Company and Emile Berliner, for the cancellation of the Berliner patent No. 463,596, reached a hearing before the Supreme Court on Monday, November 9. On account of the importance of the case the hearing was extended from the customary four hours to nine. We call the attention of our readers to a summary of the arguments presented before the Supreme Court to be found on another page of this issue. It will be remembered that this famous suit was authorized by President Harrison, and was begun in February, 1893, by the Attorney General on behalf of the United States. Its object is to cancel the patent, for which application was made on June 4, 1877, by Emile Berliner, and which was issued after fourteen years of delay in the Patent Office, on November 17, 1891, to the American Bell Telephone Company, assignee. The patent is understood to cover the mode of operation and apparatus of the microphone, or battery transmitter, that is, all known forms of transmitters which are adopted for commercial use. Under its protection it appears that the American Bell Telephone Company may continue its monopoly of the telephone business until the year 1908.

The suit was brought in the Circuit Court, District of Massachusetts, and on January 3, 1895, Judge Carpenter decided in favor of the United States and ordered the patent canceled. The American Bell Telephone Company brought the case on appeal to the Circuit Court of Appeals, District of Massachusetts, and won the decision, Judge Carpenter being overruled by Judges Putnum, Colt and Nelson. The United States then appealed the case to the Supreme Court. An early decision is expected by both sides, and anxiously awaited by the public.

We also make note in this issue of the victory just won by the opposition telephone interests in having the Watson switch patent set aside. Those who chose to fight this instead of "knuckling down," are certainly entitled to great credit for exposing the invalidity of a patent which has popularly been assumed to have great merits as a Bell bulwark. As a matter of fact, the resort to the Carty bridging bell method has shown the Watson hook and induction coil circuit not to be so vital and essential as it was assumed to be; but independent manufacturers did not wish in avoiding Watson to come into collision with Carty, and thus more or less of an actual blockade ensued. The present situation is that another of the barriers against free telephonic work has been removed, and to that extent the independent manufacturers and exchanges are benefitted, and the public as well, by the opportunity for greater competition.

The Watson switch patent, No. 270,522, now invalidated, has eight claims, but the pith lies in the first two here quoted:

1. In combination with suitable contact-points and springs electrically connected with the call-circuit and the primary and secondary circuits of the transmitter, the latter circuit, including the hand telephone, a lever electrically connected with the main line in a telephone circuit, substantially as described, to bring in the hand telephone and transmitter and break the call circuit, or to cut out the hand telephone and transmitter and establish the call circuit, accordingly as the lever is moved in one direction or the other.

2. In combination with suitable contact points and springs electrically connected with the call circuit and the primary and secondary circuits of a transmitter, the latter, including a hand telephone, a lever electrically connected with the main line and provided with a hook to support the hand telephone, and a spring tending to overcome the weight of the hand telephone, substantially as described, to bring in the hand telephone and transmitter and break the call circuit, or to cut out the hand telephone and transmitter and establish the call circuit, accordingly as the hand telephone is removed from or hung upon said hook.

THE DECADENCE OF THE MANHATTAN ELEVATED.

THE annual report of the Manhattan Elevated Railroad, just issued, would indicate that the patronage of the road was going from bad to worse, and that the long period of inactivity and conservatism in the management of the system was fast bringing it to ruin. This is a matter of deep regret, for it affects New Yorkers vitally and makes them bitter, although they have no natural ill will towards the company. The falling off is attributed to the competition of the Metropolitan Traction Company, but this is hardly true, as that would have been found to be a means of actually increasing the traffic had the elevated responded to competition with a brisker, brighter, better service. To show what the elevated has been losing, we give below a statement of comparisons for the last five years, each year ending September 30:

Year.	Gross.	Net.	Passengers.
1896	$9,352,115	$3,224,786	183,437,244
1895	9,745,927	3,613,100	188,072,645
1894	10,138,143	4,042,586	196,159,323
1893	11,137,051	4,926,891	219,621,017
1892	10,908,579	4,943,690	215,122,575

It will be seen that in these five years the elevated road has lost progressively, until this year the number of passengers is 36,000,000 less than in 1892, or, say, 100,000 a day. Yet the city has, meantime, increased vastly in area, wealth, in population, and in that diversity of interests, amusements and functions which does so much to foster travel. Why, then, should the service have failed to secure as large a patronage unless it is falling below its opportunities and its responsibilities?

It is known that the elevated is now "experimenting" with electricity and compressed air, but why it should have to "experiment with electricity" at this late day is a deep mystery and a marvel. Of course, there are conditions and difficulties peculiar to the work, but they could have been met long, long ago, had the company chosen to do a little for itself instead of throwing all the cost of preliminary work upon the people desirous of getting its contract. To-day we have successful elevated electric roads in Liverpool, Chicago and elsewhere; successful underground electric roads in London and Buda Pest; some 1,500 electric trolley city and long distance roads all over the world, carrying annually far more than the population of the globe, and yet the cautious, fossilized management of the elevated keeps on prating about the dubious nature of electric traction!

Some estimable gentlemen have just been elected to the elevated directorate, but as they are Gould-Sage men, and as that means a continuance of the old regime of poor service, timid inactivity and declining revenues, we fear New York cannot expect much improvement in that quarter. It is preferable to travel in the open air, but the necessity for the proposed underground electric road is daily rendered more obvious through the policy of those who should render its construction superfluous by their efficient provision for business waiting to come to them.

THE AMERICAN BELL-WESTERN UNION AGREEMENT.

IT is only to be expected that the present relations of the Western Union and American Bell Companies should remain the subject of a good deal of curiosity. The old agreement, whose terms have appeared in full only in these pages, has not been succeeded by another, if we are to believe the statements of parties directly interested; yet where two lines of industry are so closely related as are the telegraph and telephone, there must be some kind of understanding in the very nature of things. The old agreement arose out of a perception of that fact, and the Western Union Company only abstained from telephonic work upon the easy terms of receiving a large sum of money to sit still, while the telephone companies were to leave its field undisturbed. The payments to the Western Union by the American Bell up to date have probably reached $8,000,000, and have run up to $690,000 a year. This money the Western Union stockholders lose, and it now goes into Bell stockholders' pockets, to that extent materially swelling the one dividend, while reducing the other. It is obvious that the Western Union would like to find a source of income that would yield a like amount, and this it might obtain from a telephonic business of its own, such as it had in the old days prior to the agreement; but this would simply invite sharper competition from the Bell telephone service, and meantime the Berliner patent has not been thrown open, so that an element of uncertainty awaits any such investment just now. Besides, the Postal Company could readily effect an operating alliance with the Bell interests, and it has even been intimated that "Barkis is willin'." It would be pretty hard for the Western Union to make ends meet under those competitive conditions.

After all is said, there remains the fact that such large interests and such large masses of capital do not fight when there is a better way out. Both parties may agree, or may have agreed already, to keep within their familiar fields for a further term of years.

NIAGARA TO BUFFALO.

DURING the present week, indeed, even before these lines have been published, it is expected that the Niagara current will be delivered in Buffalo for regular consumption, over the circuits of which we gave some interesting views and data a few weeks ago. Pending the delivery of current in Buffalo, a great many uses of it have been developed around the falls, but it is the transmission to Buffalo that has chiefly engaged the thoughts and fancies of the public, and has, in reality been the goal of the courageous men to whom the great undertaking is due. Congratulations are certainly in order, not only to those engaged in the enterprise, but to Buffalo, whose future is brighter than that of almost any other city in the Union. It is true that we are still at the beginning of the utilization of Niagara, but a very definite and hopeful beginning has been made.

MOTORCYCLES.

WHILE the motorcycle industry in this country does not yet betray any great signs of activity, Europe is witnessing a brisk development. Even if we discount a great deal of the newspaper talk, enough fact remains to show that the art, still so young, has taken firm foothold. The parade of horseless vehicles in the Lord Mayor's show in London, for the first time, was a notable event, and it has now been succeeded by a highly interesting race from London to Brighton, in which an American vehicle won. In France similar activity prevails. Mr. Ingersoll, editor of the "Horseless Age," informs us that the European investment in motorcycle building already reaches $10,000,000, and that many of the new factories are hardly yet in full production, so that the number of such vehicles in use is not a criterion of the number that will be seen next year.

It is worthy of note that the Duryea motor winning in England was easily beaten by two electric vehicles at the recent Providence races, where the distances were short. As a long distance vehicle it has evidently various recommendations, and in the smooth roads of England it has found favorable conditions denied it on the usually execrable mudways that, under the name of thoroughfares, encircle most American cities just beyond the city limits. Even in the cities our streets need great improvement in paving before the motorcycles, electric or any other, can do their best. The statement in the newspapers last week that the mails in New York City are to be handled largely by horseless wagons is slightly anticipatory, for although one of the papers has illustrated the wagon, we learn that there is still indecision as to their nature and as to their motive power. But they will come presently, and with them better streets.

TELEPHONY AND TELEGRAPHY.

THE BERLINER MICROPHONE PATENT BEFORE THE U. S. SUPREME COURT.

IMPORTANT ARGUMENTS ON BOTH SIDES.

THE suit of the United States vs. the American Bell Telephone Company, et al., for the cancellation of the Berliner patent, No. 463,569, owned by the American Bell Telephone Company came up on Monday, November 9, before the United States Supreme Court. The argument was opened for the United States by Judge Taylor, who dwelt on the following points in detail:

First—The long delay of the application in the patent office.

Second—The relation of the Berliner patent of 1880 to the Berliner patent in suit.

In reference to the delay in the office, it was shown that on June 7, 1877, Emile Berliner filed an application, which, in 1878, came into the possession of the American Bell Telephone Company, and after various amendments and interferences, and after over fourteen years of delay in the patent office, was finally issued on November 17, 1891, to the American Bell Telephone Company, as assignee.

On June 9, 1882, the patent office notified the American Bell Telephone Company that "as at present advised, it is believed that the claims presented may be allowed, but final action in this case must be suspended in view of probable interferences with other pending applications, which will be declared as soon as practicable."

The "probable interference" which was to cause the delay was on the application of Drawbaugh, of July 26, 1880. This application claimed the magneto transmitter and receiver of Bell and the carbon transmitter of Edison. The patent office immediately rejected Drawbaugh's claims, on account of the undisputed and inconfutable evidence of more than two years' prior use of the inventions claimed. Drawbaugh filed an affidavit in which he did not pretend to deny the fact of prior public use, on which the rejection of his claims rested. The patent office should then have passed Berliner's application to issue. However, as President Hudson, of the American Bell Telephone Company, testified, "by common consent" the patent was withheld to await the decision of the Court in reference to Drawbaugh's pretensions as an inventor, not in reference to the prior public use. The evidence in this suit was completed in June, 1884. Judge Wallace handed down a decision in December, 1884, and another in December, 1885, after additional evidence for Drawbaugh had been submitted, both decisions declaring Prof. Bell the true inventor; and finally the Supreme Court in March, 1888, again decided in favor of the Bell Company.

It was the duty of the Bell Company, knowing the impossibility of an interference with Drawbaugh, on account of the prior use of the invention, and previous to the above dates, to demand action on the part of the patent office. It was the duty of the Bell company, after each of the above decisions, declaring Drawbaugh without grounds for his claims as a prior inventor, and their duty each day after the Supreme Court declared his claims void, to demand action from the patent office on the Berliner patent. They did not do so. On the other hand, it was the duty of the patent office to have passed Berliner's application to issue after the rejection of Drawbaugh's claims on account of prior use. It was again the duty of the office to pass it to issue after each of the above dates, when it was seen that Drawbaugh had no rights as a prior inventor.

Instead of so doing, it delayed action until after the decision of the Supreme Court, and then forced Drawbaugh, against his protest, to submit testimony in reference to the prior use upon which his claims had been rejected eight years previously, and concerning which there was no bearing on the issue of the Berliner patent, for Drawbaugh had now no status as a prior inventor. Finally, after more than three years, the Commissioner wrote, on October 29, 1891:

"As this applicant (Berliner) has technically perfected his rights to the allowance of a patent, I think the allowance should issue, largely because well settled principles of public policy forbid us to give any further opportunities for holding this application in the office." On November, 17, the same year, the patent issued.

In rebuttal, Mr. F. P. Fish, of Boston, and Joseph H. Choate, of New York, argued for the American Bell Telephone Company, that strenuous efforts had been made to secure the issue of the patent; that the Bell company had received the patent under the rules of the patent office, and that whatever delays there may have been were due to the patent office and not to the Bell Company, and the defendants should not be held responsible for such delays. Also, that the Bell Company were under no greater obligations than any other applicant to hasten the action of the patent office, and, furthermore, that the delay was not without precedent.

On the other hand, Mr. Causten Browne, on behalf of the Government, argued that, as the duty of the Commissioner was only to issue such patents as did not conflict with the rights of the public, there did exist in this case an extraordinary duty on the part of the company to speed the application by every means known to law, and if it failed to do so, that failure was sufficient grounds for the cancellation of the patent.

The second point argued by Judge Taylor, on the part of the United States, was the double patenting of the invention in question, on account of the patent issued to the same inventor, Berliner, in 1880. The Bell company argue that Berliner's 1880 patent, while covering the identical apparatus of the patent in suit, yet was to be used for an entirely different purpose and operated in an entirely distinct manner, that is, it was a patent for a receiver, while the patent in suit was for a transmitter. The Government, on the other hand, shows that the fourth claim of the 1880 patent was a claim for the identical apparatus of the patent in suit, used as a transmitter and receiver, in combination. Therefore, as this combination of the transmitter and receiver of the fourth claim of the 1880 patent cannot be used without infringing the 1891 patent, there exists a case of double patenting of the transmitter by the same inventor, and the latter patent (the patent in suit) is void under the ruling in the Miller vs. Eagle Manufacturing Company case, 151 U. S.

In addition to these two points argued by the United States, which were the grounds upon which Judge Carpenter adjudged in favor of the United States, in the Circuit Court, District of Massachusetts, on January 3, 1895, and whose decision was overruled by the Circuit Court of Appeals, on the ground of lack of jurisdiction in the absence of fraud, Judge Aldrich, representing the United States as special assistant counsel, argued the following points, set up by the United States, urging the cancellation of the patent: "Berliner's patent, No. 463,569, is invalid and should be cancelled, because the application as filed June 4, 1877, did not describe the constant-contact transmitter which is covered by the patent."

Judge Aldrich argued as follows: I. The history of the application above shows that all the examiners in the patent office, six in number, who actually passed upon the merits of the question from the year 1880 to the issue of the patent, in 1891, found and determined that the application as filed June 4, 1877, did not contain a description of the constant-contact transmitter of the patent.

Berliner stated in his application, as filed June 4, 1877, in reference to those instruments which might operate by constant contact:

"These simple instruments will reproduce any musical sound uttered in the neighborhood of one of them; but for the reproduction of special sound, such as speech, they are not adapted."

Berliner then describes a double pin transmitter, which is necessarily a make and break transmitter, and claims the transmission of speech by this instrument. Examiners Freeman and Lyons said in reference to this instrument, and in an official communication from the patent office:

"This is the only form of instrument which applicant describes as adapted to the reproduction of other than purely musical sounds." And again: "That the invention disclosed in this case is not a speaking telephone, has been conclusively shown in this answer." The invention spoken of was the single pin transmitter, which the Bell Company claim Berliner meant to describe as adapted for the transmission of speech. The American Bell Telephone Company also argued that, even if the application as filed by Berliner did not contain the constant-contact invention, yet the application as amended in 1877 did contain it, and, therefore, the validity of the patent cannot be assailed.

Judge Aldrich argued that the application as amended in 1877 did not contain the constant-contact transmitter, but that this device was inserted in the subsequent amendments made by the Bell company, the entire specifications and drawings having twice been erased and new ones substituted, but that even if the application as amended in 1877, did contain the invention in issue, yet the patent is void, for Berliner failed to execute and file the oath of the amendments until May 27, 1882, nearly four years after the invention sworn to had gone into commercial use.

2. "The Berliner patent is void, because of irregularities of

procedure in the patent office, aside from questions of delay and insertion of new matter."

Judge Aldrivh showed that the Bell company appealed from the decision of the examiners to the effect that the amendments contained "new matter," directly to the Commissioner, instead of first carrying the appeal to the Board of Examiners-in-chief, as the law requires. The Commissioner decided that the amendments contained no new matter.

The Bell company argued that the Commissioner had final jurisdiction, and the decision would ultimately have been in their favor, even if it had first gone through the Board of Examiners-in-Chief. Judge Aldrich argued that the statutes required the appeal to be carried through the Board of Examiners-in-Chief, and it by no means follows that the Commissioner would have been uninfluenced by the opinion of a board composed, as required, by statute, of "persons of competent legal knowledge and scientific ability."

3. "The Berliner patent is void, because the process and apparatus therein claimed were described by Alexander Graham Bell in his patent, No. 174,465, of March 7, 1876, and were a part of Bell's invention disclosed in that patent." This fundamental telephone patent of Bell's claimed, in addition to the method and apparatus of the magneto telephone, the method of the microphone, or constant-contact battery transmitter. Bell did not claim the apparatus of the microphone, but in May, 1876, he for the first time, successfully transmitted speech and used for the transmitter a constant-contact battery transmitter, or microphone—that is, his liquid transmitter. The testimony of the American Bell Telephone Company in the previous "telephone cases" showed that this liquid transmitter of Bell's was, contrary to the popular opinion, very different from the Gray liquid transmitter, and was in fact, a true microphone, with a surface contact, the variation in resistance being "at the contact of the rod and the liquid." Now, it was known that the resistance of a given contact can only be changed by a variation in the number of molecules in contact at the variable resistance point; in other words, the variation of resistance depends wholly on the variation in area of contact. This was as true of Berliner's microphone as of Bell's. A variation in pressure between the electrodes was as necessary an adjunct in the Bell transmitter as it was in the Berliner. The Bell company claimed that Berliner's microphone operates by a variation in pressure causing a variation in the "intimacy of contact" of the electrodes, while the Bell transmitter depends upon a variation in the "area" of contact. Judge Aldrich argued that a variation in intimacy of contact could only produce a variation in resistance by a variation in the number of conducting molecules, which is a variation in the area of contact. Also, that the Bell transmitter, in addition to its operation by a change in superficial area alone, also operates by means of a variation in intimacy of contact, due to a variation in pressure between the electrodes in constant contact. Therefore, Judge Aldrich argued that the method of the Berliner patent, that is, Claim 1, "the method of producing in a circuit electrical undulations similar in form to sound waves by causing the sound waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described," is identical with the method of the Bell patent and apparatus.

Though Bell failed to patent the apparatus of his method, no subsequent inventor was entitled to a patent on his apparatus or method. Bell successfully transmitted speech by the variable resistance method in May, 1876; Berliner's earliest date of record is January, 1877. Thus, Judge Aldrich argued: "When an art has been covered by a process patent, as the art of telephony by the patent to Alexander Graham Bell, of March 7, 1876, no other process patent can be sustained in the same art, unless the result is accomplished by the application of a new principle. . . . At the most, Mr. Berliner would be entitled to a patent for the very structure claimed by him, which would be valueless, as the Edison and Blake microphones are now public property."

In conclusion, Judge Aldrich called attention to the companions of the Berliner patent in its long sleep in the patent office, that is, the Edison carbon patents which actually expired by English limitation before their issue in this country. These patents claimed broadly the use of carbon for telephone transmitters. The efforts made by the Bell Company to sustain these patents by changing the interpretation of the Revised Statutes, Section 4887, would be recalled by the Supreme Court Decision in the Bate Refrigerator case, upholding this section.

Following the argument of Government counsel, Messrs. McNaught and Redding, representing the Standard Telephone Company, of New York, submitted briefs on the same side of the question. The points argued by them were the following:

1. Mode of operation is not a patentable novelty.
2. The Bell patent of March 6, 1876, covers and discloses the entire art or method, including mode of operation for transmitting speech by means of electrical undulations.
3. The Berliner patent of 1891 is void for the reason that patents covering the same invention were issued in Russia, Italy, Great Britain, Canada, and many other foreign countries to Berliner, Edison and Blake, and these patents had expired in most of those foreign countries before the Berliner patent of 1891 was issued.

Berliner, in his specification filed in the patent office September 1, 1880, said: "The essential part of the apparatus is the point of contact."

Messrs. McNaught and Redding, in their brief, concede the correctness of Berliner's specifications in this particular, and they demonstrate in their brief that the Berliner novelty is in applying Bell's mode of transmitting speech by electrical undulations and his adjustment of the contact between electrodes as described in his patent of March 6, 1876, to Regnault's and Reis's old telephonic apparatuses.

The American Bell Telephone Company's counsel contend that the apparatus described in the Berliner patents of 1880 and 1891 is exactly like the old Regnault and Reis apparatus, and that Berliner's apparatus produced speech while the Regnault and Reis apparatus would not talk.

When the different parts of two machines which are exactly alike are put together and one operates and the other will not, there is something wrong with the one that will not operate. In the old Regnault and Reis structures there were diaphragms and electrodes exactly like those found in the Berliner apparatus; yet the latter talked and the former would not. The reason why one operated and the other would not was not because the parts of the machine were different, but because they were put together differently; and that difference is confined entirely to the point of contact. This, Mr. Berliner says in his specifications, is the essential part of his apparatus. Berliner's novelty, if any, was in applying Bell's adjustment and undulatory currents to the Regnault and Reis ancient apparatus. He simply put together Regnault's and Reis's solid electrodes in the way pointed out in Bell's patent of 1876 so as to prevent a make and break in the circuit.

The Bell Company, in paragraph 7 of its answer in the case now pending before the Supreme Court, avers that this adjustment of pressure between the electrodes is mechanical. Its counsel, in their briefs filed in the case, argue that the principles are not mechanical but electrical. The same counsel, in the trial of the Bell Telephone Cases reported in 126 U. S., at page 278, stated that the principles employed were mechanical and not electrical. The Bell Company's principal expert, Prof. Cross, in his testimony in the case now pending before the Supreme Court, said that the principles employed in the adjustment of pressure were mechanical.

The third point made by Messrs. McNaught and Redding in their brief, was fully discussed in our issues of January 17, 24 and 31, and of February 7, 14, 1894. It was shown that Berliner, Edison and Blake had taken out patents in England and other foreign countries, and that these patents had expired before the Berliner patent of 1891 was issued. At that time the Supreme Court of the United States had not rendered its opinion in the celebrated Bate Refrigerating Company case.

The Edison patents, Nos. 474,230, 474,231 and 474,232, which fully cover and disclose the Edison microphone, are printed in full in the record in the case now pending, and the record shows that they were patented in England as No. 2,909, July 30, 1877, and expired July 30, 1891, or three and a half months before the Berliner patent involved in the present suit was issued.

In reply to the arguments of Messrs. McNaught and Redding, the Bell Company's counsel contended that they could not be made for the first time in the Supreme Court of the United States as they had not been previously brought up in the U. S. Circuit Court and the Court of Appeals.

PROS AND CONS OF TELEPHONE COMPETITION.

REFERRING to the excellent briefs in Saturday's "Evening Post" of the arguments to be heard in the telephone suit this week, is the statement in the third paragraph true that the Berliner and the Edison "are the only patents which stand in the way of the use of the microphone transmitter in good and practical forms?" If that statement is true, then we who are using similar transmitters not supplied by the Bell Company are liable to be called on for explanations and an accounting, if the United States does not win the suit. In

fact, are we not present transgressors and liable at any moment to be involved in litigation?

For two reasons I seriously doubt the correctness of the statement. First, because the company from whom we purchased our telephones gave up a written guarantee that there was no infringement, and also agreed to protect us from all expense should litigation for infringement of patents follow the establishment of our exchange. And (second) because ex-Solicitor-General Aldrich, in interviews as reported by representatives of the press in your city, in the spring of 1895, stated that the opposition telephone company with which he was connected owned or controlled patents that would give that company a more exclusive monopoly of the telephone business than the Bell enjoys. And it was principally on this statement that we invested our money in a telephone exchange.

It is doubtful if many of your readers realize how large an investment will be practically wiped out if the United States fails to win this suit. For during the past two years opposition telephone exchanges have been established—representing an investment of several millions—in more than 100 towns or cities. In many of these exchanges the mere closing of the plant in compliance with the decree of the court will not end the liability of the stockholder, and his only loss prove to be the amount originally invested, for many of these exchanges are not yet in operation, have no income, and have a large indebtedness to meet. Take Jersey City, for instance, or Newark, where the public-spirited citizens have already probably invested more than $100,000 in the stock of the local company, and yet the work of construction has hardly begun. And while a few telephones are connected in service, yet the agreement is that until (500?) a stated number are operating satisfactorily, no rental will be collected, and hence it is now all outgo and no income, and must so continue for some weeks.

Elizabeth and Trenton have opposition exchanges, and Montclair, Paterson, Cranford, and other towns are trying to get under way.

GEORGE SLAXZON.

Jersey City, November 9.

The statement made by Mr. Slaxzon in his letter on the telephone question is really most amusing. Would he have your readers infer that the United States Government has employed ex-Solicitor-General Aldrich for no other purpose than to destroy one monopoly that another may thrive? Yet that is the natural and the only inference we can draw if Mr. Aldrich's company really owns or controls "patents that would give that company a more exclusive monopoly of the telephone business than the Bell enjoys." I do not believe the United States officials are engaged in that kind of a scheme, while I do believe that if the Berliner and Edison patents are declared invalid it will not materially change the present policy of the Bell companies. But the cancellation of the patents will afford an excellent opportunity for adventurers to inveigh unsuspecting and inexperienced investors into attempting to establish competing telephone exchanges in our larger cities, where, in the very nature of the service, the telephone exchange must ever remain a natural monopoly, and two or more exchanges prove a burden that the progressive merchants must endure and support. We now have two telephone companies in Trenton, and a third is getting under way.

When a new telephone company attempts to secure a foothold in a large city, it finds that one of the great problems it must solve lies, not in the total number of subscribers it can secure, but in the number of desirable subscribers that will prove permanent and paying patrons. For the service of a telephone exchange increases in value in the same ratio as the names of the desirable elements in the community are added to its list of subscribers. In other words, while a newspaper circulating only among saloons and read principally by the frequenters of such places might prove profitable to a certain class of advertisers, the general advertiser would not use its columns, as it would not reach the public in general—the buying classes. So a telephone exchange might secure several hundred or a thousand or two subscribers, and yet the combinations afforded have no practical value to the constant user of telephone service or the general public, and the secured subscribers be rarely called for. But the progressive merchant must pay his tribute to each company just the same. Thus it is not only the greatest number of people you can reach with the aid of the telephone, but the greatest number of the very people you desire to reach that renders telephone service invaluable.

A second problem, and one not so difficult of solution as that of securing the necessary desirable subscribers, is to secure the capital necessary to construct a modern telephone plant. Such a plant cannot be properly constructed for less than from $95 a subscriber to $175 a subscriber, depending on the size of the exchange; the larger the plant the higher the average cost per subscriber. A first-class telephone plant having a switchboard capacity of 1,000 subscribers can be completed for $125,000, while it would probably require an investment of $500,000 to complete every detail in a modern plant of 3,000 subscribers. Many opposition telephone exchanges have been built for a less sum per subscriber, notably Topeka, Kan.; Fort Smith, Ark.; Selma, Ala.; Waukesha, Wis.; and some twenty others. But these exchanges no longer exist, having gone the way of all purely speculative enterprises and leaving no return for the heavy investment. Now the shrewd financier is not putting his money into investments that promise as fat pluckings for promoter and lawyer as competing telephone exchanges do. He may loan the use of his name in return for a profitable consideration. But the plant will be built (well or poorly) from the investments made by "lambs"—honest and unsuspecting creatures who are so inexperienced as to believe that because a certain prominent citizen holds quite a block of stock in a new enterprise he must have invested a large amount therein. And as the "lamb" seldom has the reserve capital necessary to protect an investment of this character, he soon has a practical illustration of how easily his venture may be swallowed up and lost for ever.

But the most difficult problem that confronts the new company in a large city is to so plan the constructive and engineering features of a plant as to insure from the start a satisfactory high-class service to subscribers already educated to a high standard of telephone service. It means something more than placing a switchboard in a room and connecting thereto the wires radiating out to the subscribers' telephones. For the building of the modern telephone plant in a large city includes the planning or the construction of outlying exchanges connected to each other and also to the main exchange by underground trunk lines; and in the proper arrangement and disposition of these trunk lines, and the rapid handling of the ever-increasing traffic in conversations, abides an engineering problem, requiring capacity, ability and experience of the highest order to satisfactorily solve and thereby evolve a successful modern telephone plant.

JOHN WALTON BOURKE.

Trenton, N. J., November 11.

THE PACIFIC CABLE COMMISSION.

In pursuance of the summons issued last month, the Pacific Cable Commission met at the Colonial Office, in London, on November 9. The meeting was presided over by Lord Selborne, and was attended by the Canadian representatives to the conference, Sir Donald A. Smith and Mr. Jones. Sir Saul Samuel, Agent General in England for New South Wales; the Hon. Duncan Gillies, Agent General in London for Victoria, and Mr. George H. Murray, one of the principal clerks in the Treasury, were also present.

The meeting was merely for the purpose of organization. Secretary Mercer has arranged the lines of business to be pursued by the commission. It was announced that the commission would hold frequent meetings and make its report at the end of the year.

LETTERS TO THE EDITOR.

WATSON PATENT EXPIRED.

In the United States Circuit Court here to-day a motion was made by the attorneys, R. H. Parkman and S. S. Stout, of the Western Telephone Construction Company, to the effect that the Watson patent, No. 270,522, owned by the Bell Company, and covering all forms of telephone hook switches, had expired on July 30, 1895, by virtue of the expiration of a Canadian patent to Watson covering identically the same invention; an order was entered accordingly.

The discovery of this patent will be a great surprise to the electrical fraternity in general, and has killed one of the greatest bugbears with which competing telephone concerns have had to cope.

The Western Telephone Construction Co. were put to great expense to defeat this patent, and their efforts will not only secure them and their customers against interference from it, but open up the use of the telephone hook switch to the public. The immediate dismissal of suits brought against others will probably result. Another good Bell patent gone!

JAMES E. KEELYN,

President Western Telephone Construction Company.

Chicago, November 7, 1896.

THE TELEGRAPH IN ABYSSINIA.—**A Brussels firm is about to equip Abyssinia with a telegraph system, the more important stations to be connected with the imperial residence. Menelek proposes to be an up-to-date monarch.**

Electric Lighting.

A SINGLE COMMUTATOR THREE-WIRE GENERATOR.

AMONG the numerous excellent exhibits of dynamo electric machinery recently shown at the Berlin Industrial Exhibition is a machine built by the Electricitäts Actien Gesellschaft, formerly W. Lahmeyer & Company. This machine is remarkable in that it is designed to furnish current for a three-wire system of conductors, with a single armature, and commutator. In outward appearance the machine differs very little

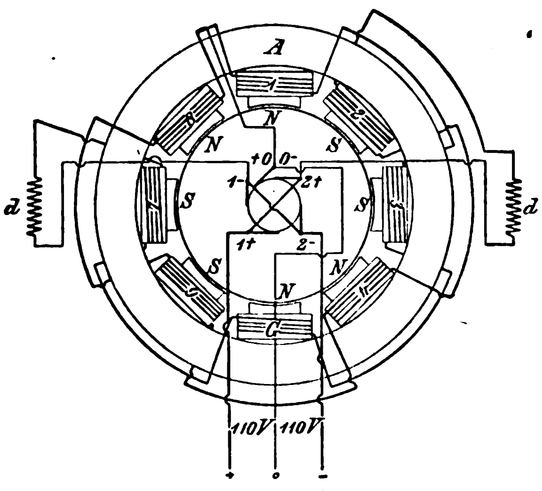

FIG. 1.—LAHMEYER DYNAMO FOR 3-WIRE CIRCUITS.

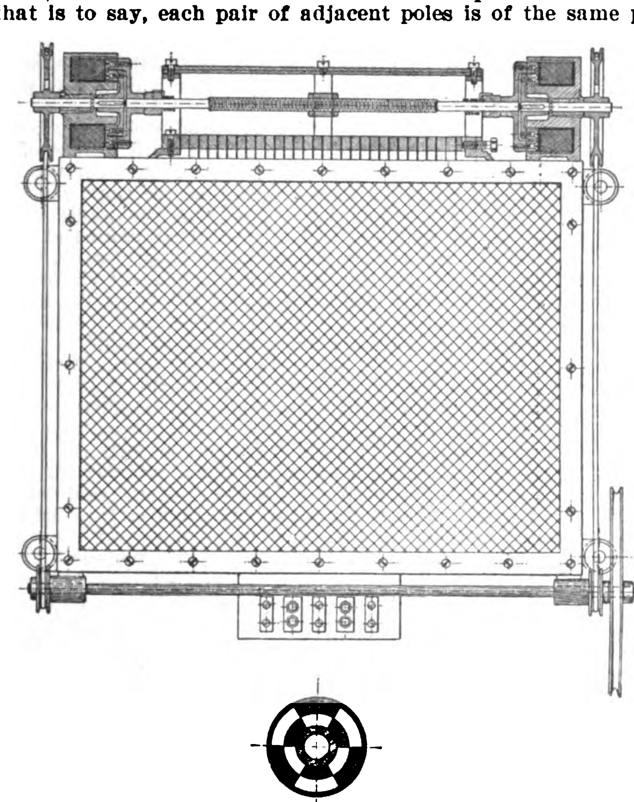
from the ordinary multipolar type, but the arrangement of its circuits is of considerable interest.

As shown in the accompanying engraving, Fig. 1, for which we are indebted to the "Elektrot. Ztsch.," the machine has eight poles, which are so wound that four double poles are created; that is to say, each pair of adjacent poles is of the same polarity. Within this field revolves a simple drum armature, wound for four poles. The four brushes, connected in pairs, 1—, 2—, and 1+, 2+, take off current at 220 volts, and a fifth brush bears between the brushes, 1— and 2+. This brush serves the purpose of dividing the potential, and in its relation to the other pair of brushes has a potential equal to zero.



FIGS. 2. AND 3. -LAHMEYER AUTOMATIC RHEOSTAT.

The magnet spools are excited in groups of four in series at 110 volts; that is to say, poles 1, 3, 5 and 7, and 2, 4, 6 and 8 are in series, respectively. Those magnet coils that excite the branch +0 are connected to the binding posts of the branch, and vice versa, so that the two branches excite each other mutually, by which means a better regulation is effected. Each branch can be regulated independently of the other, and the difference in load of the two sides of the three-wire system may be quite considerable.

The total weight of the machine is 7,500 kilogrammes, of which 1,900 are due to the magnetic system, 450 kilogrammes to the armature core and 450 kilogrammes to the winding.

The regulation of the machine is effected by two automatic rheostats operated by a small electric motor. This automatic regulator is of the usual type of sliding contact, operated by screw and nut, but instead of employing conical friction wheels as heretofore, the motion is transmitted from the driving spindle to the contact-shifting spindle by means of a pair of magnetic clutches, as illustrated in Fig. 2. The spindles passing through each bell magnet, are each constantly driven in opposite directions by cords from the main driving pulley. Between the inner and the outer wall of the bell magnet there are three inner and three outer segments of iron, shown in Fig. 3. The inner segments are connected with a short spindle, which is constantly driven, whereas the outer segments are connected with the spindle which operates the sliding contact. It thus follows that when the bell magnet is excited its inner segments carry the outer ones along with them, thus shifting the rheostat contact. As the two magnetic spindles are driven in opposite directions, it follows that, depending upon which magnet is excited, the contact will be shifted one way or the other. The magnets are thrown into circuit by means of a contact voltmeter.

AN OHIO TOWN IN BUSINESS.

A dispatch from Springfield, Ohio, of November 9 says: "Bellefontaine, the local option town near here, which recently was compelled to let its police force go, owing to no funds, is now on the eve of having its light supply cut off. The electric light trustees have appealed to the Council for aid, stating that they must have at least $3,000 immediately or shut up the light plant. The trustees are so badly in debt now for fuel, etc., that they decline to take any further risk. In the meantime, the wrangle between the wets and drys goes on. The bitterest feeling prevails.

A CITY LIGHTING SCHEME FOR NEWARK, N. J.

Newark may soon strive to own an electric lighting plant. The question is now under consideration. It was first brought up by the suggestion that the city establish a lighting system for the Centre Market. It was shown that the cost of a dynamo and plant for the purpose would be an economy compared with the prices charged for lighting by the private corporations. Then it was urged that the city take charge of its own lighting. In 1893 it cost the city $164,000 and in 1895 $194,000. It is said that the cost this year will exceed $200,000. Experts say that if Newark owned the plant the cost would be reduced one-half, and the remainder could be used as interest on bonds and for a sinking fund for the principal of the debt to be incurred in the establishment of the municipal lighting system. The matter will be brought before the common Council, and it is expected that there will be vigorous opposition from the friends of private ownership of public necessities.

SALE OF JACKSONVILLE ELECTRIC LIGHT CO.'S PLANT.

The plant of the Jacksonville Electric Light Company has been sold at legal sale to Arthur T. Parker and H. C. Bullard, for themselves and as trustees, for $5,000.

This was the only bid received. The decree under which the sale was made required that all bidders make a deposit of $1,000 before bidding on the property, and that no bid should be taken for less than $5,000.

The bid was made by Arthur G. Hamlin, attorney for the purchasers, and there being no further bids, H. H. Buckman, special master, knocked down the property, which consists of the engines, boilers, dynamos, poles, wires, etc., to Mr. Hamlin, as attorney.

EBENSBURG, PA.—The Ebensburg Light and Power Company reports that it is in the market for a 100 horse-power boiler and an 800-light alternator.

ROENTGEN RAYS.

RECENT ROENTGEN RAY OBSERVATIONS.

BY THOMAS A. EDISON

THE following is a list of chemical crystals fluorescing to the Röntgen ray, in addition to the seventy-two already published by me[1]. The experiments covey every chemical substance sold commercially. Attention is called to the fact that the double salt of silver and sodium chloride fluoresces. Small quantities of this salt occur in dry plates. It is probable that the sensitiveness could be greatly increased by definite amounts being added: Diphenylamine sulphate; sodium anthranilate; uranium borate; silver and sodium chloride; platinum and ammonium cyanide; gold and sodium cyanide; platinum and potassium lithium cyanide; platinum and strontium cyanide; sodium naphthylamine sulphonate; uranium and calcium phosphate; zinc and potassium cyanide; zinc and copper cyanide; uranium oxychloride; platinum and calcium cyanide; platinum and cerium cyanide; platinum and potassium sodium cyanide; lead sulphocarbolate; ammonium mellitate; lead sulphocyanate; calcium silico fluoride; sodium sulphamilate; sodium sulpho carbolate; mercury urate; para quinoline sulphonic acid; caffein hydrochlorate; sodium para cresotate; sodium anisate; cinchonidine hydro-iodid; zinc and manganese chloride; ethyl and succinyl succinate; uranium and ammonium carbonate; acenaphtene; benzoates of lead, barium, mercury and silver; salicylates of cadmium, lead; lithium and sodium benzoate; barium benzene sulphate; potassium benzene disulphonate; potassium sulpho-benzoate; acid mono-iodo salicylate; bismuth and sodium benzoate; cinchonodin dihydro chromate; acid mono-chromo benzoic para; potash chromo salicylate.

None of the above are as sensitive as calcium tungstate, the selected crystals free from flaws being more sensitive than any of the double cyanides of platinum and other metals. Defective crystallization and impurities reduce the sensitiveness more than 50 per cent. Certain crystalline forme of calcium tungstate do not fluoresce at all.

The Röntgen ray powerfully changes the normal condition of vision. With strong tubes, one can easily see through the hand with the naked eye, when both are brought very close to the tube; moving objects are also seen plainly. For the first two or three seconds the eye perceives nothing, but by that time the ray has made some change in the eye and the sensitiveness is increased.

SOME NOTES ON ROENTGEN RAYS.

BY PROF. ELIHU THOMSON.

SOON after the publication of Prof. Röntgen's discovery it was pointed out by several observers that whenever Röntgen rays were given out in abundance the glass of the Crookes' tube was strongly fluorescent, and some went so far as to put forward the view that the rays had their origin in the fluorescence of the glass. When, however, it was found that bombarded platinum within the bulb was a more active source of rays than the bombarded walls of a tube,and permitted of focusing the rays, this view had to be abandoned. But even when the tube is arranged so as to bombard a platinum piece by cathode rays concentrated thereon by a concave cathode terminal the fluorescence of the glass is still produced, but far more evenly than in the other case, while the fluorescence in a good tube is confined to those parts of the glass walls only where exposed to radiation from the bombarded spot on the platinum.

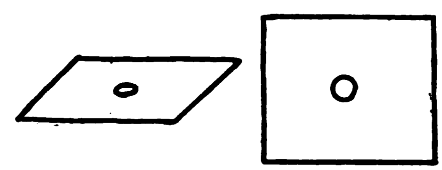
In other words, there is a dividing plane coincident with the plane of the platinum sheet and all the glass of the tube on the side toward the cathode is rendered fluorescent, while on the other side it is dark. Not only is this sharp division noticed, but the fluorescence is remarkably uniform and equally bright on the portion of the glass walls which are at equal distances from the spot on the platinum plate on the active side. This indicates that the intensity of the radiation, causing fluorescence from the platinum plate is sensibly the same, whether the rays emanate normally or at any angle, even to the direction of almost coincidence with the plane of the plate.

The use of a fluorescent screen or of photographic plates shows that the Röntgen ray emanation is sensibly as intense at all angles from the bombarded spot on a true plane of platinum, while, of course, the focusing effect is more sharp when the rays are used that leave the platinum at high angles, to the normal, or nearly in the plane of the sheet. This is, of course, due to the fact that, viewed edgewise (see the figure), the spot becomes almost a line of a length equal to the diameter of the spot.

This fact may be taken advantage of when extremely sharp focusing in any particular direction is required.

The above considerations lead at once to the conclusion that the fluorescence of the glass is in reality caused by and is an index of the intensity and distribution of the Röntgen ray emanation. There is still left the question as to whether, when the glass is bombarded by the cathode rays, such fluorescence as is produced is a direct result of cathode ray bombardment, or arises in turn from the Röntgen rays, which are a result of such bombardment. When a spot on the glass wall of a Crookes' tube is bombarded it will be found that sparks sometimes ⅛ inch long, can be obtained from the outer surface at the bombarded spot, and that if a terminal of a small Geissler tube be presented to the spot while the other terminals touch the hand, the Geissler tube is feebly lighted. Around the spot is a comparatively neutral zone, and beyond that a feeble effect can be obtained all over the glass wall at a proper distance from the terminals. Recent observations show a change in polarity, the spot bombarded being made negative at each discharge, while the other parts are positive, a neutral zone existing between them.

To test the question, or, rather, to illustrate the action of the Röntgen rays in causing fluorescence of the glass, some of the same glass was finely powdered, mixed with varnish and made into a screen instead of tungstate or platino-cyanide. It was found to give a feeble result, but sufficiently strong to allow the shadows of the bones in the fingers to be seen. From the fact that the fluorescence on the glass of a strongly active tube can be seen even in a room lighted by daylight, it would seem that the radiation which reaches the glass screen must have lost enormously in passing the glass wall of the tube. This follows from the feeble effect on the powdered glass screen, for we know that the glass wall is too thin to absorb the Röntgen radiation to an extent more than a moderate percentage of the total.



AN X-RAY EFFECT.

May it not be that the rays which are produced at the bombarded surface of the platinum are mixed with others of a lower wave length, which, while they can excite fluorescence of the glass to an equal or even greater degree than can the Röntgen rays, are absorbed or stopped by the glass wall, owing to its opacity for them? That such rays can exist and have this property has already been shown theoretically. Considering Röntgen rays as very high pitch transverse vibrations (a view which the writer tentatively adopted from the first), the bombardment possibly gives rise to other rays too low in rate of vibration to penetrate such materials as could be used to form a Crookes' tube. This view is favored by the fact that fluorescence of the glass can often be produced at lower exhaustions without giving Röntgen rays, and at highest exhaustions the glass is less fluorescent, though Röntgen rays are abundantly produced, which rays, however, possess the property of penetrating bone as well as flesh, and which will even traverse considerable thickness of brass and other metals. Prof. S. P. Thompson was one of the first to point out this difference in the character of rays produced at the very highest exhaustions from those at lower exhaustions.

Considerable testimony has been given of late tending to show that Röntgen rays have a peculiar effect on the tissues, removing hair, causing blistering of the skin, deep-seated pain in the joints, etc. To test this the writer exposed the little finger of his left hand for half an hour to the radiation of a strongly excited tube (single focus). The back of the finger was placed almost in contact with the glass and only about one inch and a quarter from the bombarded platinum within. It was thought that an effect equal to four or five hours' exposure at ordinary distances might in this way be produced in half an hour. For several days after the exposure no noticeable effect was produced, and the matter was given no further thought, but at present writing, eleven days after the exposure, the skin of the back of the finger is red, swollen and painful to the touch, and the finger feels somewhat stiff. It has begun to blister. The effect resembles a strong sunburn. The palmar surface is unaffected as yet. It was quite a week

[1] See The Electrical Engineer March 25 and April 1, 1895.

before any definite effect was noticed. The unquestionable result produced leaves room for the hope that Röntgen rays may be found to have a therapeutic value, though, of course, it is as yet doubtful if they can be superior to ordinary violet light except in power of penetrating opaque bodies.

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—VII.

BY LIEUT. B. A. FISKE, U. S. N.

RANGE INDICATING SYSTEM.

In the accompanying drawings, Fig. 23 is an electrical diagram illustrating the principle of the system, and showing one transmitting instrument T, and ten receiving instruments I, in circuit, each receiving instrument having an adjustable resistance in series with it, each adjustable resistance being in a metal box R. Fig. 24 shows in detail the mechanism by which in practice the contact C (Fig. 23) is moved along the resistance wire AB. Fig. 25 shows in detail the mechanism of the adjustable resistance inside of the box R, and Fig. 26 is a view of one of the receivers, or indicators, I (Fig. 23), with its resistance box R in position below it.

Referring first to Fig. 23, AB is part of a conducting circuit which includes the battery or other source of current, such as the electric light mains of a ship, connected through a suitable resistance, as shown in the cases of the helm indicator, steering telegraph and engine telegraph, in Figs. 1, 7, 10, and 11. T is a galvanometer which is connected in shunt with AB, one terminal being fixed at the point A, and the other terminal, or contact, C, being movable along the conductor AB. It will be clear that if the contact C is moved along the conductor AB, the difference of electric resistance, and, therefore, of electric potential or pressure between the points A and C will be varied, and consequently the extent of deflection of the needle or index of the galvanometer T may be controlled as desired, so as to cause said index to point to any scale-division or other mark or marks inscribed along its path. Connected in multiple arc with the galvanometer T are the two conductors + and —. Obviously these conductors will also be affected by the movement of the traveling contact C along the line AB, and will assume a difference in potential depending on the position of C on AB; so that if galvanometers I be connected to these conductors in the manner shown in Fig. 23, these galvanometers will respond to the movements of the contact C, for the same reason as does the galvanometer T. Furthermore, if all the galvanometers T and I be exactly similar, the needle deflections in all will be the same, and thus any indication caused in the galvanometer T will be repeated in the galvanometers I. Therefore, if T be the transmitting galvanometer, and if the instruments I be located at distant stations, it is plain that an operator at T, by adjusting the traveling contact S, can produce in his instrument a deflection which will instantly be repeated and shown at the distant stations in the receiving galvanometers I. It will be apparent, however, that if the galvanometers I are differently located with respect to each other and to the galvanometer T, so that in the circuit of one there is a different resistance from that which is in the circuit of the others, or if from any cause, such as rise in temperature, and consequent temporary loss of the magnet's strength, any galvanometer becomes less sensitive, means must be provided whereby said galvanometer may be adjusted or regulated so as to compensate for any such differences or changes, or, in other words, so that each receiving galvanometer may be so regulated that its deflections or indications will correspond to those of the transmitting galvanometer T. In the practical construction of the system these means are provided, and consist merely of an adjustable resistance placed in series with each galvanometer, and secured in a water-tight iron box R.

Turning now to Fig. 24, which shows in detail the means employed for moving the contact C along the wire AB, we see that the wire AB is wrapped in a spiral groove traced in an insulating cylinder D. The ends of the wire are secured to german silver springs, g, g, secured at the ends of the cylinder near the axis. The binding posts A and B are insulated from the metal box J, and their ends are prolonged about half an inch inside the box into cylindrical pins, or axles, a, a, which fit in the cylinder D, and press tight against the german silver springs, g, g, to which are secured the ends of the resistance wire AB. There is, therefore, a complete circuit from the binding post B to the german silver spring g, through the resistance wire that is wrapped around the cylinder, to the german silver spring g at the other end of the cylinder, and thence to the binding post A.

The cylinder is revolved on the axle AB by means of the handle H, which turns the screw S, and the gear wheel G, and thence the gear wheel G', which is secured to the cylinder D.

The contact C is secured to a stout piece of rubber that is secured on a nut N, that travels on the screw S. The pitch of the screw S and that of the spiral on the cylinder D are equal, so that, if the handle H be turned, the contact C will move with the nut N, though insulated from it, and press successively on different parts of the wire. The contact C is connected by the flexible wire W to the binding post C'. If the battery be connected to the binding posts AB, and if A and C be connected to the binding posts + and — of T in Fig. 23, it is clear that the act of revolving H will cause the same effect as

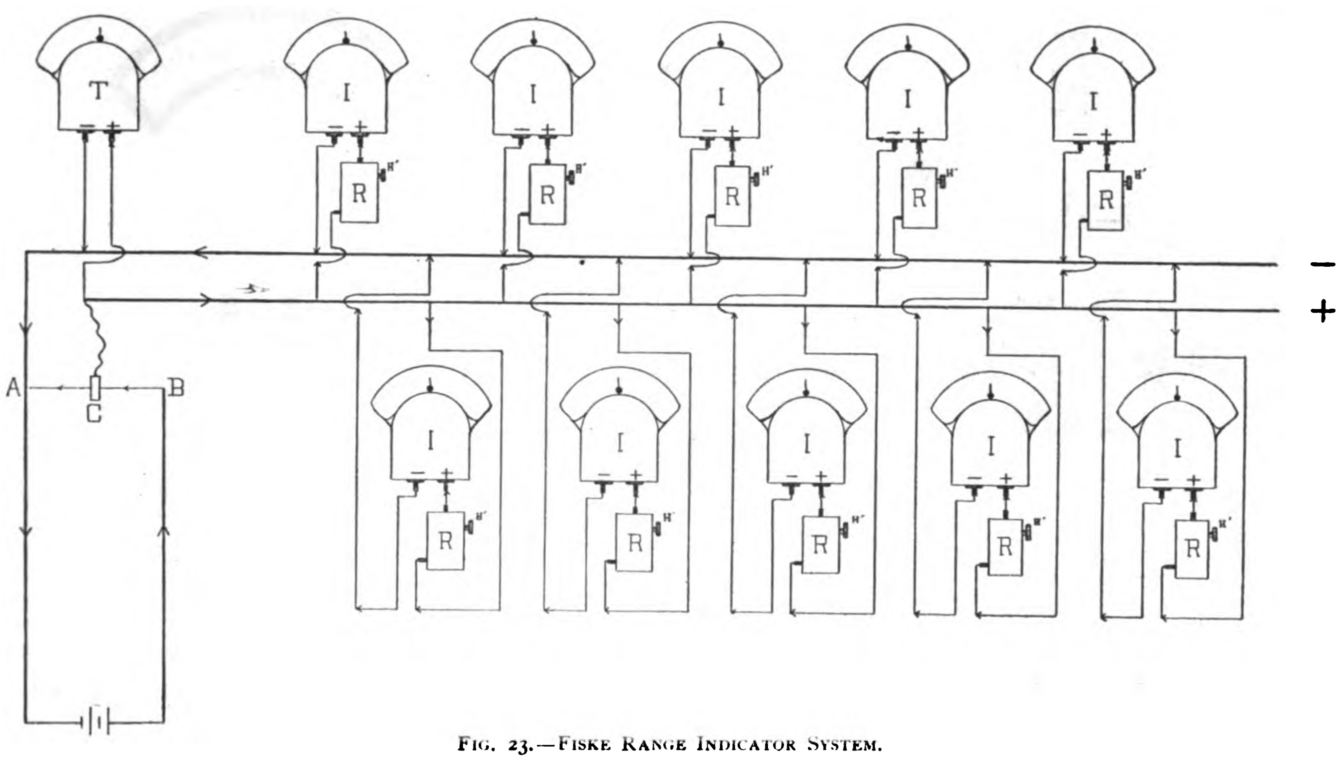


FIG. 23.—FISKE RANGE INDICATOR SYSTEM.

if the contact C were directly moved along the straight wire AB, in Fig. 23.

Turning now to Fig. 25 which represents the adjustable resistance in the box R, we see that the construction is nearly the same as that in the transmitting box just described. The resistance wire is, however, connected to the german silver spring at the center of its cylinder at the left end only, as the right end of the wire is secured to the insulating cylinder at the point P. The contact C'' is moved in the same way as is C in the transmitting box, Fig. 24, and is connected by the flexible cord W' to the binding post C'''. The current enters at the binding post A', passes thence to the german silver spring at the left end of the cylinder, to the resistance wire wrapped on the cylinder, to the contact C'', and thence to the binding post C'''. Clearly, if this apparatus be placed in series with any galvanometer I, and the handle H' be turned, the resistance in series with I will be varied and the deflection of I correspondingly changed.

The place for the transmitter T is near the reading instrument of the range-finder, so that any distance read from it can at once be made to appear on the transmitter and simultaneously on all the indicators in the ship.

To adjust the apparatus for use, connect the battery or other source of electricity and make the transmitter read, say, 29.50, or any other preconcerted number. Then make each receiver read the same number by turning the thumb wheel H'. The apparatus is now ready; but if there is time, it is best to try several preconcerted numbers in succession. It is better not to use the even hundreds in adjusting, because the graduations half-way between them are finer and give better opportunities for exactness.

The transmitting and indicating galvanometers are all similar, so that, in the event of accident to the transmitter, any receiver may be substituted for it. If this is done,, however, it will be necessary, of course, to verify the adjustment of the instruments, in the manner above described.

In case a battery is used, the one found most satisfactory for all this class of work is the "chloride" storage battery. It is extremely uniform in resistance and in electro-motive force, and requires almost no care, provided it be connected to the electric light circuit and charged once a week. To do this is very easy, as it only takes a little more trouble than is required to turn on an incandescent electric light.

The galvanometers can be secured directly to a bulkhead. If desired, they can be graduated to work in a horizontal position.

As far as giving accuracy of indications is concerned, the horizontal position is the best for a galvanometer, because the pivot of the needle is then vertical, so that the only friction possible is between the lower conical end of the pivot and the jewel in which it rests. From the circumstances of their use, the receivers must, as a rule, stand vertical; but there is no reason why the transmitters should not always be horizontal, both in service and when being graduated; and this is their proper position.

The later instruments are mounted in water-tight cases, and have the same construction as the instruments used in the helm indicator and steering-telegraph systems, illustrated in Figs. 6, 7 and 8.

Instead of being operated from a storage battery, as indicated in Fig. 23, the range-indicator circuit may be operated from the dynamo circuit, in the same manner as are the helm-indicator and steering-telegraph circuits; and the fact that the dynamo current is not uniform, but pulsating, is an advantage, because it gives the needles a minute vibration on their pivots, which is not sufficient to cause any difficulty in reading, but which prevents the needles from sticking.

The indicators should be so placed at the guns that they can easily be read by the gun captain, or other person charged with setting the sights, so that calling out by the voice will be avoided. A vertical position will, therefore, usually be best; and the indicators are graduated during manufacture while in that position. In case it is desired that one or more indicators shall lie horizontal, as may be the case in turrets, notice should be given in advance, in order that the indicators may be placed in that position during graduation. If the transmitter is placed below the protective deck, it should not, if it can be avoided, be put in a very hot place, because high heat diminishes temporarily the power of magnets, and this would render extra adjustment necessary on the transmitter.

The wires connecting the various instruments should have Navy standard insulation and be not less than No. 16 gauge. The mains should be laid, as far as possible, below the protective deck, with branches running up to each indicator, in order to minimize the chance of injury in battle.

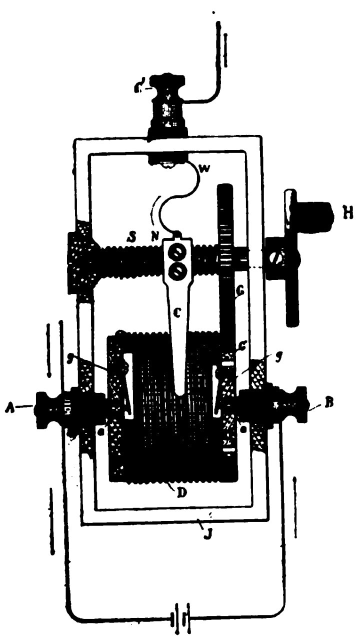

FIG. 24.

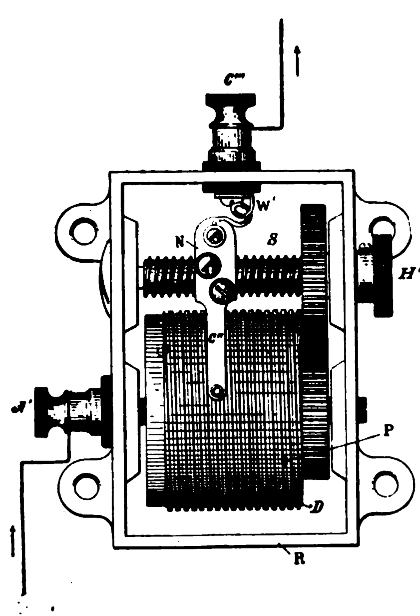

FIG. 25.

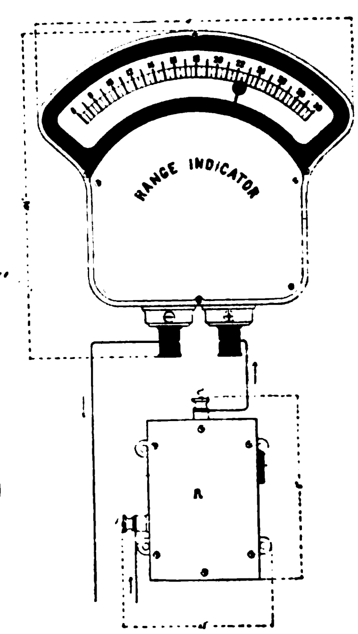

FIG. 26.

The rheostat which is placed in the dynamo circuit for cutting down the current of the range indicators, should be of the Carpenter form, in order to economize space, and should, when the e. m. f. of the dynamo is 80 volts, measure about 50 ohms; so that, with the 3.7 ohms resistance of the transmitter coils the current in the coil will be about one and one-half (1½) amperes. The rheostat should be capable, therefore, of carrying 1½ amperes without undue heating. It should be put in an accessible place in the dynamo room, where it can radiate heat readily, and for this reason should not be enclosed. Two separate wires are then to be run from the rheostat to the transmitter, so that the range indicator circuit will be independent of all parts of the lighting circuit, except in the dynamo itself.

PROTECTING THE HALIFAX FORTIFICATIONS.

The military authorities are laying cables for telephone connection between the various Halifax fortifications, which have heretofore been maintained by overhead wires. The headquarters station is in the citadel, and the cables radiate from that point. In connection with the military cable system each fort is to be equipped with a cable office, and men will be instructed and told off as operators.

WALKER & KEPLER, 531 Chestnut street, Philadelpha, have just finished the wiring in the new wing of the Aldine.

REPORTS OF COMPANIES.

THE ELECTRICAL MERCANTILE AGENCY.

CREDIT is the basis of all enterprises in modern commerce, and as a necessary consequence, it is a matter of vital importance that the financial soundness and responsibility of every concern buying material or issuing obligations should be thoroughly determined and clearly known. Such work as establishing the proper rating of the personnel of any trade or industry is at once delicate and difficult, but when well done, it amounts literally to the insurance or underwriting of one's business, if care is taken to observe the cautionary hints that come from the rating bureau. The electrical trade has long been in need of a sizing up of this character, and never more so than at the present moment, when the passing away of bad times is likely to invite that undue expansion of indebtedness which is in itself a menace to continued prosperity. Efforts have been made before the present time to render the resources of financial information in the electrical field specifically available, but it is not until now that the results can be spoken of as satisfactory. The general commercial agencies have therefore been depended on hitherto, but as other trades have grown and have at last demanded their own, separate data, handled by experts in each branch, so the electrical industry has reached the same point.

We are glad to call the attention of our readers to the work of the Electrical Mercantile Agency, of 318 Broadway, which has lately been founded by Mr. P. M. Mowrey, and is now in full swing. It aims at several important objects, which the general manager's training should well qualify him to achieve. Mr. Mowrey at one time had charge of the credits of the New York Edison Company, when it was a supply licensee for General Electric apparatus, and was subsequently treasurer of the New York Electric Equipment Company, thus acquiring an intimate experience for ten years with credit work. His staff is also well selected, and is in direct touch with over 6,000 correspondents throughout the country.

To begin with, by work extending over the past two years, the Electrical Mercantile Agency has sifted and classified the credits of between 12,000 and 15,000 concerns of all kinds that are in one way or another within the electrical field. These ratings are given in the Agency's "Credit Reference Book," a handsome, well-printed volume, to which is furnished a double key; one, alphabetical, quoting the estimated worth, and the other, numerical, giving the credit status. This book of over 300 pages, is renewed twice a year, and a correction circular is issued every week, giving brief news of judgments, mortgages, transfers, etc. The volumes come out in April and October, so as to secure promptly the changes which are likely to occur at the beginning or middle of the year, and which could not get into a book out on January 1 or July 1. The service of the Agency is rendered at the annual fee of $125, which includes all the literature above-mentioned, and 100 special confidential reports on any concern in any line, although, of course, the special business to which attention is devoted is electrical. Extra reports are furnished at $1 each. The Agency introduces a novelty also in this class of work, by furnishing special reports, of its own volition, if any conditions seem to demand it. Through its wide and responsible ramifications, the Agency also undertakes a collection business.

It will be seen that the new departure of the Electrical Mercantile Agency is one whose importance to the electrical trade cannot be exaggerated. It has been a reproach to this trade that the average of credit is extremely low, the rapid advance of the art having drawn in far too many adventurers and over-sanguine dealers. But even if the number in this class were larger, there is now no reason why its unreliability should play any part. All that is necessary is to know its ratings and get the Agency report on its credits. The sound and honest merchant has only a hearty welcome for such safeguards.

THE NILES, MICH. MUNICIPAL PLANT IN TROUBLE.

A special dispatch from Niles of November 9 says: "It is possible that some of the city's creditors may seize the electric works and city lighting plant. The outstanding debt is nearly $240,000, and the council finds itself unable to pay bonds long since due and held by N. W. Harris & Co., of Chicago. The treasury is empty and the taxes are not due until December. Last June the taxpayers voted down a special assessment and the prospects are that they would do so again."

FINANCIAL.

AN INCREASE OF SOUTHERN NEW ENGLAND TELEPHONE STOCK.

A call is to be issued immediately to stockholders of the Southern New England Telephone Company, meeting Nov. 17, to vote upon the question of authorizing the company to increase its capital stock from $2,000,000 to $3,000,000. The plan of the company, however, is to issue to stockholders at $90 the new shares of $100 each in the ratio of one to three of the 16,750 shares representing $1,675,000 of capital stock now outstanding, thus increasng the capital stock to $2,233,-300. The company will use the proceeds of the new stock in retiring next February its convertible five per cent. debentures amounting to between $300,000 and $400,000 and in extending and improving its plant. The returns for ten months of the present fiscal year indicate that the company is earning about 10 per cent. a year upon its outstanding stock. The ten dollars conceded to subscribers to the new stock is treated by the company as a distribution of surplus, and at the existing market price would make "rights" worth a little more than $3 each.

LEGAL NOTES.

A TROLLEY PARALLEL PERMANENTLY ENJOINED IN CONNECTICUT.

The text of the important decision given on Nov. 10 by Judge G. W. Wheeler, in the Superior Court, New Haven, Conn., granting a permanent injunction against the Hartford and New Britain trolley parallel of the New Haven Steam Railroad Company lines, shows that the decision does not turn directly on the question of public necessity and convenience, but on three points: First, that the trolley line layout occupies an appreciable part of the public highway, thus bringing the case within the general street railroad law; second, that its route exceeds the powers conferred by the charters of the three construction companies; and, third, that under the law the steam company is a valid party to the suit. The finding of facts, however, upon which the injunction is granted indicates clearly that Judge Wheeler is of opinion that public convenience and necessity do not justify the parallel. That finding emphasizes the former decision of Judge F. B. Hall against the necessity and convenience of a parallel, refers to the fact that the layout is on a line where there are few houses, and that the real motive to its construction is the obtaining of a direct competing line between the two cities. The decision is extremely prejudicial to the interests of the many projected trolley parallels in the State, indicating that the courts will insist on very strict construction of charters and upon strong proof of public necessity and convenience before competing trolley parallels will be authorized. This result of the long and bitter two years' contest also forecasts another session of the Legislature to be marked by sharp controversies of the electric and steam railroad interests. The Hartford-New Britain case will probably be among them.

RIGHTS OF TELEPHONE SUBSCRIBERS.—DECISION AT INDIANAPOLIS.

At Indianapolis, Ind., on Nov. 6, the State Supreme Court decided a case involving the right of a subscriber to have his telephone connected with that of another subscriber with whom he wishes to talk. August H. Fehring, a druggist at Columbus, Ind., and one of the subscribers of the Central Union Telephone Company, permitted a Dr. Hudson to use his telephone to call his horse from a neighboring livery stable after the doctor had had his own telephone taken out of his office because of some difficulty with the telephone company. The company objected to this, and finally refused to connect the drug store and livery stable until Mr. Fehring should assure them that he did not intend to let Dr. Hudson use his telephone. Mr. Fehring brought suit against the telephone company, under the statute which provides that every telephone company "shall within the local limits of such telephone company's business, supply all applicants for telephone connections and facilities with such connections and facilities without discrimination or partiality," and that its refusal to do so shall be punished by a forfeiture of $100.

The telephone company defended on the ground that they

had a contract with Mr. Fehring, binding him not to let others use his telephone, and also took the ground that the statute simply required the company to furnish an instrument to any one who requested it, but left it at liberty to establish regulations as to making connections between different instruments. But the court holds that under the provisions of the statute, telephone companies are not only required to furnish an applicant the instrument and properly connect it at the exchange, but it is also their duty to supply all the connections and facilities necessary to the use of the instrument. The opinion, by Judge Monks, says:

"Merely furnishing an applicant with an instrument and connecting the same with the exchange is not a compliance with the statute. This alone would not enable such person to use the telephone instrument. After the telephone instrument was furnished appellee and connected with it was the duty of appellant each time when requested by appellee to make such connection as would enable him to converse with the person named without discrimination or partiality, and for a failure to do so the appellant is liable to the appellee for the statutory penalty."

DECISION AGAINST CONTINUANCE OF WATSON TELEPHONE SWITCH PATENT.

A stipulation has been made by Judge Showalter in the U. S. Circuit Court, Chicago, in the case of the Western Electric Company against the Western Telephone Construction Company, which has been construed to mean that the monopoly as to the switch hook patent is terminated. The order concerned the Watson switch patent, which the Western Electric Company had contended did not expire until 1900. However, it was discovered that a prior patent had been taken out in Canada, and in consequence, by a previous ruling of the court, the patent expired July 30, 1895. This established the fact that the invention is now public property.

The Western Electric Company is not disposed, however, to believe that its business is hereby jeopardized. Speaking on the subject, George P. Barton, attorney for the company, said:

"The stipulation that was made in the United States Circuit Court was not of such far-reaching importance as has been claimed. It simply amounts to this, that the patent, which is known as the Watson switch patent, No. 270,522, expired on July 30,1895. The Western Telephone Construction Company or any other company or person is therefore free to employ the Watson invention, and, while we expect to gain damages for the infringement of the patent prior to its expiration, we cannot, of course, now obtain an injunction.

"But the Watson switch patent, although it was one of the more important patents on telephone apparatus, was not one of the controlling patents. It does not relate to the switchboard, but is the hook on which the receiver in the subscribers' telephone outfit is placed.

"It is evident that the expiration of a patent on an invention that is so small a part of the complicated telephone apparatus cannot bring about a revolution in the business by throwing it open to everyone who wishes to undertake telephone making."

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 110th meeting of the Institute will be held at 12 West Thirty-first street, New York City, on Wednesday, November 18, 1896, at 8 o'clock, p. m. A paper will be presented by Mr. H. Ward Leonard entitled "Volts vs. Ohms; Speed Regulation of Electric Motors." Complete working apparatus kindly furnished by the Crocker-Wheeler Electric Company, will be used to illustrate the practical operation of the system.

NEW YORK ELECTRICAL SOCIETY.

The 177th meeting of the New York Electrical Society will be held at Columbia College, Madison avenue and Forty-ninth street, on Thursday, Nov. 19, at 8 p. m. Mr. Joseph Sachs will deliver a lecture on "Horseless Carriages." The lecture will cover the general principles involved, and review the progress made in European developments as well as in those of this country. The leading details and features of the various forms of horseless carriages will be pointed out, and special attention will be drawn to the most recent and improved examples in the art, including machines propelled by steam, gas, oil and electricity. The lecture will be illustrated by stereopticon. Ladies are invited.

THE HENRY ELECTRICAL SOCIETY.

The Henry Electrical Society announces the following lectures for the next meeting: On November 20 Mr. Joseph Sachs will deliver a lecture on the present status of horseless carriages. The subject will be treated in a popular manner profusely illustrated by lantern slides.

On December 4 Prof. F. B. Crocker will explain the "Principles of Electro Chemistry." By the aid of experiments and the lantern the treatment will be rendered especially interesting and particularly valuable.

On December 18 Dr. L. H. Laudy will describe the different methods of "Lantern Projection," including searchlights.

ST. LOUIS ENGINEERS' CLUB DISCUSSES STREET LIGHTING.

At the last meeting of the Engineers' Club of St. Louis, Mr. M. L. Holman presented informally the proposed specifications and form of contract prepared by the Board of Public Improvements for the lighting of the streets, alleys and public places of the city of St. Louis for a term of twenty years beginning in 1900. The most important features of the proposed contract were the exclusive use of 32 candle-power incandescent lights in place of the arcs of 2,000 nominal candle-power, all wires to be underground. St. Louis was the first large city to adopt electric lighting on a large scale and has therefore had a very wide and valuable experience, arcs being used for the streets generally and incandescents for the alleys, parks, and also for a number of suburban streets. Valuable practical experience had therefore been had in the use of both kinds of lights, and the adoption of the incandescent light to the exclusion of the arc is the result of a careful investigation into the illumination given by the two systems. The duration of the contract was made twenty years in order that the city might secure reasonable bids.

Discussion followed by Messrs. R. E. McMath and B. H. Colby, who with Mr. Holman formed the sub-committee of the board which had this work in hand. They emphasized the fact that their conclusion was based upon actual observations made on the two systems of lighting in regular service in this city. The arc lights give a very unequal distribution, the illuminations being very intense at one point and there being but little light midway between. The incandescent lights, on the other hand, are placed much nearer together and afford a much more uniform light.

Further informal and general discussion followed in which Messrs. Robt. Moore, Eayrs, Crosby, Barth, Van Ornum, Ockerson, Pitzman, Wise and Philip Moore participated.

CHICAGO ELECTRICAL ASSOCIATION.

The association is doing good work this year. It announces as its paper for November 20. "Daily Problems in Long Distance Telephony," by E. L. Andrews.

AMERICAN STREET RAILWAY ASSOCIATION.

Secretary Penington is already inviting suggestions as to topics to be presented in papers and discussions at the next meeting of the association, to be held at Niagara Falls, N. Y., in October, 1897.

PERSONAL.

A PRESENT TO MR. F. M. PEDERSEN.

Dr. S. S. Wheeler, president of the Crocker-Wheeler Electric Company, presented Mr. F. M. Pedersen, the assistant engineer of the company, on Nov. 9, with a very handsome silver card receiver with the following inscription: "To Frederick Malling Pedersen. For distinguished services as Adjutant at Headquarters and in the Field, October 29th, 30th and 31st. 1896. From Schuyler S. Wheeler." In explanation it may be said that Mr. Pedersen had charge of arganizing and drilling the employés of the Crocker-Wheeler Electric Company, for the purpose of taking part in the great "Sound Money" Parade on the 31st of October, and it was in token of Dr. Wheeler's appreciation of the heartiness with which this work was entered into by Mr. Pedersen and the thoroughness with which it was carried out, that the above presentation was made. Dr. Wheeler is as enthusiastic on the sound money question as he is quick to recognize extra efforts of this character on the part of his associates. The marching of the Crocker-Wheeler regiment was magnificent, and aroused favorable comment all along the line.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Central Stations:

THE CENTRAL STATION AT NICE.—A detailed description of plant, with plans and elevations of the various sections of the building and a diagram of the distribution system. A 600-ampere-hour storage battery forms part of the outfit. "L'Ind. Elec.," Oct. 10, '96.

GAS ENGINES IN CENTRAL ELECTRIC STATIONS.—By R. Knocke. It is shown beyond a doubt that the block system of lighting in Germany is feasible, and the various calculations based on the value of gas to be 85 cents per 1,000 cubic feet. From Dingler's Polyt. Journ. in "Progr. Age," Oct. 15, '96.

Dynamos and Motors:

DESIGNING A BIPOLAR DRUM DYNAMO.—By Rankin Kennedy. Eight short rules giving the simplest arithmetical processes for designing an armature. Lond. "Elec. Rev.," Oct. 16, '96.

SUGGESTIONS FOR PROSPECTIVE PURCHASERS OF ELECTRICAL MACHINERY.—By Wm. Baxter, Jr. Author makes some valuable suggestions as to the relative sizes of engines and dynamos. "Western Elec.," Oct. 17, '96.

THE ALTERNATING MOTOR FOR FARM WORK.—By Robert E. Dallas. Author mentions a motor designed by J. J. Wood which has given good service on a farm, practically the only trouble mentioned being the heavy starting current. The time-saving element is quite an important factor. "Elec. Eng'r., Oct. 28, '96.

Electro-Physics:

FLUORESCENCE OF SODIUM AND POTASSIUM VAPORS.—E. Weidmann and G. C. Schmidt have been investigating the fluorescence of sodium and potassium vapor, and find that it is very marked, the sodium being green and the potassium red. The spectra which these vapors yield under the influence of electrical discharges appear to correspond to the fluorescence spectra, and it is pointed out that Stokes' rule holds for these as for other cases of fluorescence. It is suggested, in the conclusion of the paper, that the establishment of fluorescence for the vapors of the metals would throw light on some hitherto unexplained astrophysical phenomena. The original paper may be found in the "Annalen der Physik und Chemie," 1896 2), 57, 447. Note taken from Lond. "Elec. Rev.," Oct. 2, '96.

Isolated Plants:

ELECTRICITY AT ST. ELIZABETH'S U. S. HOSPITAL FOR THE INSANE.—A full description of a plant laid out without regard to expense, but with the intention of producing the most perfect installation obtainable. Six thousand lights have been installed and motor power will be employed for many purposes. "Elec. Eng'r.," Nov. 4, '96.

TEST OF AN ISOLATED ELECTRIC LIGHTING PLANT RUN BY A GAS ENGINE.—By S. A. Beyland. From a consideration of the figures and diagrams it may be seen that where only a small number of lights is required gas used directly is much cheaper. Above 30 lamps it is decidedly cheaper to use the gas for fuel in driving the dynamos. "Progr. Age," Oct. 15, '96.

Lighting:

ELECTRIC CAR LIGHTING.—A system patented by Morris Moskowitz, in which a dynamo is run from the car axle and which has an automatic speed regulator; current does not commence to be generated until a speed of eight miles is reached; storage batteries are used to supply current when the cars are not in motion. Plans and elevation accompany the descriptive matter in "Railroad Gaz.," Oct. 31, '96.

ELECTRIC LIGHTING AT THE NATIONAL EXPOSITION AT GENEVA.—By R. B. Ritter. The first of a series of articles. Both arc and incandescent lamps are used, but the ordinary practice was not followed in every case; 240-volt lamps were tried, although not with very great success. The Alioth transformer, which transforms from a rotary into a direct current, also receives some mention. "L'Ind. Elec.," Oct. 10, '96.

Miscellaneous:

A GAS ENGINE DRIVEN ELECTRIC INSTALLATION.—The Empire Theatre (England) used to be supplied by the electric light company and found that by having their own gas engine plant, using corporation gas, a saving of $650 was effected in nine weeks. Lond. "Elec. Rev.," Oct. 2, '96.

REOSTENE, A NEW RESISTANCE METAL.—Dr. Harker, of Owen's College, Manchester, before the Brit. Assoc., described some experiments made by Mr. A. Davidson and himself on a new alloy for commercial electrical resistances, which has been called "reostene." This alloy is the outcome of a number of experiments made with a view to find a material of a higher specific resistance than iron, capable of carrying heavy currents, and having only a moderate temperature coefficient. Lond. "Elec. Rev.," Oct. 2, '96.

THE HOOKHAM ALTERNATING CURRENT METER.—A picture of the instrument, with a detailed description of the improvements which have been made on it during the past year. Lond. "Elec. Rev.," Oct. 9, '96.

Railways:

THE CITY OF ST. LOUIS AND ITS TRANSPORTATION SYSTEM.—Besides a general review of the railway development and general traffic, Mr. Richard McCulloch gives an account of the railway cars in St. Louis, and Mr. Winthrop Bartlett gives details with plans of the power stations in that city. Finally the roadbed is separately treated. "Str. R'y. Journ.," Oct., '96.

TRACK AND TRACK JOINTS.—By M. K. Bowen. Paper read before the St. Louis Street R'y Convention. Author discusses construction, maintenance and bonding. Prices of track construction and costs of maintenance are of especial interest. "Street R'y. Journ.," Nov., '96. "Elec. Eng'r.," Oct. 28, '96.

MODERN OVERHEAD CONSTRUCTION.—By Benj. Willard. Paper read before the St. Louis R'y Convention. Author enumerates various types of pole construction and gives prices, as well as their depreciations. "Str. R'y Journ.," Nov., '96. "Elec. Eng'r," Nov. 11, et seq.

DAILY INSPECTION AND CARE OF CAR EQUIPMENT.—By James B. Cahoon. Author explains in a short article how inspecting of cars is carried on in practice. "Elec. Age.," Oct. 24, '96.

A NEW ELECTRO PNEUMATIC BRAKE.—By Fr. Miron. Some modifications of the Westinghouse brake. "La Rev. Techn.," Oct. 10, 96.

STREET RAILWAY TRUCKS.—By J. N. Akarman. Paper read before the St. Louis R'y. Convention. Speaker dealt with the principles involved in the street railway truck, with the requirements for the service, and with the value of the single and double truck. "Elec. Eng'r.," Nov. 4, '96.

Roentgen Rays:

SOME RECENT ROENTGEN RAY WORK.—By Elihu Thomson. Author dwells on the value of the stereoscopic method of observation.—"Elec. World," Oct. 10, '96.

SEARCH FOR SOLAR X-RAYS ON PIKE'S PEAK.—By F. Cajori. Assuming the possibility of solar radiation to contain X-rays, the terrestrial atmosphere might possibly absorb them, hence experiments at very great heights were performed, but no evidence whatever of the presence of Röntgen rays was obtainable. "Am. Journ. of Science," Oct., '96.

Telephony, Telegraphy, etc:

ELECTRICAL DISTURBANCE IN SUBMARINE CABLES.—By W. H. Preece, F. R. S. Paper read before section A, of the British Assoc., Sept. 23, '96. Author points out the various disturbances, explaining a disturbance to be the result of the expenditure of energy in the wrong place. He explains the effects of electrostatic and electromagnetic induction, and then devotes his attention to telephone cables exclusively. Lond. "Elec. Rev.," Oct. 2, '96.

THE NEW WESTERN UNION TELEGRAPH OFFICE IN BUFFALO.—By A. C. Terry. One of the new types of office in which the motor dynamo takes the place of batteries. Detailed description, with illustrations, in "Elec. Eng'r.," Oct. 28, '96.

THE MODERN POWER HOUSE.—By Richard McCulloch. Paper read before the St. Louis Convention. Author gives some points on the selection of location, on the building, on the steam operating apparatus and steam consuming machinery. "Str. R'y. Journ.," Nov., '96. "Elec. Eng'r.," Nov. 4 and 11, '96.

THE ECONOMY OF THE ELECTRIC MOTOR.—The great advantage of the motor for crane work is pointed out and editorially it is remarked that the mechanical more than the electrical engineer urges their use. Lond. "Elec. Rev.," Oct. 16, '96.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

IMPROVED REGULATING MECHANISM FOR ARC LAMPS.

UP to within the past two years the operation of a clutch arc lamp on a constant potential circuit was considered impracticable. The invention of the enclosed arc method of illumination called for a lamp which would draw and maintain a long arc efficiently, and opened up a new field for the clutch lamp. The old-style lamps were replete with mechanism, consisting of a train work of wheels, rack rod and escapement movement; also adjustable parts subject to the influence of weighted levers, tension springs, etc. These complicated parts naturally required frequent adjustment and repairs.

In the "Pioneer" long burning arc lamp there is a bold departure from old methods. A glance at the accompanying cut will show that the rack work and clumsy mechanism have been superseded by a simple and effective clutch. The arc is sprung by a pair of solenoids which lift the armature

PIONEER ARC LAMP CLUTCH MECHANISM.

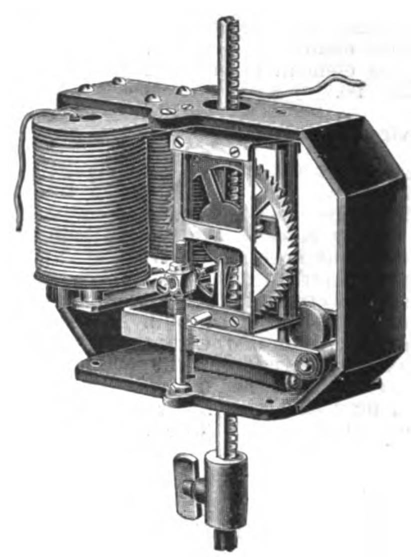
and lazy clutch and with them the carbon rod. The amount of iron in the moving parts is so proportioned that the current passed by the lamp is practically constant for any position of the armature. The lamp will pick and maintain an arc of about ⅝ of an inch in length. As the carbons waste away, the armature gradually descends until the clutch mechanism rests on the stops, as shown in the engraving. This releases the rod and allows the upper carbon to feed. The clutch is then instantly raised slightly from the stops. The feeding of the lamp is almost imperceptible and unattended by any flickering in the light.

It will be noted that there are no springs, wheels or other adjustable parts in the mechanism; hence there is nothing to get out of adjustment. When the carbon rod has reached the lower limit of its travel, the lamp is automatically cut out of circuit.

AJAX ARC LAMP MECHANISM.

THE lamp mechanism illustrated in the accompanying engraving is that of the new Ajax enclosed arc lamp for which many distinctive features of merit are claimed and which especially adapt it for lamps of the long burning type. Such lamps must not only be simple as regards the number of parts used in their makeup, but the few parts used must be of such a nature as to require the least possible care in operation; else one prominent feature of this type of lamp is forfeited and frequent inspection will largely take the place of short interval trimming, causing annoyance and a charge on the debit side of the ledger.

A rack feed was selected for the Ajax lamp because of the advantages possessed by this construction for lamps which are inspected and cleaned only at long and irregular intervals, which custom usually prevails where long burning lamps are used. The rack feed, of itself, is a simple and positive mechanism, but the usual train of gears has been avoided. There is no gearing used in the Ajax lamp except the one pinion which engages loosely the rack rod and supports the latter at a position determined by the strength of the series solenoid. By reference to the engraving it will be seen that there can be no slippage of the carbon rod and consequently no feeding of the upper carbon until the vertical vibrating pin is allowed to fall below the horizontal adjustable pin by the consumption of the carbons and the consequent lowering of the cores of the solenoid. This positive feed feature well qualifies it for locations where there is considerable vibration, such as in mills,



THE AJAX ARC LAMP MECHANISM.

where looms or heavy machinery cause a continual jarring, or steamboats, and in other unstable situations.

The absence of frictional clutches and other tight fitting parts eliminates the possibility of the carbons sticking, the "feed" being accomplished by inappreciable increments through the medium of gravity and a weighted escapement pawl which vibrates very slowly. The free working of the feeding mechanism is a very important item, for, as stated above, a lamp which is trimmed only at intervals of weeks should be designed to feed evenly throughout its entire run of 150 hours, whether the carbon rod be polished frequently or only kept approximately clean.

It is claimed that the simple and easy working mechanism of the Ajax lamp will appeal to that large class of producers of artificial light who look for efficient service from lamps which require only ordinary care.

The escapement pawl is case hardened, all steel parts are nickel plated and the entire absence of springs and dash pots are among the features which commend the Ajax lamp for durability and reliability.

Pomeroy, Woltmann & Co., of 43 Cortlandt street, New York, are manufacturers of this already popular lamp.

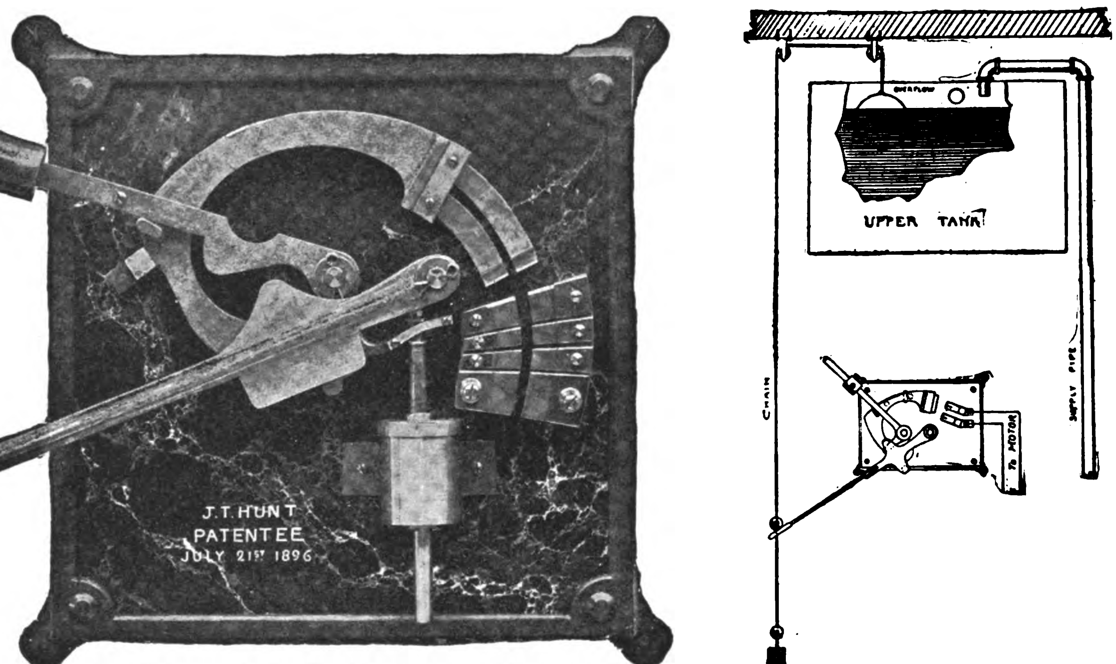
MR. LEWIS G. ROWAND, of the Universal Fire Alarm Company, 925 Chestnut street, Philadelphia, has received and printed a very complimentary letter from President Brown, of the Old Dominion Steamship Company, with regard to the quality of their work and apparatus. The Duplex boxes are well built, ingenious in principle and up to date in every detail.

ZIMDARS & HUNT AUTOMATIC SWITCH FOR STARTING MOTORS.

THERE are many situations in which power is required at irregular intervals and where the expense of an attendant to switch a motor in and out would be prohibitive. As an example we need only cite the many instances where water has to be pumped into a tank situated on the roof or some other elevated position. In such cases evidently an automatic switch is required. The most recent apparatus of this type are the automatic switches invented by Mr. J. T. Hunt, and manufactured by Messrs. Zimdars & Hunt, 127 Fifth avenue, New York.

Our engraving, Fig. 1, shows the switch designed for automatically starting and stopping motors up to and including 5 horse-power. Fig. 2 shows the same in position after cutting off current and stopping the motor, the water in the tank having reached the desired level. As the water level is lowered, the float in sinking raises the weight on the chain running through the slot in the bottom lever of the switch, until the lower adjusting ball reaches the lever.

In lifting, it gradually raises the top lever until it reaches a vertical position. The weight on this lever then carries it over by gravity, causing it to strike the cam and make contact and start the motor and pump. Any desired depth of water can be maintained in the tank by altering the distance between the adjusting balls on the chain running through the slot of the switch lever.



FIGS. 1 AND 2.—ZIMDARS & HUNT AUTOMATIC MOTOR SWITCH.

The switch illustrated in Fig. 1 is arranged so as to allow the current to enter gradually through a resistance, thus preventing undue sparking at the commutator. The switch thus takes the place of the starting box or rheostat usually operated by hand. As will be seen, an air cushion or dash pot is provided so that the switch can be readily adjusted to throw in the current over a period extending from five to thirty seconds.

These switches have been in practical operation for over five months. Among the locations in New York in which they are at work are the following: Equitable Gas Works, Fortieth street and East River; electric light plant at 45-49 Bleecker street; the Cook Apartment House, 117th street and St. Nicholas avenue; residence of Jas. C. Pyle, Fifty-third street and Fifth avenue; Hotel Logerot, Eighteenth street and Fifth avenue; Chas. Yandell, decorator, Eighteenth street and Fifth avenue; the Carrollton, Seventy-sixth street and Madison avenue, controlling a 5 horse-power Eddy motor.

The Broklyn Edison Company also has one of these switches at work in its Pearl street station, and Mr. Peabody, of the same company, has one in his residence. W. E. Quimby also uses these switches almost exclusively in connection with his electric pump work.

MR. EUGENE H. ABADIE, of the Wagner Electric Mfg. Company, St. Louis, was a visitor to Chicago a few days ago when his many friends were pleased to see him. The Wagner Company is marketing some admirable apparatus.

CREDIT FOR THE FIGHT AGAINST THE WATSON PATENT.

Great interest is being manifested everywhere in the recent surprise sprung upon the electrical public in the discovery of an old Canadian patent whose existence has invalidated the famous Watson switch patent, No. 270,522, regarded as one of the bulwarks of Bell telephone control of the situation. It is natural that there should be a desire to enjoy the credit for such a victory. We gather from the Standard Telephone and Electric Company, of Madison, Wis., that they are entitled to the glory and honor, and in support of their claims they send us the following copy of a very striking letter from Barton & Brown, well known as the legal representatives of Bell telephone and Western Electric interests in such matters. The letter runs as follows:

"Chicago, Ill., Nov. 3, 1896.

"Messrs. Morris & Morris, Attorneys Standard Telephone and Electric Company, Madison, Wis.

"Gents: Referring to the suit of the Western Electric Company vs. The Standard Telephone and Electric Company, of Madison, Wis., on patent No. 270,522, and the plea setting up Canadian patent for the same invention of July 30, 1880, we have to say that your plea was the first notice of any kind leading us to even suspect that there was a foreign patent which limited the terms of the United States patent. It was only yesterday that we saw a copy of the Canadian patent. It is, of course, a bar to the suit, and we shall accordingly direct that the suit be dismissed at complainant's cost.

(Signed.) "BARTON & BROWN."

The Standard Company are inclined to regard this as about as specific a proof of their right to the credit of the fight and victory as anything that could be produced.

GALE'S COMMUTATOR COMPOUND.

We illustrate in the accompanying engraving a most useful adjunct to every dynamo and motor tender. Any one who has had charge of a dynamo or motor knows well the tendency which they have to spark and cut at the commutator. The Gale's commutator compound, as shown in the cut, is convenient for use, will not gum the brushes, and, judging from the magnificent testimonials received by the K. McLennan Company, of the Marquette Building, Chicago, who are the sole manufacturers, it will absolutely prevent all sparking and prevent cutting. It is an easy thing to try, and as the McLennan Company will send a sample to all who request it, no superintendent should at least be ignorant of what it is.

MR. P. B. DELANY has located his city headquarters at Room 1011, Syndicate Building, Liberty and Nassau streets.

THE STANDARD TELEPHONE CO'S APPARATUS.

Special announcement will be found in our advertising pages from the Standard Telephone & Electric Company, of Madison, Wis., with regard to their apparatus for telephone exchanges and private installations. Among the exchanges enumerated are San Jose, Cal., 600; Portland, Ore., 1,500; Marquette, Mich., 600; Jacksonville, Fla., 700; Madison, Wis., 600. The Standard Company are the representatives in America of the excellent Milde microphone transmitters, which have been illustrated in The Electrical Engineer, and which are well known for their endurance and sensitiveness, having been awarded a great many prizes and medals. The company will be glad to send estimates for the complete equipment of exchanges, toll lines, etc.

A PROTEST FROM THE WALKER CO. AGAINST TRUST METHODS.

Since the publication in our columns last week of the news in reference to the proposition of the General Electric "Trust," seeking to exclude competitors, we have received a copy of a circular just issued by the Walker Manufacturing Company, of Cleveland, making a warm protest against such methods, and warning street railway companies against committing themselves in the way sought. The Walker Company renews its offer to protect any users of its apparatus, and says to its customers: "We address this circular to you so that you may be on your guard and avoid tying yourself to a combination which proposes to secure from you abnormal prices for electrical machinery in the near future." The Walker Company closes by asserting that this attempt is due to the large capital of the trust upon which dividends cannot be earned by fair competitive methods.

ADVERTISERS' HINTS.

MR. WILLIAM TAYLOR, 203 Broadway, New York, calls attention to a sale of 80 enclosed arc lamps, the sale being the result of installing 20 lamps on trial three months ago.

THE BERLIN IRON BRIDGE COMPANY illustrate a parabolic truss bridge designed and built by them at Waterbury, Conn. They contract for all sorts of structural iron work, corrugated iron roofing and fireproof shutters and doors.

THE AMERICAN BATTERY COMPANY, 40 W. Quincy street, Chicago, guarantee the uses of their storage cells against all infringement.

MR. MAX OSTERBERG, E. E., 27 Thames street, New York, is now the representative of the Correspondence School of Technology, Cleveland, Ohio, for Greater New York.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, remind the trade of the last eight years' record of the Packard lamp and claim they are to-day the most efficient and satisfactory lamps on the market.

"THE OTTO CYCLE GAS ENGINE" is the name of a new book by Wm. Norris, dealing with all the details of the subject. It may be obtained by addressing The Electrical Engineer.

McINTOSH, SEYMOUR & CO., Auburn, N. Y., call attention to their gridiron valve horizontal engines for direct connected service. They make this engine of any power, single cylinder, tandem or cross compound, vertical or horizontal and also various other kinds of engines.

NEW YORK NOTES.

MR. FRANK X. CICOTT. The Ansonia Brass & Copper Compnay, 19 and 21 Cliff street, New York, announces that it has secured the services of Mr. Cicott, who will represent its electrical and metal departments.

THE BUFFALO ELECTRICAL LABORATORY is starting as a branch of the Bliss School of Electricity, with rooms on the eighth floor of the Erie County Bank Building. Mr. Frank C. Perkins is the local manager.

THE CLONBROCK STEAM BOILER COMPANY are one of the companies who have not felt greatly the depression of the ante-election period. At the present time they have their staff at work busily engaged on orders ahead with encouraging prospects for good future business.

MR. J. I. AYER, of the American Electric Heating Corporation, Boston, was a visitor to New York last week, and spoke most hopefully of the outlook in the heating field. The company is pushing into a great many new territories and has to deal every day with new problems attendant upon the revolution it is effecting.

MR. H. P. COPELAND, for some time past with the house of The E. S. Greeley & Company, in charge of the catalogue department and the filling of orders, is now associated with James S. Barron & Company, of 147 West Broadway, in charge of their electrical supply department. Any supplies ordered from the Greeley catalogue will be promptly attended to.

STANLEY & PATTERSON, 32-34 Frankfort street, New York, issue copy of a letter from the Prudential Insurance Company, of America, signed by Mr. G. A. Warren, chief engineer, showing some remarkable results secured with 12 Fleming woven wire dynamo brushes which have been in use since February, 1894, on dynamos used 16½ hours daily. The brushes have worn down 1¼ inch, and the commutators show practically no wear.

MR EDWARD P. SHARP, of Buffalo, N. Y., who deals in new and second hand electrical apparatus and railway supplies, has issued his latest list of material on hand under date of November 12. The list includes almost everything necessary for the equipment of either a lighting or railway plant, and in addition to the price of each item is included a memorandum as to the condition in which the things are, which is of considerable importance to the purchaser.

NEW YORK STENCIL WORKS, 98-102 Nassau, New York, report business improving. They are having a brisk demand for name plates, of which they are extensive manufacturers. They sell largely to the electrical trade, and have such concerns on their books as the Edison Phonograph Works, Orange, N. J.; Western Electric Company, Interior Conduit and Insulation Company, and many others. This firm has been established since 1868. The New York Stencil Works manufacture other specialtes also, such as patent rubber telegraph wheels, steel letters and figures, steel dies, inks and materials, figure wheels, railroad seals, check protectors, brass labels. They do also die sinking and general engraving.

NEW ENGLAND NOTES.

MR. F. S. MINOTT, the general manager of the National India Rubber Company, was a New York visitor last week, stopping off in the city on his return to Bristol from the Sesqui-Centennial at Princeton.

MR. GERALD HART, president of the Hart & Hegeman Manufacturing Company, Hartford, Conn., paid a visit of a few days' duration to Chicago and made his headquarters at the Western office of the company, which is in charge of Mr. George S. Searing.

THE GENERAL ELECTRICAL ENGINEERING COMPANY, Tremont Building, Boston, Mass., is the name of a company recently organized as consulting and designing engineers. The officers of the company are E. W. Bailey, president; E. A. Bailey, treasurer, T. W. Byrne, manager.

CROWN WOVEN WIRE BRUSH COMPANY, of Salem, Mass., report an increasing demand for their brushes from all parts of the country. The Osburn Electric Supply Company, of Chicago, has taken the agency for Illinois; and the Michigan Electric Company, of Detroit, for Michigan. Both of these companies carry a large stock of the popular Crown brushes and can fill orders immediately.

MESSRS. WILLIAMS, COUCH & WHITMAN, Boston, Mass., have been appointed sole selling agents in the United States for the Ericsson Swedish microphone, and in this connection it is interesting to note that they have been compelled for want of room, to change their address to 196 Summer street, in which building both their office and factory are now located. The telephone business done by this firm in the past has been responsible for this change, and with these increased facilities the company are prepared to take good care of the imported microphone which they will handle.

WESTERN NOTES.

THE WESTERN ELECTRIC COMPANY, Chicago, report a very large demand for the Sunbeam lamps, especially for the 2, 4 and 6 c. p. lamps. Large orders have been filled for use in sign and decorative work.

O. K.—The manufacturers of the celebrated "O. K." weatherproof wire are placing on the market an elegant white underwriter's wire and also a very fine fire and weatherproof wire having an inner fireproof braid covered with an outer black weatherproof braid. The Electric Appliance Company are prepared to furnish these wires and are always glad to furnish samples and submit prices.

THE ARMORITE INTERIOR CONDUIT COMPANY, of Detroit, report that they are very well pleased with the amount of business they have done during the past few months, and also with the prospects for the future. Messrs. Austin and Cummings of this company are on the alert all the time, and are frequent visitors to Chicago, where they have done considerable work and are always heartily welcomed by their many friends.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. NOVEMBER 25, 1896. No. 447.

Electric Lighting.

THE NEW STATION OF THE SOUTHERN ELECTRIC LIGHT AND POWER CO., PHILADELPHIA, PA.

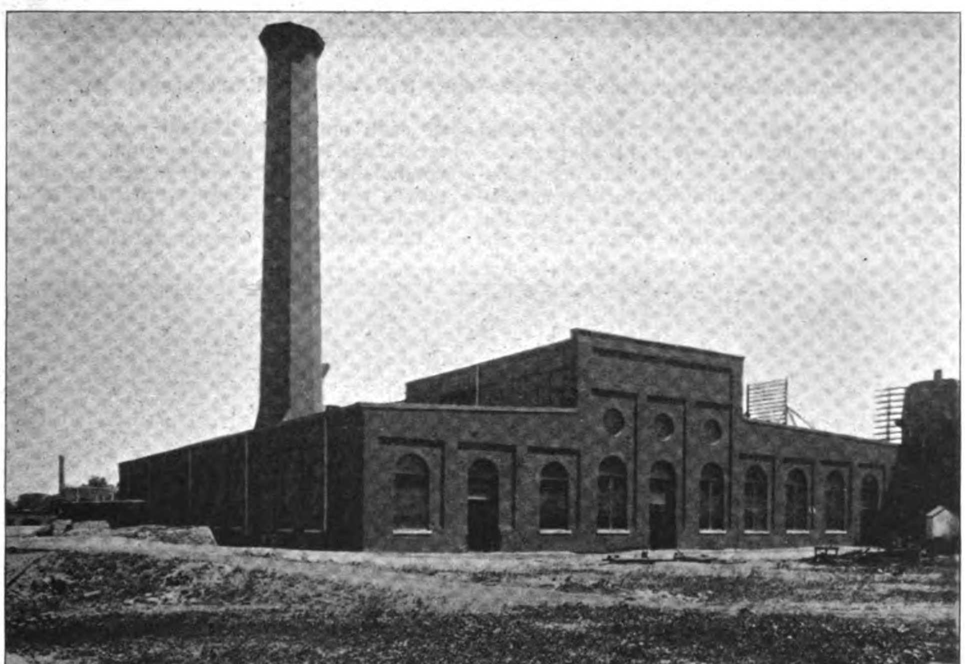
THE electric arc lighting service of Philadelphia is perhaps the most complete and extensive of any American city. Not only upon every main thoroughfare in the more closely built portions of the city and throughout the crowded sections, but upon avenues and the finely macadamized roads reaching far into the suburban sections, the most excellent service is maintained all night, and every night in the year.

The many lighting systems, together with the vast power plants required for the service, are owned and operated by private corporations, and the light is furnished to the city under contract. The stock of the companies is largely held by residents of the city and is widely distributed among all classes. The companies are a success from an investor's standpoint, largely due to the excellent business management for which they are noted.

One of the most prominent and progressive of these corporations is the Southern Electric Light and Power Company. The lighting service is furnished by this company for the most densely populated portion of the city lying south of South street, between the Delaware and Schuylkill Rivers. Until recently the company has owned and operated a number of plants, some of which they still hold for future use, should they be needed.

During the spring of 1895 they began the erection of the plant which is illustrated in the accompanying engravings. The site selected is a commanding position overlooking the Schuylkill River, with unlimited space for building and every natural advantage. With knowledge acquired by many years of experience in the service, the managers of the company started out with the determination to build the best lighting plant that could be designed. Competitive preliminary plans were submitted by leading engineers; those presented by Charles Edgerton, M. E., of Philadelphia, were selected, and the work proceeded at once under his personal supervision, while the architectural features were directed by John T. Windrim. Every part of the work, as it progressed, passed under the experienced eye and was pushed forward to completion by the indomitable energy of the managers of the company.

The plant, as built, is arranged for almost indefinite extension without alteration of the work already done. The buildings, including the immense smokestack, were erected by Messrs. Doyle & Doak, well known contractors, of Philadelphia. The main building is 204 feet in length by 174 feet in width, and the structure is steel throughout. The entire outer walls of the buildings and chimney are of selected stretcher brick laid in dark mortar. The general effect, while neat and pleasing, is massive and substantial, the structure plainly showing the purpose for which it was designed.



South Front of Main Building, Southern Electric Light & Power Co., Philadelphia, Pa.

One of the most difficult problems encountered by the engineers was that of water supply. It was found that, for condensing purposes, from six thousand to twelve thousand gallons per minute would be required, allowing for reasonable increase. To provide this, it was found needful to drive a tunnel some 1,300 feet through varying conditions of rock, quickstand, water gravel and river mud, to the bottom of the Schuylkill River. The work was promptly commenced and as promptly stopped by the contractor when the magnitude of the undertaking confronted him. A hurried consultation between the engineers and managers resulted in the work being undertaken at once by them. The necessary equipment was procured, competent men employed, and the tunnel completed.

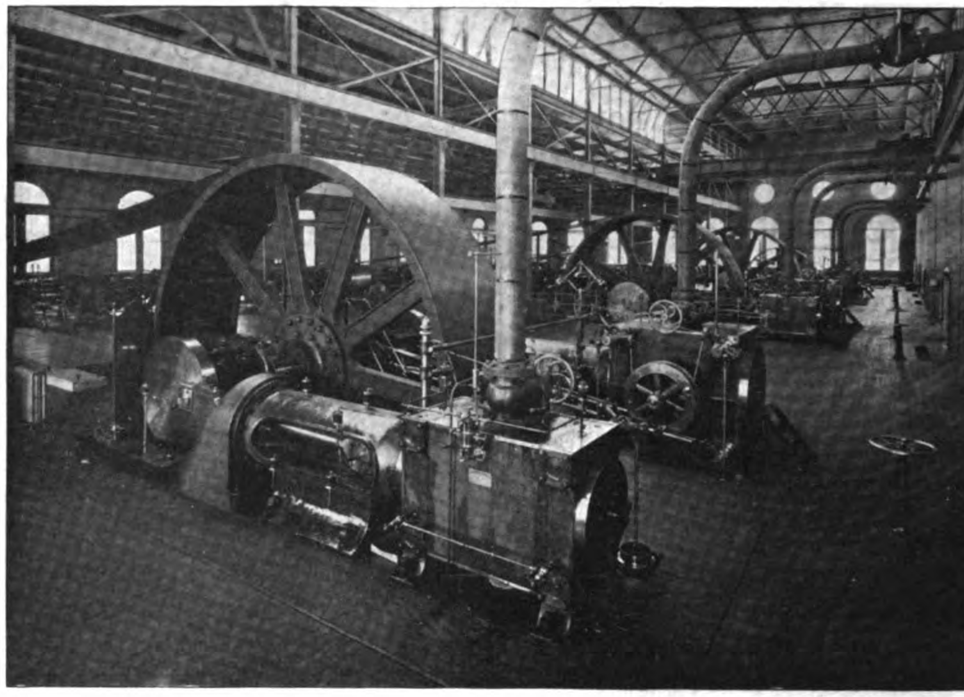
As the result, a circular conduit, 48 inches in diameter, inclosed by massive walls of brick, stone and cement, extends from the plant to the river, with ample provision for properly filtering the water before it enters the tunnel. Through this tunnel the water flows to the plant by gravity, and is taken by the condensers from a point immediately beneath them.

Probably the most striking features of the mechanical equipment of the plant are its remarkable simplicity, completeness and thorough interchangeability. Steam is supplied for the plant by twenty boilers of 150 horse-power each. They are of the horizontal return tubular type and have many novel features in construction and setting. They were built by the Coatesville Boiler Works and are made of Lukens' special firebox steel.

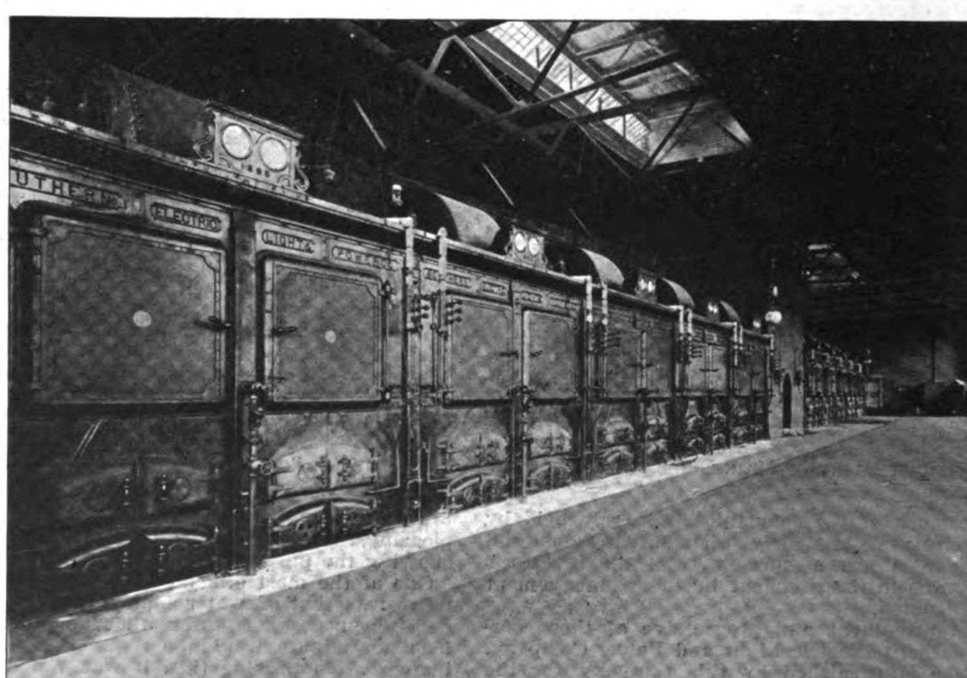
Four pairs of cross-compound engines of Corliss type, with a total capacity of 3,500 horse-power, drive the dynamos. The engines are of massive design and equipped with every modern device required for safety and close regulation. The weight of each engine is 230,000 pounds—the driving wheels alone weighing 70,000 pounds each. The engines when running condensing require but fifteen pounds of steam per horse-power per hour. They were built by the Hooven, Owens & Rentschler Company, of Hamilton, O.

The condensers were designed by Edwin Reynolds and built by the Edw. P. Allis Company, of Milwaukee, Wis. They are their regular type of jet condensers with special features required for the heavy service to which they are subjected.

The entire main systems of piping were constructed by



ENGINE ROOM, SOUTHERN ELECTRIC LIGHT & POWER CO., PHILADELPHIA, PA.

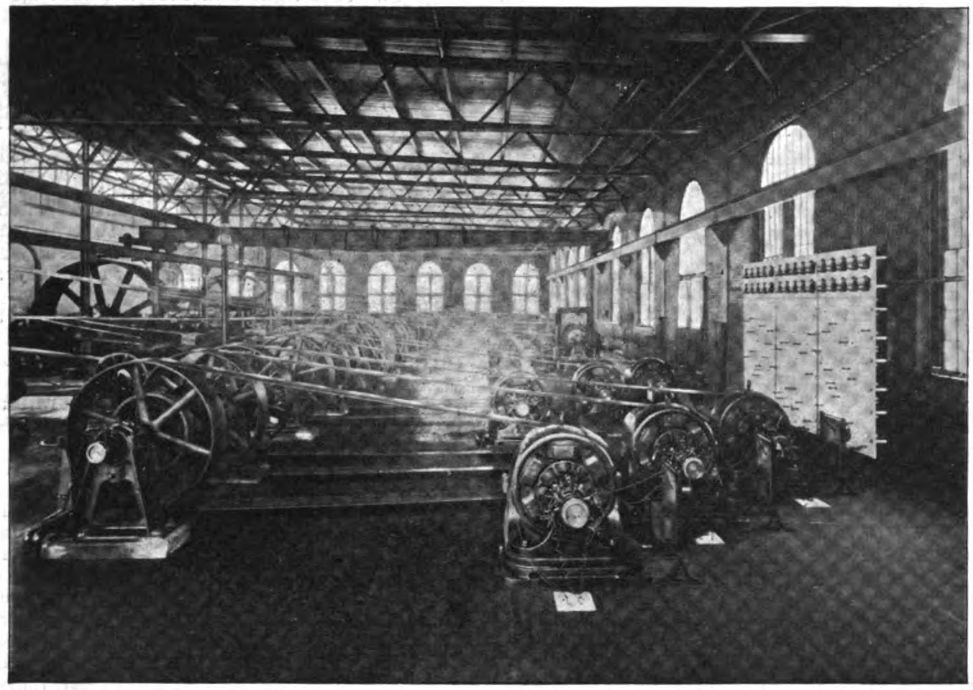


BOILER ROOM, SOUTHERN ELECTRIC LIGHT & POWER CO., PHILADELPHIA, PA.

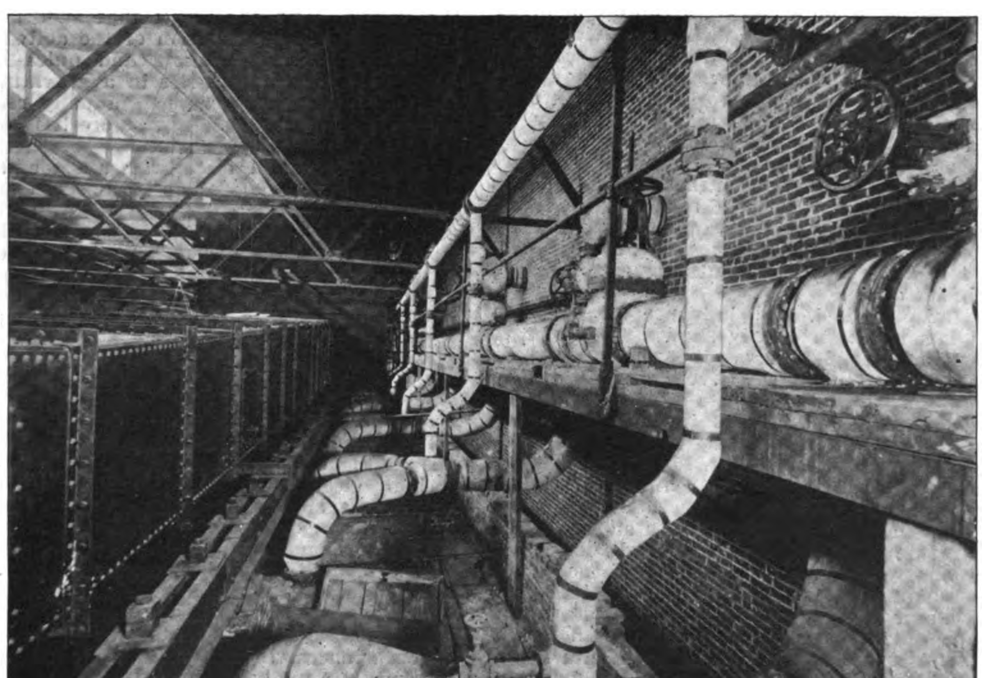
Messrs. Best, Fox & Co., of Pittsburg, Pa. The fittings of the high pressure system are steel forgings. The exhaust system is equipped with L. Schutte & Co.'s safety device for condensing systems. The pumps for water supply were furnished by the Snow Steam Pump Company, of Buffalo, N. Y. Two styles of feed water heaters are used, one in the vacuum system and one auxiliary. They were built by the Keystone Engine and Machine Company, of Philadelphia.

The system of power transmission embraces some novel features worthy of note. The driving belts are all of leather and were made by Charles A. Schieren & Co., of New York. The main belts are 64 inches wide by 164 feet long; the counter drives are of the same width, 93 feet long, all three-ply. To make the belts the hides of 2,305 heavy cattle were used, also 1,720 pounds of cement and three months' labor for twelve men. The belts weigh 13,700 pounds.

The shafting weighs 125,000 pounds. Each dynamo has an independent clutch and can be thrown on or off without interfering with any other machine. Any dynamo in the plant can be driven by any engine in the plant without the shafting carrying the weight of engine belts and pulleys not in use. This feature is accomplished by the use of hollow shafts or sleeves with main clutches for all engines. All clutches are of the Hill pattern. By an ingenious arrangement of the drives for counter shafting, loose lower belts on the dynamos are entirely avoided. There is not an idler nor a tightener in the plant. The shafting and attachments were built by the George V. Cresson Company, of Philadelphia.



DYNAMO ROOM, SOUTHERN ELECTRIC LIGHT & POWER CO., PHILADELPHIA, PA.



HIGH PRESSSURE MANIFOLD CONNECTIONS, SOUTHERN ELECTRIC LIGHT & POWER CO., PHILADELPHIA, PA.

The dynamos are of the Wood and Westinghouse types. The switchboard was built by the General Electric Company. In addition to the arc lighting service, the company is thoroughly well equipped for and is furnishing current for incandescent lighting and power purposes.

The officers of the company are the following: John M. Mack, president; James M. Mack, vice-president; W. J. Manning, treasurer and general manager, and Charles Edgerton, consulting engineer.

INSULATION.

BY PROF. W. M. STINE.

A RECENT editorial in The Electrical Engineer calls attention to the break-down in insulation, which is such a frequent source of loss and annoyance. It very clearly lays open what is perhaps the weakest point in electrical construction. Even a casual review of the subject suffices to show that great progress has been made since the early days, not only in the insulation of electrical machinery and apparatus, but of conductors and fittings; but great as this progress has been, the real advances have but fairly begun. Until recently, insulation has not received anything like scientific investigation, and, with the exception of a few manufacturers, only the crudest attempts have been made to improve the insulation by proper selection and careful working of material.

Recent papers by Mr. C. E. Skinner, and Messrs. Sever, Monell and Perry, give results of great value, and outline methods for testing, which, if carefully extended, would soon place us in possession of much useful data. Mr. C. P. Steinmetz has also made some excellent contributions to the subject.

Insulating materials exhibit three important properties, which influence their behavior under the applied stress of an electromotive force: (a) Insulation resistance; (b) disruptive strength; (c) hygroscopic qualities.

(a) All insulating substances, of whatever nature, may in general be regarded as conductors of extremely high resistance. For our present discussion we need not consider these substances as conductors by electrolytic separation, but rather as acting like extremely viscous liquids when subjected to stress; and thus temperature increase, by rendering them more viscid, will lower their insulating qualities.

(b) The power of insulating material to withstand disruptive discharges is really of more consequence than their insulating qualities. These substances may be considered to possess an elastic limit, with reference to the stress of an electromotive force, which, when exceeded, a rupture or break occurs. Important as are such tests, which show the influence of temperature on insulating power, they should be supplemented by tests which shall show their resistance to break-down throughout the range of working temperatures. This tendency to disruptive discharge may not inaptly be compared to the brittleness of hard substances.

(c) The hygroscopic quality of insulating materials refers to their tendency to absorb moisture from the atmosphere. As a consequence, their effective insulation is lowered, the increased conductivity being due to the moisture, rather than any change in the material itself. The leakage through this film of moisture is apt to char the insulating material and lead to complete break down.

In all tests, so far published, the influence of this hygroscopic element has not been clearly shown. In order to obtain satisfactory and complete data, the tests should be so conducted as to bring out quantitative values for these several properties. The temperature-rate of change of insulation resistance should be conducted in an enclosed atmosphere, as far as possible freed from moisture, heat being preferably applied by electrical means. The material having been previously thoroughly dried, will then show truer values for temperature changes.

The disruptive tests may be made by use of a step-up transformer or rotary transformer, and should be conducted under the above conditions with reference to dry atmosphere. Finally, tests made at any given temperature, but with variations in the percentage of moisture in the atmosphere, will show the influence of moisture on insulation and breakdown resistance. It is needless to add that such data would be of the greatest value in all classes of electrical construction, replacing mere guesswork by something approaching to certainty.

The insulation demanded by electrical conditions presents a most trying mechanical problem. Since all metals are conductors, insulation can only be effected by use of comparatively weak construction materials. Somewhere in the apparatus all the strain of its movable metallic members must be borne by a layer of comparatively weak material. For example, in the armatures of motors and dynamos, the strain of the torque on the conducting wires must be carried by the insulation. But examples are as numerous as the applications of electricity. In switches, the insulation between the blades and the handle is a source of weakness that as yet has not been satisfactorily overcome, and the difficulties of keeping large switches tight and firm are matters of common experience. The effects of constant pressure and high temperatures will inevitably loosen the best joints.

These mechanical difficulties also manifest themselves in an especially aggravating way in the overhead construction of trolley lines. Strain insulators, hangers, frogs and crossings, are far from being strong and reliable. If further argument be needed, let the reader attempt to design a section insulator or a crossing. But when to these mechanical difficulties are added the necessity for high insulation in all kinds of weather, with the assurance that all such devices will soon become coated with a layer of soot and dirt, the problem is so exacting that it cannot be successfully solved with the materials now obtainable. Here is certainly a wide field for development.

With the extension of electric traction to the operation of elevated and steam railroads have come new and exacting requirements for durable insulation under all conditions of weather. A most interesting chapter could be written on the problem of insulation for the third rail and feeders carried on the superstructure.

Though a great deal may be written on the subject of insulation, as much may be said on the care to be exercised in the application and use of insulation. In dissecting transformers, dynamos and motors, one can not but observe many evidences of careless work in construction. In many places the insulating covering of the wire is abraded, and poor winding often brings layers near each other with a dangerously high potential difference. Some extra strain thrown on such apparatus must sooner or later cause a burnout. In the shunt coils of a widely used make of arc lamp, the core being in circuit, a very thin insulation is used between the core and the winding. The self induction of these coils being very high, the strain of throwing the lamps on and off, and of static discharges during a thunderstorm, results in numerous cores being burned out.

But leaving the manufacture of apparatus, we find great carelessness in regard to saving the insulation from undue strain. Switches are opened on circuits carrying heavy currents with little thoughts of the consequences. In fact, the only consideration seems to be to make such a quick break as to avoid arcing. But what becomes of the energy which would otherwise start the arc? It spends itself throughout the system, with the result that sudden and severe strains are placed on the insulation of the active circuit. From this standpoint, circuit breakers and quick-break, or spring-impelled switches, only assist in aggravating this strain. The ideal condition would be to gradually reduce the current in a circuit to a small amount before it is opened.

Let us consider the conditions present in a loaded circuit. Each portion of the circuit has absorbed a certain amount of energy to establish about it an electromagnetic field, and when the circuit is a solenoid with an iron core, the energy stored in its magnetic field is considerable. Let the current be opened suddenly and the energy of its electromagnetic field is at once returned to the line, each portion of the circuit generates an electromotive force proportional to the strength of its field, and its time rate of change; or, to employ the familiar expression,

$$e = -\frac{dN}{dt}.$$

In sections where the flux is high, as in the armature, and the series and shunt coils of the field, it is readily seen that a high electromotive force of self induction results when the circuit is abruptly opened, and this electromotive force may be enormously higher than that to which such parts are subjected in normal operation, causing a proportionate strain on the insulation. It is noteworthy that such strains usually come on apparatus when it has become greatly heated from long running, and in consequence of the high temperature, the insulation is at its weakest. We also find the same chain of occurrences, though lessened in amount, when the main current is rapidly increased or diminshed by switching a feeder. Bad as these conditions are in constant current circuits, they are greatly emphasized in the case of alternating currents, by resonance and capacity effects.

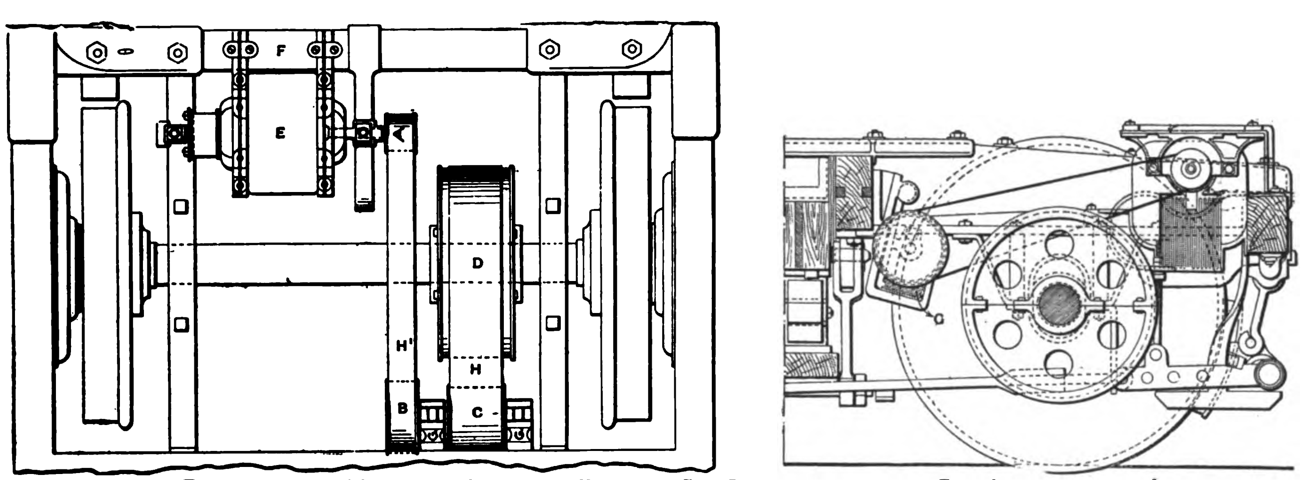
It seems that such conditions ought not to be so generally overlooked. Switches, and especially circuit breakers, should be provided with some device for more gradually opening or closing the circuit. Shunt windings of dynamos and motors might be protected by non-arcing discharge points, properly placed.

THE MOSKOWITZ ELECTRIC CAR LIGHTING SYSTEM.

DURING the past year experiments have been made on the cars of the Pennsylvania Railroad with a system of car lighting by means of storage batteries charged from a dynamo driven from the car axle. The system employed is that of Mr. Morris Moskowitz, of the National Electric Car Lighting Company, of New York, and the result of the trials has led to the equipment of a chair car on the Santa Fé Railroad, running between Chicago and Kansas City.

The system comprises a dynamo and its driving gear, a storage battery divided into two sets, a switchboard and a lamp circuit in the car. As will be seen in Fig. 1, the dynamo E is fastened to the rear of the car truck F, where it can be conveniently inspected. The transmission of power from the car axle to the dynamo is effected through a spring-cushioned counter shaft G, which is fastened to the truck bolster. On the car axle there is clamped a split wood pulley D. From this pulley the belt H drives the pulley C on the counter-shaft G. The other pulley B on the counter-shaft drives the belt H, which is directly connected with pulley A on the dynamo E. Both these belts are of double thickness. Another view of the spring-cushioned counter-shaft G is given in Fig. 2. The shaft is provided with a pair of helical springs in such a manner that the shaft and pulleys are able to give and take, and in this way cushion the vibrations of the car axle. The dynamo is entirely encased in a steel cylinder, which protects it from dust and water. The brushes are of carbon, and are so adjusted that they collect in both directions of the armature's rotation.

The dynamo is self-regulating under variable speeds. When the train has attained a speed of eight miles an hour the dynamo begins to generate its normal pressure of 45 volts. Should the train run at 60 miles an hour, the dynamo would be very little higher in electro-motive force, such is the regulation for a wide range of armature speed. This is accomplished by winding the fields differentially, so that an increased speed of the armature weakens the fields. In this manner the e. m. f. of the machine is maintained practically constant over a wide range of speeds of the car.



FIGS. 1 AND 2.—MOSKOWITZ SYSTEM OF ELECTRIC CAR LIGHTING FROM THE CAR AXLE.

The switchboard, which is generally placed in one of the closets of the car, has a number of ingenious features. As the system is entirely automatic, the controlling devices are all combined on the switchboard, Fig. 3. A is the main switch, which controls every circuit pertaining to the dynamo. If, for any reason, the dynamo is desired not to generate, all that is necessary to do is to open this switch. A 1 is the switch of the main light circuit. B is an ammeter showing the quantity of current generated at any time, and B 1 is a small resistance coil for the light circuit, which can be used if desired, but is not necessary. C is a special 12-point switch, which will be referred to later. E, F, G, H, and I are electro-magnetic devices, which control the dynamo and automatically change the polarity in accordance with the direction in which the train travels. Provision is also made for automatically opening and closing the main circuit between the dynamo and the storage battery, by taking advantage of the difference of pressure existing at times in either of them.

The 12-point switch C is used to control the whole system as follows: Two sets of storage batteries are used. One set is always connected to the dynamo-charging circuit, while the other is feeding the lamp circuit. When the battery on the lamp circuit is exhausted, the 12-point switch is turned, thereby switching the charged set on the lamp circuit and the exhausted set on the dynamo circuit to become charged again. It is impossible to change one and forget the other, as these operations all take place with one turn of the switch.

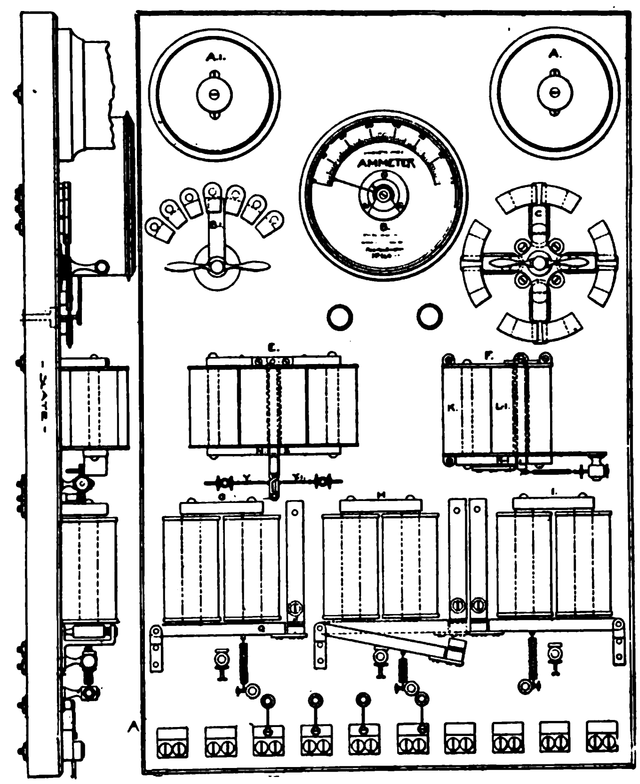


FIG. 3.—SWITCHBOARD, MOSKOWITZ CAR LIGHTING SYSTEM.

The storage batteries used in this system are made on a new design, by the company, for the sole purpose of electric train lighting. The standard equipment for a 60-foot passenger coach consists of 12 sixteen candle-power incandescent lamps in the car and one in each vestibule, making 14 lamps all told. We are indebted to the "Railroad Gazette" for the accompanying illustrations.

THE CANAL PROTECTIVE ASSOCIATION has sought to get State Attorney General Hancock to prevent alleged violations of the law in regard to the use of the towpath of the Erie Canal for Niagara power subway purposes. If the canal towpath exists for useful purposes it is hard to see what better use it could be put to than to furnish a way for the power wires.

LIGHTING A CATHEDRAL.

The introduction of a complete system of electric lighting into the Cathedral, East Logan Square, Philadelphia, was celebrated by a special public illumination and by a concert with a choir of sixty voices. The lighting effects obtained are admirable.

STATEN ISLAND ELECTRIC POWER COMPANY.

The Electric Power Company's property at St. George, S. I., has been resold by the referee. The purchaser was Paul D. Cravath in behalf of the Richmond Borough Electric Company, recently organized in the interests of Erastus Wiman. The business has accumulated under the receiver, Albert Boardman, nearly $80,000 in cash which, with the assets now realized on, will nearly liquidate the indebtedness of the company, and relieve Mr. Wiman of liability as endorser.

THE LIGHTING PLANT FOR YALE.

Inquiry fails to confirm the statement of the "Yale News" that the university authorities are planning an electric plant to supply all the university buildings. The matter has been examined and it has been found that the expense would probably be much higher than that of gas. The electric lights, however, have been placed in the new Phelps building, and their use may be somewhat extended. Under the present plan each student is responsible for the gas used in his room, and the statistics show that the cost is not excessive. On grounds of convenience many of the undergraduates favor the change.

LARGE ILLUMINATED SIGNS IN BOSTON.

The new Grand Theatre in Boston has gone in heavily for electrical signs. The Boston Edison Company has recently built and started for them, on the street mains, a big sign which goes right across the front of the theatre. It uses 625 lamps of 16 c. p. The upper line has the name of the house and the lower gives the prices of admission. The contract is that the sign shall be lit up three full hours every day. The theatre also has a sign built by the Edison Company a year or more ago, containing 300 lamps. It is placed diagonally across the corner sidewalk. Both these huge signs, taking nearly 1,000 lamps, are kept burning at once, and a great show is made, which attracts attention, excites comment in conversation and in the newspapers, and this pays the enterprising proprietor, W. Lothrop.

FLY WHEEL RUPTURE IN THE NO. 2. ROCHESTER, N. Y. STATION.

A defective fly wheel in the No. 2 plant of the Rochester (N. Y.) Gas and Electric Company burst a few days ago, breaking two steam pipe lines, endangering the lives of six men, and doing damage to the tune of $1,600. The engine room in which the accident occurred is 110 feet below the level of the street and 30 feet below the bed of the river. The wheel weighed twenty tons, with a 42-inch face, and a diameter of 18 feet. The accident happened about 2 a. m., throwing the city streets into darkness by the stoppage of a dozen generators. One of the engineers was badly scalded and burned. The exact cause of the trouble has not been determined.

MORRISTOWN, N. J., has taken up the subject of underground wires, with a subway commission, of which Mayor Quayle is a member. The citizens are also petitioning for the replacement of gas lights by electricity.

LITERATURE.

ELECTRIC WIRING SPECIFICATIONS FOR INCANDESCENT LIGHTING—By Geo. H. Kimber. New York, 1896, C. H. Irwin & Company; 59 pp.; 4½x6½. Flexible cover. Price, $1.25.

This little work is intended as an aid to architects and electrical engineers, and contractors in general, to guide them in the method of drawing specifications covering complete wiring installations. The author has very carefully sifted his material and introduced only the best and most up to date methods. As a matter of course we find here the general methods for direct and alternating two and three wire systems, as well as molding and conduit work of the various types now in general use. The author very properly added extracts from the Rules of the National Board of Fire Underwriters, which are always a handy thing to have about when drawing specifications. The little work ought to be of considerable assistance to all engaged in this class of work.

ROENTGEN RAYS.

ROENTGEN RAYS ACT STRONGLY ON THE TISSUES.

BY PROF. ELIHU THOMSON.

In some notes on Röntgen rays,[1] I have referred to an experiment made to determine the truth in regard to the effect which it had been claimed was produced locally upon the skin and tissues of those subjected for a prolonged period to the radiation from a Crookes tube. I noted the fact that after exposing the little finger of my left hand for half an hour close to the bulb, and about one and a quarter inches from the bombarded platinum, no decided effect followed until over a week; that the finger then reddened, became extremely sensitive, swollen, stiff, and to a certain extent painful. A slight blow or pressure would produce sharp burning pains.

I wish to add that at present, about seventeen days have elapsed since the exposure, and the finger is still quite sore, but showing signs of improvement. Two-thirds of the exposed portion is covered by a large blister which becomes larger each day. The pain and sensitiveness is less after the blistering takes place. The effect has not extended through the finger, but is confined to the back and sides, and is strictly limited to the exposed portion. Curiously, the skin over one of the joints of the adjoining finger, less exposed to the rays, became red and sore, but has become nearly normal without blistering, while a portion of the second finger on the side toward the source of radiation was reddened, but made only slightly sore and for but a short time only.

There is evidently a point beyond which exposure cannot go without causing serious trouble. It may also be that several shorter exposures would have an equal effect if made within a few days. The effect on my finger was made in a single exposure of half an hour at short distance, and by the law of inverse squares would be the same as from ten to twelve hours at six inches distance.

I do not think that the effect is electrostatic at all, as has been suggested, a view which I was at first inclined to favor, but the effect produced on the adjoining fingers which were further from the tube than the small finger and were electrostatically shielded by it, negatives the electrostatic theory. The evidence, so far as it goes, leads me to think that the effect is another indication of the chemical activity of Röntgen rays, of like character to the effect of the high pitch waves of light in causing sunburn, but penetrating more deeply into the tissues.

It remains to explain the long "period of incubation" which is peculiar, and is akin in effect to the well known period of incubation in various affections due to disease germs. Here might be the place to issue a caution to experimenters; it is: Do not expose more than a finger; be satisfied with the effect of, say, five hours' exposure at six inches distance, and do not prolong it to equal a longer time, or there may be cause for regret when too late. Personally, I have been quite more than satisfied with the results of my inquiry into the action of the rays on my own tissues.

FUNNY IDEAS ABOUT THE ROENTGEN RAYS.

Last week I was assisting at a large bazaar, says a correspondent of the London "Lancet," by holding a small Röntgen ray gallery, comprising a Crookes' tube, glowing, etc. As I in my temporary rôle of curator encountered many gems of exquisite unconscious humor, I venture to forward you a specimen or two as showing how a new-born scientific discovery is "understanded of the people." An elderly gentleman of prosperous appearance objected that the show was not "up to date," as he had "read somewhere in a newspaper that now you can see the liver palpitating and the heart circulating." Two elderly ladies entered the small room, and, solemnly seating themselves, requested me to close and fasten the door. Upon my complying, they said they wished "to see each other's bones," but I was "not to expose them below the waist-line," each wishing to view the apparatenly dismantled osseous structure of her friend first! A young and anxious mother asked me to see if her little boy had really swallowed a threepenny bit, as he was uncertain himself. She had read in the papers that a great doctor, Sir Something Blister (fact), in a speech in a large meeting in Liverpool a little while ago, said that a half-penny had been seen in a boy's "sarcophagus!" A young girl of the domestic servant class, taking advantage of her opportunity, as she thought, and my sex, asked me in confidence if I would "look through her young man unbeknown to him while he looked at the picture, to see if he was quite healthy in his internals."

MECHANICAL.

ECONOMIZER TEST OF THE HOLYOKE, MASS., STREET RAILWAY POWER STATION.

BY SAMUEL M. GREEN.

I HAVE been interested in the paper by Mr. Richard McCulloch on "The Modern Power House," read before the American Street Railway Association, and in connection with it I have thought that the results of a recent test which I have made upon an economizer at the power house of the Holyoke Street Railway Company may be of some interest to your readers. The object of the test was to determine whether or not the economizer, under the conditions existing at this plant, could be considered a financial success.

The plant consists of three 200 h. p. Babcock & Wilcox boilers, each containing 2,059 square feet of heating surface, three 400 h. p. Greene tandem compound condensing engines 15-inch and 28-inch x 48-inches, three independent Deane vertical fly wheel air pumps and condensers, two Deane duplex boiler feed pumps, an induced mechanical draft apparatus consisting of two fans 96 inches in diameter, and two double vertical inclosed engines 6 inches x 5 inches, and a stack 72 inches in diameter and extending 46 feet above the grate level.

The feed water passes first through primary coil heaters, each containing 135 square feet of heating surface, through which the main engines exhaust to the condensers, then through a secondary coil heater containing 500 square feet of heating surface, and into which the condensing pumps, boiler feed pumps, and fan engines exhaust; then through a Greene economizer consisting of 288 tubes and containing 3,350 square feet of heating surface, and having a storage capacity of 2,000 gallons. With the present average output at the plant it is not necessary to use the fans as the stack gives sufficient draft, although its force is very small.

TEST OF HOLYOKE STREET RAILWAY POWER STATION, NOV. 11, 1896.

Average temperature of flue gas at boiler	387°
Average temperature of flue gas at stack	246.6°
Average temperature of feed water entering	44°
Average temperature of feed water in primary heater	101°
Average temperature of feed water in secondary heater	207°
Average temperature of flue gas in economizer	246.2°
Draft at boiler, inches of water	.08"
Draft at stack, inches of water	.10"
Coal consumed	10,100 lbs.
Combustible consumed	9,995 "
Ash	805 "
Water evaporated	99,197.5 lbs.
Water evaporated per pound of coal	9.82 "
Total watt hours	2,965,000
Average watts per hour	157,461.0
Average electric h. p. per hour	212.08
Duration of run	18 hrs. 50 min.

It will be seen by the results of the test given above that the water is being delivered to the economizer at an average temperature of 207 degrees F. With this temperature in the secondary feed water heater there was almost no escape of steam from the heater, showing that the heat in the exhaust from the air pumps and boiler feed pump was practically all being returned to the boiler. The results show that the economizer is certainly utilizing the heat in the waste gases to a very large extent, and that a saving of about 3½ per cent is being effected. This saving upon the amount of coal at present consumed amounts to about $210 per year, or about 6 per cent. upon the capital invested in the economizer. If, however, the plant were running at twice its present output, the return upon the invested capital would be 12 per cent. at least, and it would probably be even larger, as the gases from the boilers would be hotter, and the resulting temperature of the feed water somewhat higher. The load at this plant is exceedingly variable, one engine carrying it during most of the run, but at certain times during the day two have to be used. This necessitates keeping one fire banked ready for use at a moment's notice. With this considered, I think the showing very creditable.

The feed water was measured by a Worthington meter which had recently been calibrated.

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—VIII.

BY LIEUT. B. A. FISKE, U. S. N.

THE service trials held with instruments in the U. S. flagship San Francisco for one year and subsequently in the U. S. S. Cincinnati for four months were satisfactory; and the system is now installed on a comprehensive scale in the battleships Maine, Texas, Indiana, Massachusetts and Oregon, and is about to be installed in the armored cruiser Brooklyn and the battleship Iowa.

Resistance of each galvanometer, 60 ohms.

Weight of each galvanometer, 22 lbs.

Diameter of each galvanometer, 10 inches.

Resistance of each transmitter box about 3.7 ohms, the wire being 22 gauge.

Resistance of each receiving box about 17 ohms, the wire being 26 gauge.

Sticking of the Galvanometer Needles.—This is not likely where instruments are run from a dynamo current, because the fact that a dynamo current is not uniform, but pulsating, gives the needles a minute vibration, which shakes them on the pivots and antagonizes any tendency to settling at one position.

In case a galvanometer does stick, however, the sticking will be due probably to one of two causes; first, the needle may stick on its pivot; second, there may be a little dirt, specially iron filings, attracted by the magnet, between the moving bobbin and the poles of the magnet between which it moves. Either one of these contingencies is improbable, if the instruments have been carefully tested after installation and then closed tight. But in case the needle does stick, the second trouble is the more probable one. The best way to hunt for it is to take off the cover of the instrument and hold an incandescent light so as to illuminate the interior, assisting the illumination by placing a sheet of white paper behind the moving coil. Any dirt can then be seen, and can be removed by a fine magnetized steel wire used as a probe. In case this annular space is clear, the difficulty will probably be in the pivot, and caused by the loosening of the little screws which adjust the pressure between the conical ends of the steel pivot and the agate bearings in which it rests at each end. The steel pivot ought to rest loosely, that is, not tightly, between its agate bearings, and the correct adjustment is made in manufacture and the adjusting screws are supposed to be set up tight, so as to prevent disadjustment. But in case the adjusting screws become loose, they must be reset. The only way is to tighten and loosen, carefully and by slow steps, until an adjustment is secured, such that the needle does not stick in any position.

Notes.—In the actual installation of the helm indicator and steering telegraph, each galvanometer of the helm indicator circuit is placed close to a galvanometer of the steering telegraph circuit; and both galvanometers are lighted from the electric light circuit and from the same rheostat, though in cases where the use of rheostats is inconvenient, small lamps using the full voltage of the light mains may be employed. In the case of the transmitter galvanometers of the steering telegraph and the receiving galvanometer of the helm indicator circuit, which are placed near them, the connections for their lights may be taken from the same rheostat as is used for the transmitters themselves, as shown in Figs. 7 and 8, the lights being connected to the binding posts, bc and cd, respectively.

The same arrangement may be used for connecting the range indicators to the electric light mains of the ship, and for lighting them.

Regarding the external resistances for the helm indicator and engine telegraph circuits, which are preferably placed in series with the circuits, as shown in Figs. 1, 10 and 11, it is sometimes better to use two equal resistances instead of one for each circuit, one resistance being connected to the positive light main, and the other to the negative. The reason is that in many ships, the light mains are connected together through two lamps which are in series with each other, and the wire joining the two lamps is connected to ground, the arrangement forming a "ground detector" The two mains become thus forty volts above and forty volts below "ground," respectively (supposing the total voltage to be eighty) If, therefore, two equal rheostats are employed, the helm indicator and engine telegraph circuits themselves will never be more than about two volts from "ground," so that the chance of a "ground" in either circuit is extremely small. For the same reason it is better, in the case of the steering telegraph circuits, to connect the transmitters to binding posts h f. Figs. 7 and 8, which are about midway between the two ends of the rheostats and at nearly zero potential or "ground."

All of the ship telegraphs and their lamps can be run, if desired, direct from the electric light mains of the ship without the introduction of any external resistance in their circuits, as it would be merely necessary to design them for the full voltage of the ship. But in view of the difficult conditions of ship life, especially in avoiding leaks and "grounds," it is thought that the low voltage system is the safest. The galvanometers may be made of convenient sizes for special installations.

If the radius of the wire of the transmitter of the helm indicator circuit is as great as 22 inches, the length of wire swept over by the traveling contact is sufficient to give the requisite deflection of the galvanometers, without using too great a current in the transmitter wire or too weak a spring in the galvanometers. It is safer, therefore, where the necessary space can be obtained, to use a radius not less than 22 inches.

THE LIGHTING OF THE TONAWANDA FURNACE BY PRESIDENT-ELECT McKINLEY.

THE promised revival of business and returning prosperity predicted upon the triumph of sound money in the late election, has not been long in manifesting itself. Indeed, the day after election the wheels had begun to turn in establishments which had stood idle for months, and with them thousands of hands resumed their wonted and longed-for activity.

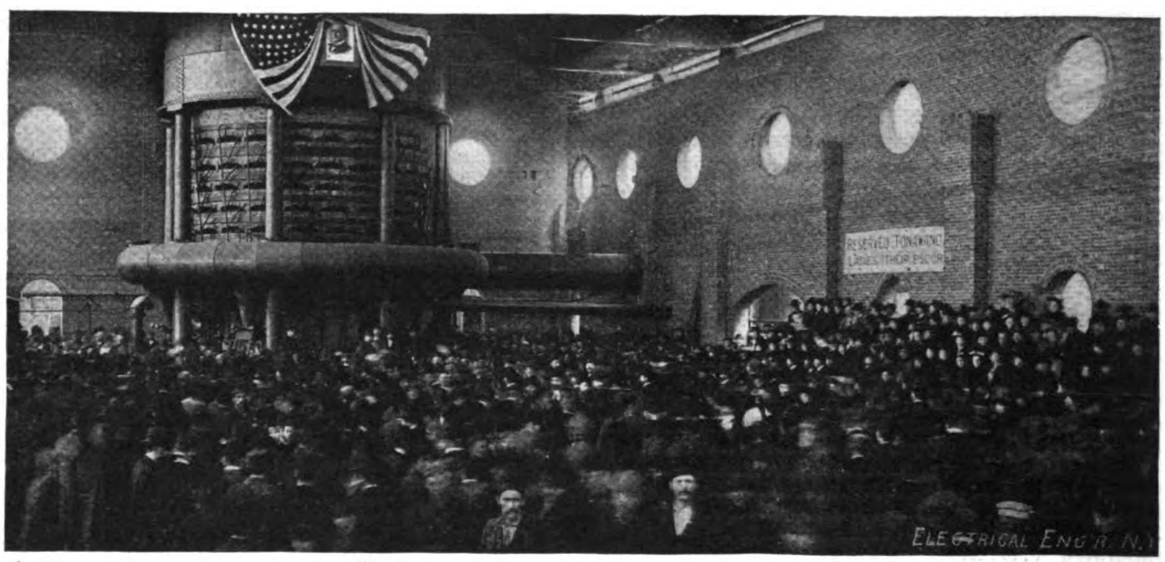
Among the establishments which had thus awaited the signal of advance was the Tonawanda Iron and Steel Company, of North Tonawanda, N. Y., whose new furnace, built at a cost of $250,000, had never been blown in, though completed several months ago. The result of the election, however, led to the determination to put the furnace in blast at once, and to emphasize the inauguration of the new era of prosperity, Maj. McKinley was asked to start the fires by electricity from his home in Canton, O.

To carry out this, the following simple means were adopted: There are seven tuyere openings about the hearth of the blast furnace, through which air is blown, and in lighting the furnace it is necessary to have it evenly lighted all around. Wires were strung around the bosh of the furnace, with an incandescent lamp opposite each one of these tuyere or blast openings. The upper part of the glass bulb of each lamp had been cut off, leaving a little cup around the socket, which was filled with gunpowder that piled up around the filament, so that when the current heated the filament the powder ignited; this, in turn, lighted cotton waste saturated with kerosene that was suspended over the bulb; the waste led into the interior of the furnace where about ten cords of wood and probably 1,000 tons of coke had been placed.

The Western Union Telegraph Company very generously gave the use of the wire free of cost from Maj. McKinley's home, at Canton, to the furnace itself. A dynamo was in operation at the furnace, so that when Mr. McKinley, at 3:30 p. m., November 5, touched the key at Canton, it completed a circuit between the dynamo and the wires around the furnace, which lighted the furnace in the manner above outlined.

This is the first time a furnace has ever been lighted in this manner, and some of the visiting iron manufacturers predicted a failure, but in every detail it was a complete success. The furnace was fired at every opening, connections were immediately made with the blowing engine, air was turned on and the owners state that the furnace started in better shape than they have ever seen a furnace start before. Since then it has been doing excellent work. The first cast was foundry iron, which is something unusual, as the first cast of a new furnace is expected to be poor.

The ceremony was witnessed by over 5,000 persons, and our engraving gives a view of the furnace as the crowd was beginning to gather. We are indebted to Mr. W. A. Rogers, president of the Tonawanda Iron and Steel Company, for the above details of this interesting event and for the photograph reproduced in the accompanying illustration.



FURNACE AT NORTH TONAWANDA, N. Y., LIGHTED BY PRESIDENT-ELECT MCKINLEY FROM CANTON, OHIO.

EXPERIMENTS WITH INCANDESCENT STREET LIGHTING IN DENVER, COLO.

DENVER is one of the cities that has had experience with street lighting by means of incandescent lamps, and we are indebted to Mr. John H. Poole, general manager of the Denver Consolidated Electric Company, for a statement of some of the results. He says: "We put in originally what is known as the Edison municipal system for street lighting. We installed in this city about 1,200 of these lights. Soon after this installation a demand for the replacement of these lights by arc lights in the business section was begun, and a gradual displacement of the entire system followed. This was all in deference to the public demand for arc lights which seemed to give much better satisfaction. Unquestionably they furnish a great deal more light for the same amount of money. The direct loss to this company was in the neighborhood of $100,000. This was due in part to the continual changes and re-arrangements of lines necessitated, and to the ultimate loss of all the machinery, wire, posts and fixtures. We put in originally also a number of towers, which were subsequently removed, in accordance with the popular demand, involving a still further absolute loss to the company. We now have arc lights suspended from the intersection of streets, and they seem to give general satisfaction to our citizens. All the changes above referred to were made in compliance with the public wish, and not in accordance with our own, as we were not only put to the complete loss of the old system, but the expense of installing a new one. We say, therefore, without hesitation, that the preference of the people in Denver is decidedly for arc lights." This will be interesting data for St. Louis, where it is now proposed to substitute incandescents for arcs on the streets.

PERFORMANCE OF THE THOMSON WATTMETER.

Our readers will recall recent correspondence carried on in our columns between Mr. Milne and Mr. C. D. Haskins regarding the merit of the Thomson recording wattmeter. We learn that within the past month a series of important tests have been made to determine the accuracy of the meter in question under certain conditions. The tests were carried out to verify sundry criticisms to the effect that on rapidly fluctuating loads the meter was derelict in its accuracy, especial reference being had to elevator work.

The object of the tests was the determination of the mean error under maximum conditions of fluctuation and the result was gratifying from the standpoint of the meter. It was found that the maximum of error, introduced by this character of load—that is, under the worst possible or maximum condition of fluctuation, did not exceed sixth-tenths of 1 per cent., a percentage materially reduced under conditions less than the maximum.

NEWCASTLE, England, is to have an electrical and engineering exposition next year in commemoration of the Queen's long reign, surpassing in length that of any other English sovereign. It will be international in character.

THE JACQUES CARBON GENERATOR.

MUCH has been written of late about the invention recently patented by Dr. Jacques, of Boston, by which it becomes possible to obtain electricity directly from coal; and while Dr. Jacques has been widely complimented on his discovery and the highest scientific authorities who have examined it have been enthusiastic in their praise, there has been, as might naturally be expected in an invention of this importance, some unfavorable criticism based upon alleged misconception as to what the invention is and a lack of published data as to its capabilities.

In a letter published in The Electrical Engineer, of July 22, 1896, Mr. C. J. Reed said that it seemed to him evident that the electrical energy derived from the Jacques cell or generator, instead of being evolved directly from the carbon, was produced by a thermo-electric junction. In the "Journal of the Franklin Institute" for July, there appeared a paper communicated by Mr. Reed to the Institute, concerning a method of his own for deriving current from coal, though indirectly, and this is reported in the same journal to have been followed by certain experiments with "an extemporized Jacques cell," by which he sought to show that the consumption of carbon, or even its presence, was not at all essential to the operation of the cell.

These assertions of Mr. Reed, and the accounts of the experiments referred to, have been very widely copied and commented upon. Further criticisms have been made by various writers, that such reports of the efficiency of the Jacques process as have been published are based upon the amount of carbon consumed within the pots, and no data is given as to the amount of coal consumed upon the grate or the power necessary to run the air pump—factors which evidently might greatly modify the commercial efficiency of the apparatus when put into use.

Up to the present time no authoritative reply to these various criticisms has appeared. But in the Christmas "Harper's Magazine" we find a most interesting article by Dr. Jacques, in which the whole story of the invention is told; and these various criticisms, although not especially mentioned, seem to be effectually answered, as the following extracts show:

"That the electric current was due to the chemical combination of the oxygent of the air with the coke (carbon) there could be no doubt. Quantitative tests showed that oxygen was taken from the air; that the carbon was consumed; that carbonic acid was formed. Moreover, the electromotive force obtained agreed almost exactly with that which is theoretically obtainable from the combination of oxygen with carbon to form carbonic acid (1.04 volts). That the phenomenon was not due to thermo-electric action was proved by the fact that when the whole apparatus was so inclosed that all parts were kept of uniform temperature the maximum electromotive force and current were obtained. Again, later experiments with far larger apparatus have not only confirmed these results, but have shown that under proper conditions the electrical energy obtainable from one of these generators is substantially equal to the potential energy of the weight of carbon consumed within the pot."

The remaining criticisms would seem to be abundantly answered and the commercial aspect of the invention shown by the following extract: "As compared with modern steam engines, only relatively small carbon electric generators have as yet been built; and it should be remembered that with this generator, as with the steam engine, increased size means increased efficiency per pound of coal, particularly in the coal consumed on the grate. Following, however, are some results of a test (made by experts not connected with the development of the invention) upon a small and comparatively crude 2 horse-power carbon electric generator that has been in occasional use for some six months:

Average electrical horse-power developed	2.16	h. p.
Average electrical horse-power used by air pump....	0.11	"
Average net electrical horse-power developed.......	2.05	"
Carbon consumed in pots per electrical h. p. hour....	0.223	lb.
Coal consumed on grate per electrical h. p. hour......	0.336	"
Total fuel consumed per electrical h. p. hour....	0.559	"
Electricity obtained from 1 lb. of coal (of which 0.4 lb. was consumed in the pots and 0.6 lb. was burned on the grate)......	1,339	watt hours

or 32 per cent. of that theoretically obtainable.

"Thus the efficiency of this particular generator was twelve times greater than that of the average electric light and power plant in use in this country, and forty times greater than plants of corresponding size.

"There are, however, many details still to be worked out, and many improvements yet to be made, before the carbon electric generator can be put into general commercial use on a scale comparable with that of modern steam engines."

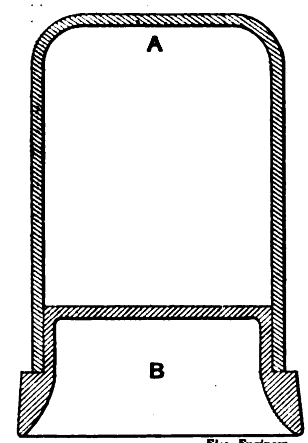
We need scarcely say that the figures given by Dr. Jacques will be welcomed by many who have heretofore looked askance at the Jacques generator for want of data regarding its performance. Even though the generator consumes 50 per cent. more coal on the grate than was absorbed in the purely electrical work, the results are, nevertheless, gratifying and may well encourage Dr. Jacques in pushing still further toward perfection. The "electricity direct from coal" problem is the most important one on the tapis at the present time and we are reliably informed that a scientific syndicate, if we may so term it, is at work at it in the the United States.

WEATHER-PROOF APPARATUS.

BY CHARLES WIRT.

BEING of the opinion that much has yet to be learned regarding the best methods of weather proofing apparatus intended to be exposed out-doors, the writer wishes to describe a somewhat peculiar performance of the weather proof casing of a lightning arrester. The accompanying cut shows the casing in section. The cover A being a bell shaped, solid drawn brass shell, fitted over the base plate B, which was turned to give a good, easy fit. The cover being in one piece and seamless, it was considered that with a rather long and well-fitted joint, this case would be above suspicion as to weather proof character. After extended experience, however, a few cases were found where water had undeniably found its way into the interior. That this had occurred, was at first hard to believe, but like the case of the man who "could not be put in jail," and was already locked up, the water was there, in very small quantity, but not to be disputed.

After some speculation, a reasonable solution was suggested,



SUPPOSED WEATHERPROOF COVER.

which is, no doubt, a correct one. The joint, although closed and mechanically good, was, of course, not air-tight, and the temperature variations occurring from day to day, and from hour to hour, would, of course, expand and contract the contained air, causing a slight, but appreciable, transfer of air from inside to outside with a rise of temperature, or from outside to inside with a falling temperature. In case of a shower, a film of water would cover the lip of the casing where it meets the shoulder of the base plate. This would form a complete water seal, and on contraction of the air inside, as would be most likely to occur from the fall of temperature usually accompanying such a shower, this film of water would be drawn into the interior. With a badly made joint, or one having somewhat irregular contact between the parts, this trouble could not occur, as a water seal cannot be made to fill more than a very small space.

In this connection a mistaken idea, and a very common one, regarding protection against weather and damp, might be alluded to. This is the idea: That damp can be excluded from the interior of a box or case by any kind of seal, which is not absolutely air-tight. An incandescent lamp might be considered as a good example of an air-tight receptacle. It is evident on reflection that variations in pressure continually occurring in the atmosphere will cause air to enter and leave any closed space, unless such space is sealed in such a way as to resist the pressure changes. Consequently the interior of such receptacles not hermetically sealed will represent the average humidity of the external atmosphere, the interior changes in humidity being less rapid and less extreme than the changes in the surrounding air.

CONTENTS.

COMPRESSED AIR.—A CRUCIAL TEST.

FOR some time past the engineering world has been put on the qui vive by the advocates of compressed air, who have with assiduity sought to prove that this agent is more economical as a power-transmitting medium than is electricity, not only for the operation of stationary motors of all kinds, but for railway cars as well. We have no fault to find with the honest convictions of any one, but unfortunately for our compressed air friends, the works of daily practice are the best evidence that it is a delusion which has taken hold of them. By this we do not mean to imply that there are no uses for compressed air; quite the contrary. We believe and are convinced that for many purposes, too numerous to mention here, compressed air, as such, but not as a substitute for electricity, has a wide field open to it. Nor are we unmindful of the fact that under certain conditions compressed air may have collateral advantages which may in certain cases involving ventilation and fresh air supply make it preferable to electricity.

The limits of successful compressed air transmission as compared with electric transmission have been the subject of numerous essays from the highest authorities in engineering, and the question is now to be found discussed in all text books on the subject, so that it is not necessary for us to go into detail. But an actual example is worth a volume of theorizing, and we are fortunate in being able to present in this issue an authentic account of a comparative test between the two forces under discussion. This test, carried out by Mr. Lewis Searing, a well-known Western mechanical engineer, showed that the total efficiency of a compressed air mine pumping plant was only 9 per cent.; that is, it took 312 horse-power at the steam cylinders of the compressors to do the work equivalent to 28 horse-power as measured by the amount of water pumped against a given pressure. The electric plant installed accomplished similar work at an efficiency of 44 per cent., notwithstanding the fact that both the dynamo and motor were underloaded.

So far as the efficiency of the compressed air plant is concerned, we must confess that we are not surprised at the result, when one considers the length of transmission. What with the loss in compression, leaks at joints and loss of pressure due to friction in the pipes, together with the low efficiency of the compressed air pumps, the wonder is that the showing was as good as it turned out to be. It may be objected that it is hardly fair to single out an exceptional case like this and hold it up as a basis for the general condemnation of an entire system. Such is not our intent. What we desire to emphasize, however, is our belief that few compressed air plants can to-day stand a rigorous comparative test with electricity without showing such a decided difference in favor of the latter that further operation by air would be considered disadvantageous.

The tests of Mr. Searing also throw some light on what may be expected from compressed air as a motive power for street cars. True the conditions are not absolutely identical, but the only essential difference is the absence in the case of street cars of the connecting pipe between the compressor and the air motor on the car. We leave it to our readers to make their own conjectures as to the allowance to be made for this difference and to calculate how much would have to be added to the 9 per cent. efficiency of the pumping plant to compensate for the removal of the connecting pipe.

NIAGARA POWER IN BUFFALO.

SOME weeks ago we illustrated and described all the features of the pole line and circuits for the Niagara transmission to Buffalo, and we are now able to give, again for the first time, the full details of the apparatus used at both ends of the line, for stepping up the current and then for stepping it down and changing it to direct. All these details will be found full of interest, especially in view of the fact that on

Wednesday last the current was actually thrown into the street railway service and used for operating the cars.

We shall soon be able to see how the new power in Buffalo is able to compete with the old sources of supply in coal and natural gas. If the figures given in Buffalo be correct, steam power there to-day, with coal at $2 per ton, is costing on lots of 50 horse-power, ten hours daily, about $55 a year per horse-power. Against this may be put the charge to the Buffalo Street Railway of $40 per year, per horse-power, 24 hours daily, for the first 1,000 horse-power and $36 per horse-power for that subsequently taken. Even putting the steam power on the larger basis, there would seem to be no comparison, and to small power users the saving would appear to be as large as it is to concerns taking the Niagara power in big blocks. The working out of these conditions will be of great interest. To-day Niagara Falls has become part of the resources of Buffalo, and nothing can stand between that city and its great future.

It will not be forgotten that the 35-mile San Joaquin-Fresno plant is in operation. Moreover, as we go to press, a terse communication reaches us from Mr. T. A. W. Shock, general superintendent of the Sacramento Electric, Gas and Railway Company, reminding us that he has been transmitting power 22½ miles, from Folsom, for a year and a half, for light and power, and for operating 22 miles of street railway. "Not a night goes by but that our load runs from 1,800 to 2,000 horse-power, so that the transmission of 1,000 horse-power a distance of 22 miles is not an experiment but an assured fact." The honors, therefore, still seem to rest with Mr. Shock, whose results are full of encouragement to his Eastern rivals in this power transmission.

STANDARD REQUIREMENTS FOR INCANDESCENT LAMPS.

THERE is perhaps no more vexatious question which the central station manager has to deal with than the procuring of proper incandescent lamps for his circuits. When he purchases a dynamo or a motor or a transformer, a test extending over an hour or two enables him to determine whether the manufacturer has lived up to his guarantees, but in the case of the incandescent lamp nothing short of the actual running of the lamp for the larger part of its life can indicate its true worth. How to remedy this evil must no doubt be a subject of frequent cogitation with large consumers of incandescent lamps. Other questions, relating to this subject, such as the standardizing of the bases, are beginning to receive proper attention, but the most vital of all, it seems to us, namely, the formulation of a standard of life and efficiency, has still to receive its due recognition. But while Americans are still haggling over lamp bases, our German cousins have gone at the more vital question above referred to and some time ago the Verband Deutscher Electrotechniker appointed a commission to investigate the subject and submit a set of standard rules and regulations for the guidance of all interested in the handling of lamps, whether as consumers or manufacturers. This commission, on which both makers and users were represented, has drawn up its report which will be submitted at the next annual meeting of the Verband, and as it touches a question which must sooner or later come up actively in the United States it may be well to point out in brief the salient points of the proposed standard requirements. The latter, among other things, permit of a variation of 2 per cent. in the voltage marking of lamps ordered, the lamps to be tested at the voltage marked on them. A variation of 6 per cent., either way, in candle power or energy consumed, is allowed; but if more than one-fourth of the lamps tested exceed these limits, the whole lot may be rejected.

The standard of life of the lamp is taken to be the number of hours at the end of which the lamp has lost 20 per cent. of the candle power marked on it when running at its normal potential. Other clauses of the regulations refer to the submission of disputes to third parties, the court of last resort being the Physikalische Reichsanstalt in Berlin. No claims can be made after 30 days and then only, when 2 per cent. of the lamps remain untouched and available for test. The minimum number of lamps in any event must be 20.

We note also that the commission recommends the adoption of the Edison lamp base for general introduction, a step which will probably not be without due influence on the action of the committee of the National Electric Light Association now engaged in investigating this particular question. It is a pity, indeed, that the American Committee's work should be so limited. Not that the lamp base matter is of small importance, but the whole question of the incandescent lamp as regards the relations between manufacturer and user is still in such a chaotic state that it is high time order were brought out of it. Now that both sides have got together on the lamp base, would it not be just as well for them to extend their labors and settle once for all a matter of paramount importance to the whole industry? We would suggest that President Nichols, of the National Electric Light Association, could in no better way insure the permanent fame of his tenure of office so auspiciously begun, than by bringing about so desirable a result.

SOCIETY AND CLUB NOTES.

MR. JOSEPH SACHS ON HORSELESS CARRIAGES.

A very interesting and instructive lecture on the subject of "Horseless Carriages" was delivered before the New York Electrical Society on Nov. 19 by Mr. Joseph Sachs, who also repeated the lecture in a more popular form before the Henry Society on Nov. 20. The lecturer traced first the history of the subject, dwelling upon the growing importance of transportation, and then showed how, within the past year or two, experiments of the earlier inventors had now crystallized into definite types. He divided horseless carriages into three main classes—steam, gas and electric—and then suggested that these also had their subdivisions according to the service required. It was pointed out that the question of motive power was but one among many, the others dealing with the design of the body, steering, gearing, controlling apparatus, attendance, cost of operation, facility of renewing supplies, speed, grade climbing ability, weight, comfort, safety, etc. All these considerations were rapidly touched on in the review of the various types of carriages, a large number of which were illustrated in perspective and by diagram. Mr. Sachs had on exhibition, to illustrate his remarks on the electric carriage, two of the small Riker motors that have been so successfully employed in this class of work. Mr. Sachs said that in every respect the electric carriage of to-day was at once ideal and practical—as a carriage—but he thought much improvement was still desirable and possible as to the batteries or source of current.

LETTERS TO THE EDITOR.

A PROPHECY AS TO THE BERLINER SUIT.

The lucubrations of some of your contemporaries who have law departments as sideshows have always been entertaining to the "profesh." They all shoot wide of the mark in the Berliner business, or rather, they shoot very large charges of very small missiles, and as a consequence bring down nothing.

I venture to say that the Berliner patent suit now before the Supreme Court will be disposed of on these legal propositions only and the suit dismissed.

No granting power, kingly or otherwise, is given to canceling grants made with due deliberation and in due form, especially where that grant has the sanction of a statute, excepting upon one or two grounds, to wit: First, That the grant was obtained by fraud or misrepresentation of the grantee. Second, That the grant was made in ignorance of the equitable rights of others upon whom the grant is found to work a gross hardship or injury and that no legal machinery exists to cure the mistake.

The court will not find for the government on either of these propositions, and as to the other points, that there was no invention or that the application hung a long time in the Patent Office, or that the Commissioner was mistaken in his judgment upon the subject of the introduction of new matter into the application by amendment and otherwise, it will hold that the statutes provide for an inquiry, (when an inquiry is admissible), in a different kind of suit. B. S.

New York City, Nov. 19, 1896.

Power Transmission.

INAUGURATION OF THE NIAGARA-BUFFALO POWER TRANSMISSION.

BY ORRIN E. DUNLAP.

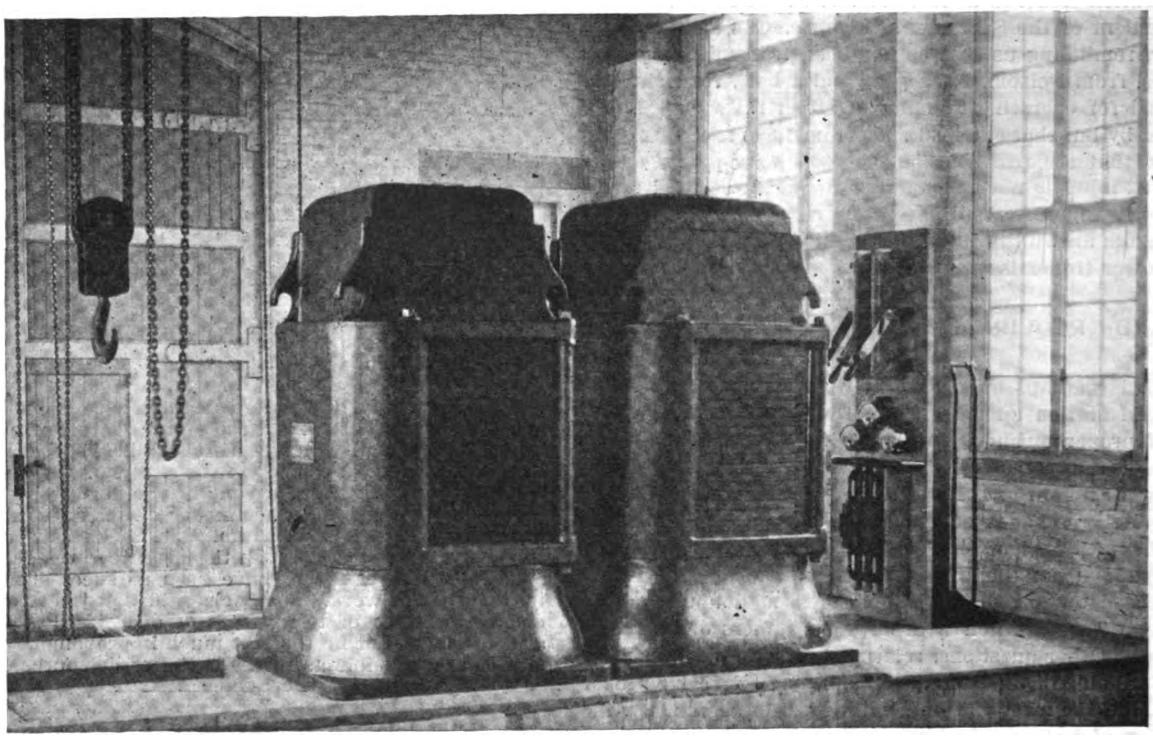
THE greatest event in the history of the power development at Niagara Falls occurred at 12:01 o'clock on the morn- of Monday, November 16, when Mr. William B. Rankine, secretary of the Niagara Falls Power Company, threw the switch that sent a portion of the power from one of the huge generators into the transformer house, adjoining the power station, where it was passed through transformers and transmitted to Buffalo.

A few minutes before midnight Secretary Rankine, William A. Brackenridge, M. Am. Soc. C. E., chief engineer of the Cataract Construction Company, and Paul M. Lincoln, electrical superintendent of the Niagara Falls Power Company, mounted the switchboard platform, and at one minute after midnight Mr. Rankine threw feeder switch No. 4 releasing the power into the transformer house, where Mr. J. R. Edmonds, the Niagara Falls representative of the General Electric Company, was on duty. He closed the high tension switches and connected the transformers to the line. The low tension switch was thrown and the current passed into the transformers and out over the line to Buffalo. Everything was found to be in perfect working order. At the Buffalo end of the line, in the Buffalo Street Railway Company's plant, were gathered Mr. W. L. R. Emmet and Thomas H. Fearey, of the General Electric Company; George Urban, Jr., president of the Cataract Power and Conduit Company; Edgar B. Jewett, mayor of Buffalo; H. H. Littell, general manager of the Buffalo Street Railway Company, C. R. Huntley and other men prominent in the affairs of that city.

The Niagara Falls Power Company's contract with the Buffalo Street Railway Company calls for the delivery of 1,000 horse-power at $36 per horse-power per annum. This power will be taken from the bus-bars into which the big generators feed in the power house.

In connection with this installation it may be stated that the General Electric Company entered into three separate contracts, and therefore three separate companies are interested in the apparatus installed. The first contract was made with the Cataract Construction Company. This was for three air blast transformers, blower motor, switchboards, etc. Each of these transformers is of 1,250 horse-power capacity, and any two of them can be used to transform 2,500 horse-power delivered to them in two-phase currents at 2,200 volts to three-phase currents at either 11,000 or 22,000 volts. In these transformers the coil connections are so arranged that the change in the voltage from 11,000 to 22,000 can be easily effected. Both the primary and secondary connections of the transformers lead to a switchboard. The low tension board is fitted with switches and fuses, while the high tension board is fitted with switches, fuses and current indicators.

Under their contract with the Cataract Construction Company the General Electric Company have installed the transformers with all cables, connections, etc., from the generators in the power house to the transmission line. Lightning arresters have been placed in a small building on the south side of the transformer house at the point where the cables leave the building. The third transformer furnished under this contract is held in reserve. The design adopted for the Niagara installation is such that it can be extended until the full capacity of the transformer house is reached. The transformers are each 7 feet 10 inches high, and measure 5 feet 4 inches by 4 feet 8 inches at the base. Each weighs about 25,000 pounds.



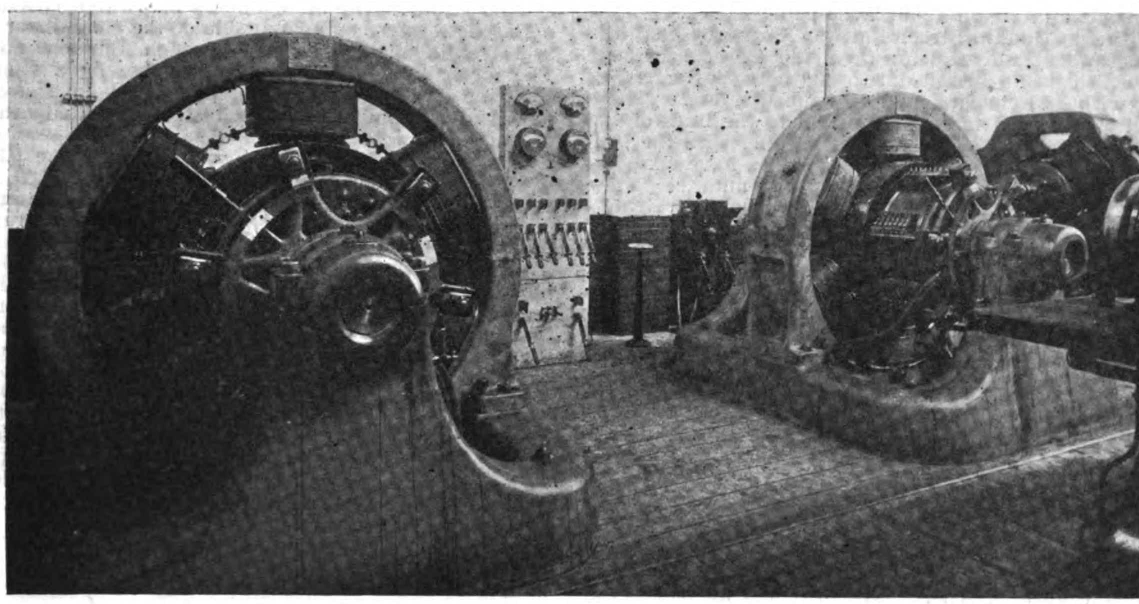
General Electric Step-Up Static Transformers in Niagara Power House.

The two transformers now in place stand at the eastern end of the transformer room and are supported on an iron framework, their bases being 8 feet below the floor of the transformer house. The space below them is practically an air-tight enclosure through which all connections to the transformers are made. In the pit below the transformers there is ample room for walking about, all conductors and connections being supported on large porcelain insulators and iron brackets. The connections to the transformers are made so that they can be detached without much trouble, and at any time when it is found advisable to substitute the extra transformer for one of those now in service, these connections will be opened and the transformers changed with the aid of a crane.

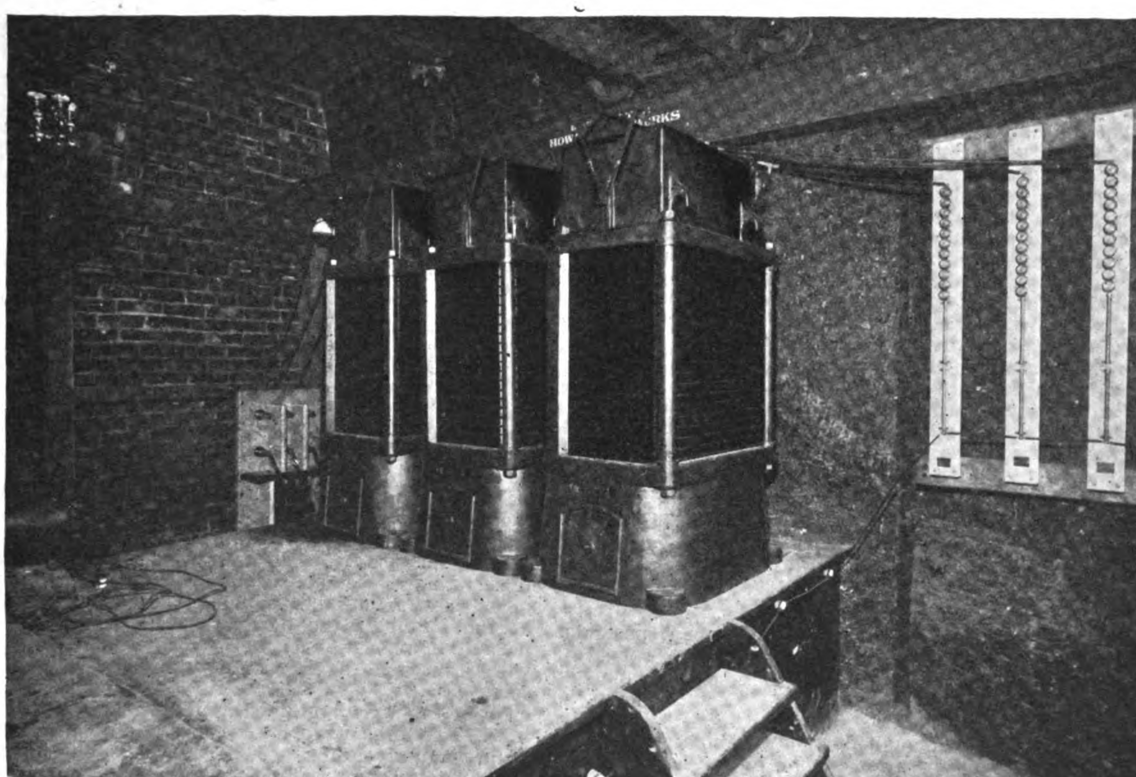
In the southeast corner of the transformer room stands a large centrifugal blower which is driven by a 5 horse-power electric motor, which stands close beside it. This blower delivers air to the enclosure below the transformers, from which point the air passes upward through spaces provided between the coils, and also by a separate space, provided between the laminations of the iron. The amount of air delivered in each of these places is controllable by valves, so that the tem-

perature can be suitably adjusted with the minimum load on the blower motor. The arrangement of coils in these transformers is such that very strong insulation will have to be punctured before connection can be made between the different coils, or between the coils and the iron. At the same time the air spaces are so placed that the air is brought intimately in contact with each coil and gives an excellent cooling effect. This method of cooling makes necessary the occupation of a good deal of space in insulation and air, which has a tendency to increase the size of each transformer. Still, it is very apparent that it has the very great advantage of making the transformer clean and accessible, and much more convenient to handle than a transformer cooled by other methods.

The second contract the General Electric Company entered into in connection with the Niagara-Buffalo transmission was with the Cataract Power and Conduit Company, of Buffalo. This company was incorporated July 17, 1896, with George Urban, Jr., as president, and they will be the distributing agents of Niagara power in the city of Buffalo. Among others interested in this last named company are William B. Rankine, D. Ogden Mills, John Jacob Astor, Edward D. Adams, Francis Lynde Stetson, E. A. Wickes and Daniel O'Day. Their contract with the General Electric Co. called for four 265 k. w., or 360 horse-power transformers to be used in reducing the current from the line to a voltage suitable for connection to 500-volt rotary converters. These transformers are installed in a special building connected with the Buffalo Street Railway Company's power house. Their general construction and the



THE GENERAL ELECTRIC ROTARY CONVERTERS IN POWER HOUSE OF BUFFALO STREET RAILWAY CO.



INTERIOR OF STEP-DOWN TRANSFORMATION ROOM, REAR OF NIAGARA STREET STATION, BUFFALO RY. CO.

method of cooling employed is very similar to that used with the large transformers at the Niagara Falls end of the line, described above. This building is also provided with switchboard and lightning arresters. The "step down" transformers are each 6 feet 10 inches high, measure 3 feet 11 inches by 3 feet at the base, and weigh about 7,000 pounds each.

It was with the Buffalo Street Railway Company that the third contract was made, and for them the General Electric Company furnished and installed two 500 horse-power rotary converters, with switchboard and instruments, etc. These rotaries will be operated to supply current to the lines of the Buffalo Street Railway Company, or in parallel with the generators now in their power house. The rotaries have six poles and operate at a speed of 500 revolutions per minute. They can be started either from the alternating current or by direct current from the lines to which they are attached.

It is significant of the enterprise of the Niagara Falls Power Company that they have built this transmission line and transmitted Niagara power to Buffalo at this early date, when their Buffalo franchise simply demands that they shall be prepared to sell power in that city on June 1, 1897. The erection of the line in the short period that has elapsed since it was started is work most creditable to all who had contracts. Especially is this true of the work of the White-Crosby Company, who built the pole line, and the General Electric Company.

At present three styles of insulators are on the line. The most noticeable of these, however, is the Niagara type, made by the Imperial Porcelain Works, of Trenton, N. J. The poles used in the construction of the line were furnished by Thomas Barnard, of Lockport, whose men cut about 1,500 of them on the Indian Peninsula, Georgian Bay, while about 1,300 of them were obtained at various points along the Canadian Pacific Railway.

The lightning arresters are of the Wirt type, single pole, and consist of marble upon which are mounted eleven cylinders giving one air gap space 1-32 in. for each one thousand volts with an allowance of 25 per cent., rise in the potential. In the action of the arrester the large metal cylinders serve to chill the arc so that on reversal of the current the arc is extinguished, no dependence being placed upon any non-arcing property of the metal to put out the arc. In order to limit the current on short circuit and thus the heating effect, a special solid graphite rod of low non-inductive resistance is used. The arresters are similar to those used on the Big Cottonwood transmission at Salt Lake City, described lately in The Electrical Engineer, which have effectually protected the machinery in many severe storms.

The first power sent to Buffalo was at a voltage of 11,000, and now that the line is in successful operation, it is probable that the news will soon come that Buffalo is prepared to use more power. The Buffalo franchise calls for the delivery of 10,000 horse-power there by June 1, 1897, should there be a demand for it, and also that the power company shall be prepared to supply 10,000 additional horse-power within each successive year thereafter for four years, as far as the demand may require. This would be a total of 40,000 horse-power, or the total product of eight generators at the Falls.

In preparation for an increased demand for power the Niagara Falls Power Company have decided to install five new turbines and generators in the wheel pit and power house extensions as soon as they are ready for them.

At a recent meeting the company received applications from tenants already on their lands for 5,000 additional horse-power, which is evidence that several of the firms now doing business there intend to enlarge their facilities.

ELECTRICITY VS. COMPRESSED AIR.—ACTUAL RESULTS IN A MINE OF THE COLORADO FUEL AND IRON CO.

BY LEWIS SEARING, M. E., E. E.

THE recent resurrection of compressed air as a possible rival of electricity as a motive power, makes a practical test of both systems under similar conditions of special interest.

Last year the writer was called upon to investigate the compressed air system in operation at one of the largest coal mines of the Colorado Fuel and Iron Company, to ascertain the possible saving that could be made by substituting electricity. The result of the investigation showed such a great possibility for saving by the use of electricity that the Fuel Company decided to have a plant installed. The installation was made under the personal supervision of the writer, and afterwards operated under his direction for over a month, during which time tests were made and the workings of both systems noted.

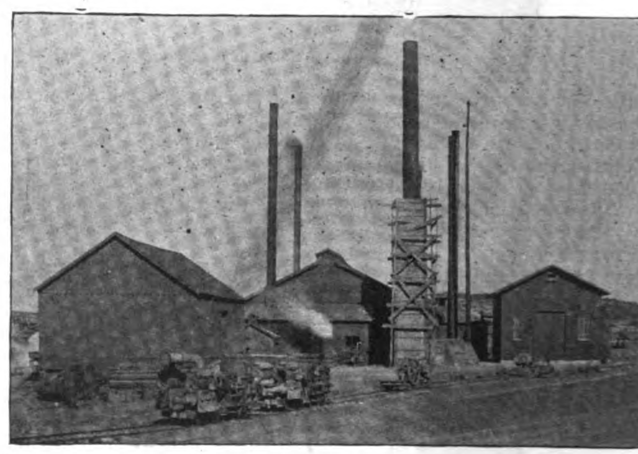
The above-mentioned mine is located at Rouse, Colorado, at an altitude of 6,000 feet. The compressed air plant was employed only for pumping and comprises three Norwalk air compressors, each with 13½-inch high pressure air cylinder, 22-inch low pressure air and 20-inch steam cylinder, all of 24-inch stroke. The air cylinders are water jacketed.

The air receiver stands outside of the compressor house, and is 4 feet in diam. by 12 feet high, having no covering. The air is conducted down No. 1 mine by a 4-inch pipe to a Deane duplex direct acting pump, 18½-inch steam by 9¼-inch water cylinder by 12-inch stroke, located near the face of the slope.

No. 1 mine enters on a slope of an average 5.3 per hundred, continuing downward a distance of 3,300 feet. The workings ramify from this main slope and connect with another mine, known as No. 3, in which there were two small pumps, operated by air. At the time of the test of the air plant these pumps were shut down.

Air is conducted to No. 3 mine by a 4-inch pipe down No. 1 slope about 1,400 feet, from which point a 3-inch and 4-inch pipe crosses to No. 3 through the interconnected workings. The compressors being 400 feet from the mouth of No. 1 slope, the total length of 4-inch pipe to the pump near No. 1 face is 3,600 feet. Pipe to No. 3 has 5,000 feet of 4-inch and 800 feet of 3-inch, a total of 5,800 feet. The air pipes are laid underground as far as the mouth of No. 1 slope, and from there continue down the mine unprotected.

The pump at the bottom of No. 1 slope, on which the test was made, discharged water to the surface through 700 feet of 10-inch pipe and 2,550 feet of 6-inch pipe, the pipe being laid up the slope in a practically straight line. The boilers



POWER PLANT, COLORADO FUEL AND IRON CO., ROUSE, COL.

supplying steam to the compressors consist of a battery of two 60 inches by 16 feet horizontal tubular and six plain cylinder boilers 36 inches by 36 feet, all of which are set in brick. The boiler and compressor house are adjacent to each other, making the connecting steam pipe comparatively short.

The test of the compressed air system was confined to the one pump in No. 1 slope, to obtain the total efficiency between the steam cylinders of the compressors and the water discharge of the pump. This test was not supposed to be an exhaustive one, but made simply to get a good estimate of the efficiency of the system. The amount of water discharged was measured by a weir at the end of the water discharge pipe on the surface. The weir was 16 inches wide, with measuring stake 4 feet up stream.

A pressure gauge was placed on the water discharge pipe at the pump at the bottom of the mine; air pressure was measured at the receiver. Crosby steam engine indicators were attached to the steam cylinders of the air compressors.

Observers were stationed at the various points to take readings. Readings were taken through the day, commencing at 10 a. m. and ending at 5 p. m. At one time in the afternoon one minute readings were taken for ten minutes. At another time one of the compressors was shut down and the pumping done by two compressors, as a check on the indicator measurements.

The results are somewhat surprising:

Average steam pressure	80 pounds
Average air pressure	50 "
Average revolutions per minute:	
Three compressors	64

Two compressors	110
Average gallons discharged by pump per min.	400
Average strokes of pump per minute	176
Average pressure per sq. inch pumped against	120 pounds
Average indicated horse-power at steam cylinders of compressors	312 h. p.

As the theoretical horse-power required to force 400 gallons per minute against 120 pounds is 28, it follows that the efficiency of the system between the points measured is less than 9 per cent!

It will be observed that this is the efficiency of the plant as found under actual working conditions, and includes every loss which may occur between the steam cylinders of the compressors and the water discharge of the pump, and due to wear of apparatus and to inherent and other defects in the system.

As there are many mines in the State that are forced to employ a similar method of pumping under similar conditions, it is fair to assume that the above given efficiency is not far from the average, and that nothing short of a change of system would make a material increase in the efficiency. If we go back of the steam cylinders to the coal pile, we find a still more deplorable state of affairs, for, to operate these three compressors requires eight boilers, consuming 35 tons of coal per day of 24 hours!

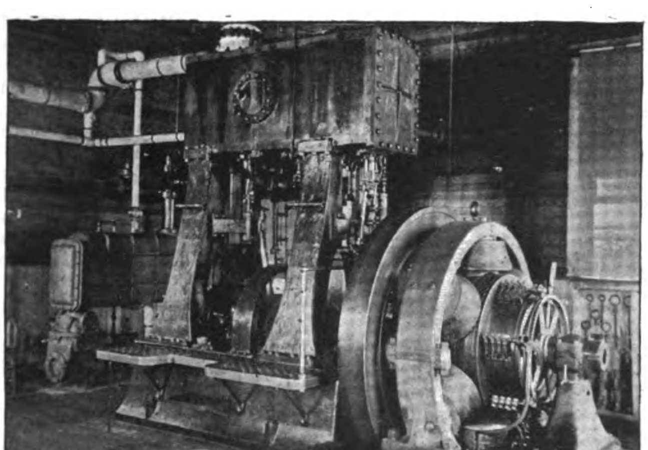
The probable efficiency of the electric plant was estimated as follows:

Direct coupled engine and generator	80 per cent.
Line	90 " "
Motor	85 " "
Pump and gearing	82 " "
Total efficiency	50 " "

With the above efficiency, a 60 horse-power engine would do the work now requiring 312 horse-power by the compressors. Further, assuming the installation of a compound engine, using the mine water for condensing, the total coal consumption per 24 hours would not exceed three tons, making a saving of 32 tons per day.

The order for the electric plant was given to the Denver Engineering Works Company, who were instructed to install sufficient power to operate, in addition to the regular pump, the ventilating fans, screens and shops about the mine, the selection of the machinery being left entirely to the engineers of the Denver Engineering Works. The plant as installed is as follows: The power house is a substantial building of wood, covered with corrugated iron and completely sealed inside. It is large enough for two generating units and condensers, and is equipped with a 6,000-pound capacity, three-motion traveling crane.

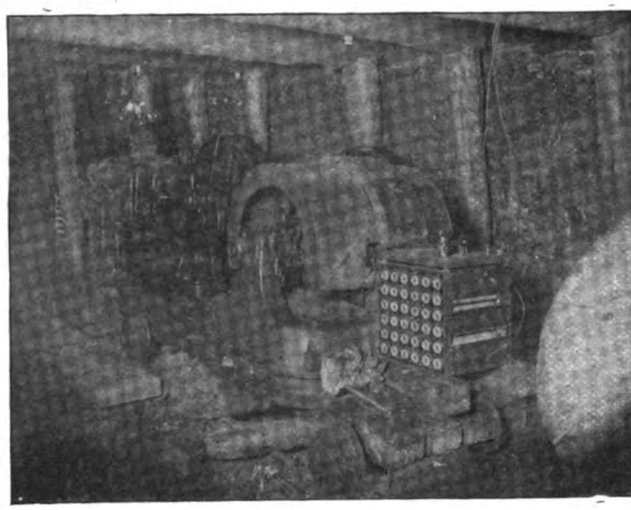
One generating unit only was installed, it being the intention of the Fuel Company to install the second reserve unit as soon as the electric system should demonstrate its success. The engine is a vertical cross compound marine type, and



ELECTRIC GENERATING PLANT, COLORADO FUEL AND IRON CO.

designed by E. F. Williams, of New York City. The cylinders are 11x19x15-inch stroke, developing 150 horse-power, at 250 revolutions, non-condensing. The condenser is a Wheeler surface condenser of the "Admiralty" type. The generator, mounted direct upon the shaft of the engine, has a capacity of 190 amperes and 550 volts. The generator, as well as all the motors, are multipolar machines, built by the General Electric Company. The switch board is of polished slate, and is equipped with the latest improved instruments and safety appliances. To insure absolute protection from lightning, which is very severe in this locality, all circuits are placed underground. The important circuits consist of iron armored and lead cables, while the lighting circuits are made by running rubber covered wire in iron pipe. The mine circuit consists of No. 0000 weather-proof wire, supported on triple petticoat glass insulators and iron-wood brackets, nailed to the mine props.

A 10 horse-power multipolar motor drives two shaking coal screens on the tipple, another 10 horse-power motor runs the



ELECTRIC MINE PUMP, COLORADO FUEL AND IRON CO.

machine shop, and a 25 horse-power motor drives the 20-foot ventilating fan. The installation of these motors displaces a similar number of engines and does away with about 1,000 feet of steam pipe, the condensation in which was no small loss.

There are two small pumps, used as sinking pumps, which are of the duplex type, having water ends, of the Deane Company make, and driven through gearing, by a 15 horse-power motor, mounted on the same frame. The cylinders are 7x 10-inch, and have a capacity of 250 gallons per minute, against a head of 115 feet. The pumps are mounted on a four-wheel truck, and can be moved around as desired. The station pumps, two in number, are double acting duplex, with water ends of Deane Company's make, and cylinders 9½x12-inch, geared to a 110 horse-power motor. These pumps have each a capacity of 600 gallons per minute, against a head of 400 feet.

Shortly after the order was given to erect the electric plant the No. 1 mine encountered an increased flow of water, which flooded the mine, the water coming up the slope a distance of 1,500 feet before it was held in check, and a pump was placed at this point to hold the water until the electric pumps could be put in operation. The water has since been pumped down about 700 feet by the electric pumps, and the work has been as severe a test on the pumps as any skeptic could desire. If the remainder of the pumping is completed with as good success as that already done, it may be truly said that the electric pump has come to stay. For over a month the two small electric and an air pump have been working side by side in an entry 10 feet wide by 5 feet high, with the exhaust of the air pump, into which a stream of water is discharged to prevent it from freezing, discharging so near the electric pump that it was necessary to protect the latter from the water by an oilcloth. This is certainly a good test for the waterproof properties of the motors, which are still doing their work and appear to be in excellent condition.

The average of numerous tests on the two small electric pumps gave the following results:

Average gallons per minute discharged	500
Average pressure at pumps	56.5 lbs.
Average strokes per minute, each pump	172
Average amperes	37
Average station voltage	475
Average indicated horse-power at engine	32.86
Average horse-power at pump discharge	16.4

Efficiency:	Per Cent.
Generator unit, engine and dynamo	71.5
Motor, pump and line	70
Total, from cylinder of engine to water discharge of pump	50

As soon as the first station pump was started and in good running order, tests were made, with the following results:

Average gallons per minute discharged	650
Average pressure at pump	64 lbs.
Average strokes per minute	188
Average amperes	53.5
Average station voltage	550
Average indicated horse-power at engine	53.6
Average horse-power at pump discharge	24

Efficiency:

	Per Cent.
Generating unit, engine and dynamo	73
Motor, pump and line	61
Total, from engine cylinder to pump discharge	44.5

Although the total efficiency with the small pumps is as high as predicted, it is nevertheless true that the engine and dynamo are working at a disadvantage with a load of but 20 per cent. of their rated capacity. In the case of the large pump, the generating unit is underloaded, as is also the pump, which combine to bring the total efficiency below the estimated 50 per cent. When the mine is finally pumped out and all the pumps and motors are running, the generator and engine will have a comfortable load, and it is safe to say that the total efficiency of the pumping plant will then be very close to 60 per cent.

The fact remains, however, that at the efficiency above shown by the present working, the former pumping of 400 gallons per minute against 120 pounds pressure, which equals 28 horse-power, can be accomplished by the electric plant with but 56 horse-power at the surface, instead of 312 as before!

As in the case of the compressed air plant, let us go back of the steam cylinders to the boilers. The engine running the generator was supplied with steam from the battery of boilers operating the compressors, but the piping is so arranged that one horizontal tubular boiler, 60 inches by 16 feet, could be cut off from the rest of the battery and supply steam to the electric plant alone. This was not the regular practice, because all the boilers were required to supply the necessary steam, even when two compressors were running; but on several occasions, when the main steam line was shut down for an hour or more, the electric plant was run on the one boiler, with ease, the safety valve popping more than once during the run, and this with the engine running non-condensing.

Qualitatively speaking, actual results with the compressed air and electric plants, which are the subject of this article, show that the work of pumping calling for 312 horse-power and 8 boilers in the case of compressed air, could be done by electricity with but 56 horse-power and one boiler, disregarding even the use of a compound engine and a condenser.

Further, the writer has no hesitancy in saying that the whole plant of pumps and machinery formerly requiring the eight boilers, taxed to their utmost, can be operated by the present electric plant with but the one horizontal tubular boiler.

MOTORS FOR ROLLING MILLS IN SWEDEN.

An interesting power transmission plant has recently been installed at the Bongbro Iron Works, Sweden. Water power is utilized, the generating plant comprising two 50 horse-power turbines, and three three-phase dynamos. The current is used to drive a plate-rolling mill and a billet mill, to each of which a large motor is connected.

PERSONAL.

MR. W. H. REYNOLDS is the electrician of the Newton Electric Light Company, Sussex County, N. J.

MR. E. S. WHITE, of the Construction Bureau in the City Works Department, has been placed in charge of the subway work in Brooklyn, and has Mr. H. S. Wynkoop, the electrical and gas expert, associated with him. The old commission, which cost the electrical companies $16,000 per year, is dead, but its duties devolve on the Mayor and City Works Commissioner.

MR. A. LANGSTAFF JOHNSTON, C. E., who has been in charge of the construction of the road on Broad street, Richmond, Va., was given a dinner on the occasion of his leaving the city for new work in Philadelphia. The affair took place at the Westmoreland Club, President John Skelton and other officers of the Richmond Traction Company being the hosts. Sixteen sat down to the table, and a most delightful evening was spent. Mr. Johnston was the recipient of many compliments.

TELEPHONY AND TELEGRAPHY.

CASUAL NOTES ON THE USE OF TELEPHONE ELECTION RETURNS.

BY GEORGE HELI GUY.

VARIOUS items have appeared in The Electrical Engineer as to the use of the telephone in delivering election returns, and as to the remarkable success achieved by that new departure. It is hardly yet realized, however, that the service was of a universal character, and that what was enjoyed in New York was but an example of the good work being done all over the country. Hereafter, people will not be satisfied unless at election time they can benefit by the instantaneity of the telephonic service in learning the news.

Many curious and amusing features were developed by the work. One was the fact that the telephone kept on beating the telegraph by an interval of from twenty minutes to half an hour. It was funny to see the district messengers dropping in silly from places served by the telegraph and copying off the bulletins received by telephone; it having been found out all over the city that delay in "relaying" the telephone messages from one circuit to another was simply a condition that did not confront the telephone management, however much it might mitigate against the telegraph.

The center of telephone operations was naturally the telephone building in Cortlandt street, which contains the principal operating room of the long distance company, as well as the main exchange of the local company. An entire floor of the building was given up to the work, and specially equipped for it. Starting from the center hall and extending on each wing were two rows of long-distance telephones, twenty-five in each row. To these were directly connected the long-distance lines from various parts of the country, and lines to police headquarters, the various newspaper offices, and committee headquarters. One set of telephones was used exclusively for receiving the news and the other for forwarding it on to different points. As each piece of news reached the receiving operator over his line, the bulletin was written out by him and taken by a messenger to the typewriting room, which was situated at the junction of the two lines of telephones. Here the message was copied out on the typewriter in manifold, and immediately distributed by another force of messengers to the outgoing telephones. It will be seen that a minute or less would suffice for this. A number of these outgoing instruments served only the local distributing system in New York City. In one room eight instruments served groups of four receiving telephones specially equipped at the various hotels and clubs in the city which had previously arranged for the service. Other telephones were connected to lines run to the different branch exchanges throughout New York, from which a redistribution of the bulletins was made to subscribers and to general enquirers over the telephone. One interesting feature of this series of instruments was a section devoted to lines running directly to the houses of some of the prominent candidates in the campaign, and to those of other eminent men particularly interested in the result of the election. One of these ran to the Long Island residence of a well known ex-Cabinet Minister, who was giving a large dinner party on Tuesday evening. He was thus able to entertain his guests throughout the evening with the earliest election news from all over the country. Even while the party was at dinner, the more important bulletins were read out from time to time.

In one room of the telephone building was a large staff of editors engaged in comparing the returns with those of the election of 1892. One of the most striking points of this extemporized service was its remarkable smoothness and efficiency. Everything worked with the steadiness and vim of a well tried and long systematized plan. Moreover, all this time the regular service of the exchange was going on without the slightest interference, three floors above. The staff engaged in the temporary work on the fifth floor numbered about 150. They were on duty from 5 o'clock in the evening, with relays, to 2 o'clock on Wednesday morning.

At the Thirty-eighth street exchange some fifty telephones, connected to the switchboard of the station in the same manner as the regular subscribers' lines, utilized the bulletins as fast as they came in over the direct line from Cortlandt street. When a subscriber from any part of the system called up for information regarding the returns, he was connected with one of these special instruments and his inquiry was attended to. The business here was very heavy, as the station is in the very center of the hotel and club district. About 1,500 calls were thus disposed of. At many of the up-town hotels, and

especially at the Windsor, large crowds waited eagerly for the publication of the telephone bulletins. At the Manhattan Club there were two lines of bulletin posters, one line containing the telegraphic dispatches strung on one side of the room, and another line opposite carrying the telephonic intelligence.

The grouping of a number of instruments together for attachment to one telephone at the exchange end gave rise to some amusing experiences. On one of the circuits was a piano factory. To while away the time between the bulletins, the proprietor swung two pianos into position, and entertained the rest of the people on the circuit with operatic selections and inspiring national airs. In another place, one of the participants in the service was a young lady, who from time to time discoursed music on the mandolin. The general tendency of those on the line was to become quite friendly and communicative, and frequently discussions of the situation were carried on and notes were compared on what was going on in the street immediately under the windows of the respective subscribers. Another point of great interest was brought out on one uptown circuit. As almost every man of the group happened to be well posted about some section of the country or had made a study of the bearing of many of the local returns, the telephonic bulletin was instantly supplemented by some special information for the general benefit. A comparison would be made with old election returns, or incidents in a recent visit to the section concerned would be described, so that the telephone returns were made vastly more suggestive than any telegram sent to an isolated individual could be. For instance, when the returns came early in the evening from Marion County, the interpretation of one of the parties on the line was that the State of Indiana would be carried for McKinley by fifteen to twenty thousand, at least, because a complete reversal of some fourteen thousand votes given for Cleveland in 1892 was indicated. In order to obviate the trouble of holding the receiver constantly to the ear, the regular telephone headgear was supplied to every one who wanted it. Sometimes, however, the listener would get tired and divest himself of his receiver for half an hour. When he readjusted it, as likely as not a member of his group, disguising his voice to resemble that of the "central," would interject some astounding information as to phenomenal and unheard of Democratic gains in a solid Republican State. In apartment houses particularly the telephonic delivery of the returns was much appreciated by the female residents, for the reason that they were no longer left behind by their husbands and brothers, and had no need to go out and expose themselves to the pushing and surging of wild crowds on the streets and squares. In one large house, a billboard, draped with two American flags, was put up on one side of the entrance hall. The pay station telephone alongside was equipped with an operator, and all the returns, as they came in—sometimes at the rate of two or three a minute—were quickly taken down on large blanks provided for the purpose, read out, and fixed upon the board. A great many of the ladies living in the house joined the listeners. The audience, which changed and grew during the evening, was delighted with this new form of politico-social function, and the impromptu telephone party was voted a tremendous success.

What was done in New York is typical of what was done throughout the country. One instance of the appreciation of the public will suffice. In Philadelphia, Dr. S. M. Plush sent out 5,000 postal cards to the subscribers asking them if they wished the service, which would cost them nothing. Fifteen hundred availed themselves of it, and they have not yet ceased sending in their thanks and congratulations.

WHICH EAR DO YOU LISTEN WITH?

A Berlin scientist has ascertained by experiment that a number of persons who use the telephone habitually hear better with the left ear than with the right. To educate the right ear to the same point he recommends holding the instrument in the right hand half the time. The common practice of the telephone companies is to place the receiver so that it will be applied to the left ear.

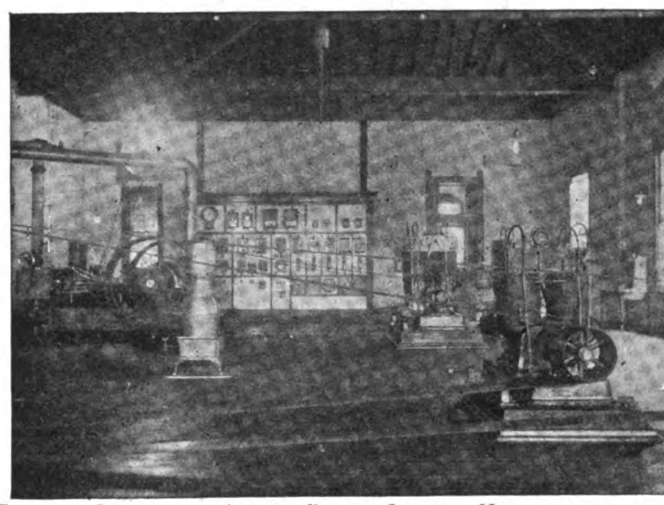
MIDNIGHT SPECULATION BY CABLE.

During election night, one firm of Wall street brokers arranged matters so that New Yorkers and others could anticipate the course of the local markets by speculating on the London exchange in advance. A private wire of the Western Union Telegraph Company furnished election returns and the office was in close communication with the London stock market by means of another private wire put in by the Anglo-American Cable Company. In this way the customers and friends of the firm were able to do early stock trading in the London market on the basis of the election returns, the firm having made arrangements for dealings on the London Stock Exchange with three of the largest London arbitrage brokers. The execution of orders on the London Stock Exchange begun about 4:30 o'clock Wednesday morning, or at 10 a. m. London time, when the Exchange on the other side of the Atlantic opens. The close of the London Exchange occurs shortly after 11 o'clock, New York time.

ELECTRIC HEATING.

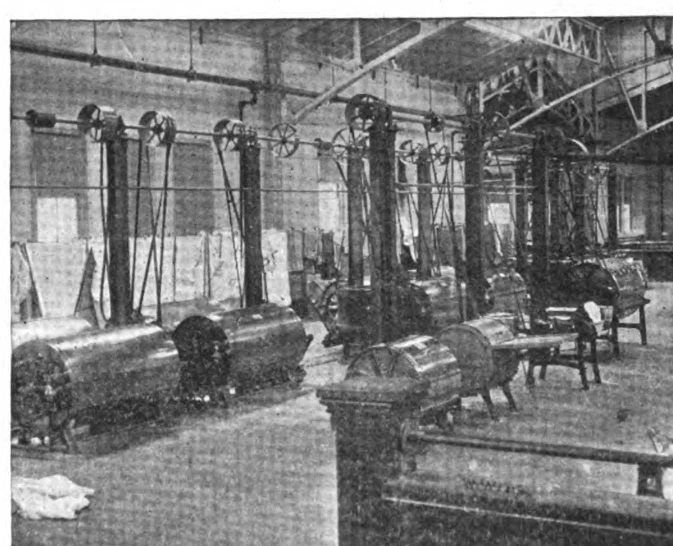
ELECTRIC LAUNDRY PLANT AT THE CENTRAL INDIANA HOSPITAL FOR THE INSANE.

EVERY day new applications of electricity develop and bring us nearer to the time when the most unpleasant and arduous occupations will become a pleasure to conduct. No new plan of electrical development is doing more to assist in bringing about this condition than that of electric heating. The electrical equipment of the Central Indiana Hospital for the Insane, at Indianapolis, Ind., is a striking example of one application where great economy of labor has been achieved



Electric Light and Power Plant, Indiana Hospital for the Insane.

and the conditions surrounding the operator vastly improved. The equipment of the laundry with electrically heated sad irons has reduced the number of employés at the ironing tables nearly one-half. The reasons why such results are

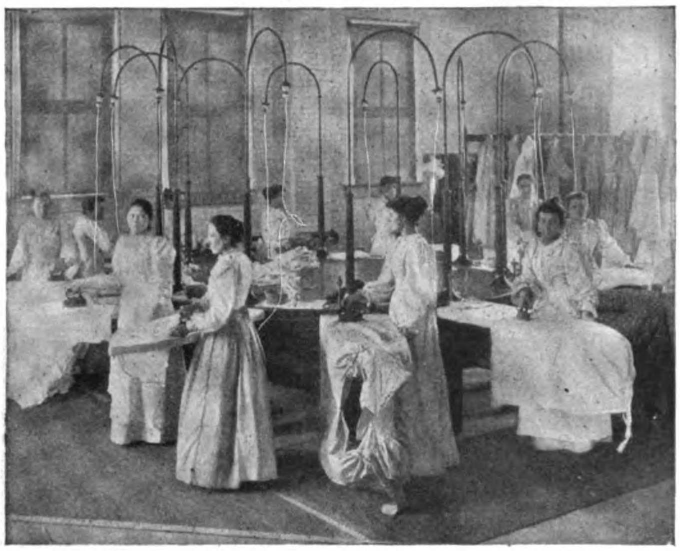


Laundry Machinery Driven by Electric Motor, Indiana Hospital for the Insane.

possible, are that the electric irons are constantly supplied with a uniform amount of heat, nearly all of which is absorbed by the work, and, by reason of the constant supply,

every rub is equally efficient; there being no appreciable heat radiated from the iron, it is apparent that in a room where the temperature can be regulated and there is no vitiation of the atmosphere due to combustion, much more work can be accomplished.

The complete electrical plant has been in full operation for about a year. It was planned and built with a view to embodying all features which would contribute to and produce an up-to-date and consequently most efficient combination.



ELECTRIC SAD IRON INSTALLATION IN INDIANA HOSPITAL FOR THE INSANE.

The equipment consists of three Phœnix boilers with a total capacity of 450 h. p. There are two 125 h. p. Phœnix center crank, high speed engines; each engine belted to two 45 k. w. Edison type, bi-polar compound, 110-volt generators. One 65 h. p. Phœnix engine is belted to one 25 k. w. generator of the same type, and one 20 arc light Edison generator. The illustration shows a partial view of the engine room. The three-wire system is used for all incandescent and power distribution, and all mains distributing to the different buildings for both arc and incandescent work are underground.

In addition to the usual switchboard equipment, all mains have separate amperemeters and voltmeter connections. The buildings are wired for 3,020-16 candle-power incandescent lamps. The twenty arc lights are used to light the campus, groves and drives; the grounds being very extensive, comprising several hundred acres.

One 3-h. p. motor is belted to an exhaust fan in the generator room. One 25 h. p. motor is belted to a counter shaft, driving the line shaft running twelve steam washing machines, two sterilizing machines, four centrifugal extractors, two starching machines and one tumbling machine, all made by the American Laundry Machine Company; and also driving one large Troy mangle, skirt ironers and one or two smaller machines. In the laundry there is placed a handsome switchboard, which is shown in the illustration, equipped with knife switches for controlling the supply of current to thirty-two laundry irons; also the automatic motor starter and the motor and main line switches. The equipment for electric sad irons is unique.

In the illustration is shown one of the tables arranged for twelve operators. All tables are of the same dimensions. The detailed description is of interest, bringing out as it does an arrangement, possible only with electric irons, which provides ample room for each operator, and yet permits the grouping of a large number in a comparatively small space. Each table is constructed of hard wood, the central portion being 10 feet in diameter and 3 feet high. From the periphery of the central section and 2 inches below the level of the same, branch out twelve ironing boards or tables, each 4 feet 6 inches long by 18 inches wide. Around the edge of the central section are placed twelve cast iron pedestals, about 2½ feet in height, from the top of which extends a section of ¾-inch iron pipe bent over, in the form as shown in the illustration. The wires are brought to the tables through conduits under the concrete floor and distributed beneath the tables to each upright, through which they pass to porcelain sockets at the ends of the bent pipes. In each socket is inserted a fusible plug attached to a flexible cord leading to the iron, depending in such position that it is always at the right and back of the operator. Small knife switches are conveniently placed near the base of the pedestal for the use of each operator. The clothing to be ironed is deposited on the center table, which is within easy reach of all.

The laundry is pleasantly situated in a special building, built for this purpose and is bright, and is clean and comfortable, the temperature at the ironing table being never more than 75 degrees F., except when the outside atmosphere is higher. The operators are neat and fresh looking, as would be expected from their surroundings.

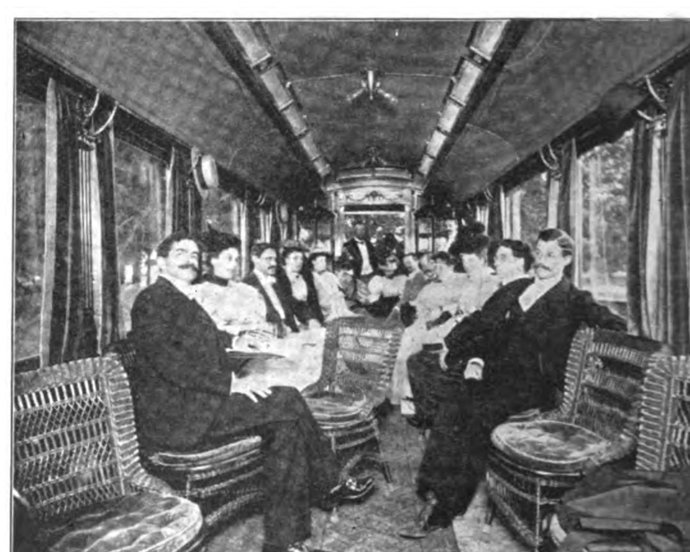
Only one-half of the number of employés are now used, that were required in the old laundry using irons heated with natural gas. This electric ironing installation was made by the American Electric Heating Corporation, of Boston, through their Chicago representative, Mr. F. P. Luther. It is only necessary to realize that one of these tables can easily be placed in a room 20 feet square and provide accommodations for each operator in every way far better, as to light, temperature, cleanliness and freedom of movement, than would be possible by any other means. The saving in cost of labor alone, natural gas being used for fuel in generating electricity, is more than sufficient to cover the total cost of the new method.

Dr. George F. Edenharter, superintendent of the institution, is a progressive physician, whose success in administering its affairs has been conspicuous and the Board of Control of the institution, consisting of J. S. Carson, John Ostaman and B. H. Davis, have always been ready to second his efforts. Much credit is due to E. E. Frost, chief engineer, for the well arranged and well ordered machinery plant, and for the electrical work, including the design of the table, the arrangement of the stands and many unique features, Joseph H. Stewart, the electrician, is responsible. He is enthusiastic and untiring in his efforts to extend the usefulness of the department which he controls and he is much appreciated by the officers of the institution.

ELECTRIC TRANSPORTATION.

THE "DRY GOODS TROLLEY" IN BROOKLYN.

THE Brooklyn Heights Railroad Company have recently established parlor car service between the village of Flushing and the city of Brooklyn. Flushing has a population of between nine and ten thousand and is something more than eleven miles distant from Brooklyn proper. The cars have been in service for a little more than three weeks, and already the patronage they have secured is abundant proof that the action of the railway company is appreciated by the ladies of Flushing. The service is particularly for shoppers, who wish to reach the large dry goods stores in Brooklyn.

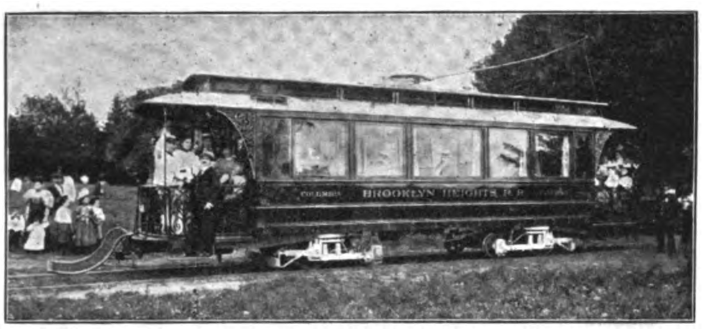


INTERIOR VIEW OF BROOKLYN DRY GOODS OR PARLOR CAR.

The cars run twice each week, on Tuesdays and Fridays, making two round trips on each of these two days, leaving Flushing at 9:30 in the morning and again at 2 o'clock in the afternoon, and returning from Brooklyn at 12:15 and 4:45 p.

m., in the first case reaching Flushing in time for a late lunch and in the second place returning the passengers in good time for dinner.

The Brooklyn treminus is at Flatbush avenue, which is about the uptown boundary of the important drygoods trade of the city. The regular parlor cars of the road are used. They are equipped with easy chairs, upholstered in green, and the trip includes the services of a porter. No stops are made between the two points, so that all the privacy and seclusion of a well-appointed parlor car is given the patrons of this up-to-date surface road. The usual fare from Flushing to Brooklyn for a round trip is twenty cents, but on the parlor cars an ad-



EXTERIOR VIEW OF BROOKLYN DRY GOODS CAR.

ditional fee of only 15 cents is charged, which counts but little as compared with the comfort of traveling. The arrangement prevents overcrowding, of course, and adds a degree of comfort and elegance to this method of traveling, which the ordinary trolley car does not seem to possess. The parlor cars of the Brooklyn Heights Railroad are a feature of the road in themselves. Three of them are now in service, two of them, the Columbia and Amphion, being built by the Barney & Smith Co., of Dayton, while the Montauk was built by J. G. Brill & Co., Philadelphia. The cars are 35½ feet in length over all and are fitted up in the highest type of modern street car manufacture. The illustrations herewith show respectively the interior and exterior of the car Columbia, from which a fair idea of their beauty may be gathered.

THE INSTITUTE DISCUSSION ON ELECTRIC TRACTION UNDER STEAM RAILWAY CONDITIONS.—II.

BY CHARLES K. STEARNS.

THE information obtained from the operation of the Nantasket electrical line, during the summer of 1895, was more or less of a general nature, as the chief object in view from the standpoint of the railroad officials was to demonstrate that an electrically equipped road could be operated as satisfactorily in regard to the facility of handling large numbers of passengers on time, as a steam road.

This point was proven beyond doubt, as the railroad officials have expressed themselves as satisfied after observing the ease with which the trains carried the large number of people the boat line brought to the trains at Pemberton, the extreme end of the line.

The cost of operating this line during its first season was roughly obtained, but the experimental nature of the car equipments was such as to render any figures as to the cost per train mile anything but accurate.

The equipment in the station is no doubt well known; suffice it to say, that there were installed two 500 k. w. direct connected generators wound for 600 volts potential; two compound condensing Green engines of about 1,000 h. p. capacity each, and eight return flue boilers, 18' x 72" diameter.

The train schedule of July, 1895, called for 150 trains per week day, or an average of 148.1 trains per day, including Sundays, and in 1896, 66 trains per day, or, including Sundays, an average of 68 trains per day. In 1895 these trains consisted of a sufficient number of cars to accommodate the people, but in 1896 the trains were limited to two cars, a motor car and trailer. To accommodate the passenger traffic, extra trains were made up and run between the regular scheduled trains. A fair average on Sundays would be about 150 trains, and week days 75 trains per day. This partially accounts for the difference in the coal consumption in 1895 and 1896, although in 1896 the engines were run condensing, while in 1895, non-condensing.

The line operated in 1895 was 6.86 miles of double track, equipped with special trolley wire, and in 1896 the same length of trolley line, with the addition of 3.64 miles of double track equipped with the third rail. The actual rail laid is about three miles double track, allowing for omissions of the rail at the crossings and stations. The distance from the power station to the end of the third rail is 4.75 miles, and to the end of the trolley line 5.75 miles.

The following table, although incomplete, gives some idea of the operation of the power station during July, 1895 and 1896:

	July, 1895.	July, 1896.
Hours run	605⅛	546¼
[1] Ave. elec. h. p. per nour...	245	349'/₁₀
Pounds coal burned	629,575	571,100
Coal per e. h. p. hour.......	4.24	68
Average trains per day	148.1	2.99
Average cars per train	2.1	2
Maximum cars per train	7	2
Train miles	32,803	44,173
Passengers	267,143	....
Tons passengers	18,700	....
Tons dead load	162,089	....
Tons total load.............	180,789	....
P. c. pay'g load to dead load.	10.2	....

In regard to the third rail equipment, it must be remembered that this was in the nature of an experiment, and several defects have been noted, which no doubt will be corrected in the future.

The rail itself is about 100 pounds section, rolled in the form of an angle of 110 degrees, with a standard rail top or surface for the shoe. This rail, as originally installed, was bonded wth cast copper bonds, and further supported by insulating blocks placed 7½ feet from each end. This was found insufficient, and fish plates were put in with a flexible copper bond and the rail supported by insulating blocks placed as near the ends as possible, with an additional block in the center to prevent vibration. These blocks are about 6 inches high, and fit the angle of the rail. This rail is not continuous, the grade crossings, of which there are several, being omitted, and the train running by momentum over them. This was necessary, as the width of some of these crossings is considerably greater than the length of the motor car. At the stations, also, the third rail is omitted and the overhead wire used. The installation consists, therefore, of a combination of third rail and overhead wire, the train starting out of the stations by the overhead wire and trolley, and running between stations by the third rail and shoe.

I cannot say that this plan is very satisfactory, particularly at night, when the different crossings are emphasized by darkness in the cars. The third rail, as now laid, is alive the entire length. It seems to me a question as to the advisability of operating a line with a 500-volt difference of potential in a position where there is liability of careless persons coming in contact with it. One accident has occurred and, although I understand legally, the public are not allowed on the right of way, the liability occurs of careless parties or workmen coming in contact with the two rails.

The regular steam rail used is 6 inches high. The third rail is 7 inches from the tie. This allows a clearance of 2½ inches from the pilot of a regular locomotive, provided this pilot is up to standard. There have been several cases where a locomotive pilot, chain or brake rod on a steam train running over the third rail section, has come in contact with the third rail and caused a short circuit of such length that it was found impossible to keep the current on this section of the electric branch. This section, I will state, is connected with the power station switchboard by a separate feeder and circuit breaker. In these cases the electric trains have come to a standstill until the steam train was off the section.

From these considerations it seems advisable to adopt a system where the conductor, if of the third rail type, is alive only at points where it is actually used, or at least divide the line into blocks, so that one train will be in a block at a time.

The insulation resistance of the pole line in 1895 was 140 ohms, or an average leakage of 4.7 amperes. This is on a line consisting of 577 Georgia pine poles, the trolley wire being fastened to angle iron cross-arms, which are bolted to the poles by two ¾-inch through bolts. No insulators are used. On the third rail there are about 3,500 points of support. I am sorry to say that I have been unable to obtain information as to the leakage on the third rail under varying weather conditions.

[1] During July, 1895, power was furnished by the station to operate the Hull Street Railway, the average of which was 30 h. p. by separate wattmeter. Consequently, the average power for the railroad was 215 h. p. 349 h. p. in 1896 includes about 40 h. p. furnished the Braintree & Weymouth Street Railway, so that the power for the railroad amounts to 309 h. p.

A serious objection to the present installation of the third rail is the connection by lead covered cables between the ends of the rails at crossings and stations. The surface leakage from the rail to the lead covering must be considerable, although I am not aware as to whether it has been measured or not. The outside covering of the cables has been found to be very sensibly alive.

Aside from the use of the third rail or trolley wire I believe that more uniformity of load in the station should be obtained by the use of storage batteries either on the cars or in the station. The extreme demands for power on the line, when seventy-five trains were in service, and these trains heavy, were very noticeable compared with the service of 150 trains per day in July, 1895.

In conclusion, it seems very desirable to put in a third rail in preference to the overhead trolley wire in such a manner as to avoid any liability of injury from accidental contact with the rail. In other words, put in the rail in blocks and then only such part as is in actual use to be active. A method of this kind would reduce the leakage to a minimum and place the electric road on an equal footing with the present block system of steam railroading.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Electro-Physics:

ON THE ACTION OF LIGHT ON THE SPARK DISCHARGE.—By E. Warburg. Author discusses the work of Herz, who showed that an electric arc kept about ¼ meter away from the secondaries of an induction coil, will help in producing a discharge in the secondary, even when the terminals are so far apart that under ordinary conditions such a spark can no longer be produced. Author has not only repeated these, but has also added a series of additional experimental data in the same line of work.—"Annal. de Phys. & Chim.," No. 9, '96.

TO THE DEMONSTRATION OF MUTUAL INFLUENCE OF TWO SPARK GAPS.—By Ignaz. Klemencic. An arrangement is illustrated and explained by means of which the mutual influence of two secondaries of two induction coil can be demonstrated without much manipulation.—"Annal. d. Phys. & Chim.," No. 9, '96.

EXPERIMENTAL RESEARCHES WITH GEISSLER TUBES.—By R. W. Wood. These researches include the determination of temperature in the Geissler tubes. Author explains his instruments and methods.—"Annal. d. Phys. & Chim.," No. 10, '96.

ELECTROSTATIC DEFLECTION OF CATHODE RAYS.—By G. Jaumann. That the electrostatic deflection exists is shown by several conclusive experiments. Thus an additional property of the cathode rays is established.—"Ann. d. Phys. u. Chemic.," No. 10, '96.

ELECTRIC CURRENTS THROUGH AIR AT DIFFERENT DENSITIES.—By Lord Kelvin, J. T. Bottomley and Magnus Maclean. Paper read before the British Assoc. An account of measurements of electric currents through air at different densities down to one five-millionth of the density of ordinary air. These experiments were made with the Wimshurst machine, and the general conclusion reached was as follows: If a curve be drawn for a constant difference in potential, with air densities as abscissæ and currents as ordinates, we find the curve rising as the air density is diminished to about 1-1,000 to 1-1,500 of the ordinary density, then falling again as the density is still further reduced to about a five-millionth of ordinary density. Lond. "Elec. Eng'r.," Oct. 9, '96.

Electro-Chemistry:

RESISTANCE OF ELECTROLYSIS.—By Max Wien. Dynamometer tests have shown that resistance of electrolytes under the influence of the alternating current increases; that is, it appears greater than what could be expected from the same dimensions and the same conductivity.—"Annal. de. Phys. & Chim.," No. 10, '96.

Railways:

LIVERPOOL OVERHEAD RAILWAY.—By S. B. Cottrell. Paper read before the Brit. Assoc. Besides the historical development of the enterprise, details of the electric installations are given, the essentials of which are as follows: Trains consist of two carriages, each 45 feet long, 8 feet 6 inches wide. Each car contains seating capacity for 16 first class and 41 second class passengers. The tractive force of each motor at rim of wheel, 2 feet 9 inches diameter, with 120 amperes, is about 1,790 pounds. A train fully loaded weighs 38 tons, of which motor equipment is about 6½ tons. Several tables accompany the article, which indicate the costs per mile, etc. Lond. "Elec. Eng'r.," Oct. 16, '96.

JUNGFRAU MOUNTAIN ELECTRIC RAILWAY, SWITZERLAND.—Details of one of the most remarkable electric railway enterprises yet proposed. "Elec. Eng'r.," Nov. 18, '96.

ELECTRIC TRACTION UNDER STEAM RAILWAY CONDITIONS.—Topical discussion before the Am. Inst. of Elec. Eng'rs. Discussion opened by Dr. Chas. E. Emery, whose remarks appear in "Elec. Eng'r.," Nov. 18, '96.

A MODEL ELECTRIC RAILWAY PLANT.—Some details of the Fair Haven and Westville road, with views of power house, branches of road and a diagram showing the dynamos and connections of the wires in the power house. "Scient. Am. Suppl.," Nov. 14, '96.

ELECTRIC RAILWAY IN FRANKFURT-ON-THE-MAIN.—An electric road is proposed, where the company which is to undertake the running must take the alternating current from the city and use rectifiers for generating the direct current. "Elektrotech. Zeitsch.,' Nov. 5, '96.

Lighting:

FREE SUPPLY OF INCANDESCENT LAMPS TO CONSUMERS.—By Alfred H. Gibbings. Author shows, first, the reasons why the supply of lamps should be in the hands of the corporation, apart from the question of free distribution; second, the disadvantages arising from the sale of lamps, and, third, the basis of supply, and the financial aspect of providing lamps without charge.—"Lightning," Oct. 22, '96.

PROPOSITION OF THE COMMITTEE ON INCANDESCENT LAMP STANDARDS.—The rules laid down are for 60-70 and 95-125-volt for 3-4 watts per candle, and for 10, 16, 25 and 32 candle-power lamps. "Elek. Zeitschr.," Nov. 5, '96.

Magnetism:

COMPARISON AND REDUCTION OF MAGNETIC OBSERVATIONS.—Report of the committee to the Brit. Assoc. The report deals in detail with the so-called "non-cyclic" effects during the years 1890-1895. Lond. "Elec. Eng'r.," Oct. 23, '96.

Measurements:

REPORT ON THE CALIBRATION OF THE SCIENTIFIC INSTRUMENTS OF THE LATE DR. JANLE.—By J. D. Charlton. The results obtained by the mechanical method of determining the heat equivalent differs from the electrical method. Author believes this error to be due to an error of determining the current strength.—"Proc. Roy. Soc.," 59, pp. 345-360; note in "Wiedemann's Beiblätter," Vol. 20, No. 9.

Miscellaneous:

ELECTRIC CARRIAGES.—The advantages of the new Jeantaud carrage are described. "L'Ind. Elec.," Oct. 25, '96.

Roentgen Rays:

WAVE LENGTH OF ROENTGEN RAYS.—By L. Fromm. Author, judging from experiments carried out by himself, thinks that the rays are about .000014 mm., or 15 times smaller than the shortest ultra-violet wave.—"Ann. d. Phys. u. Chem.," No. 10, '96.

Storage Batteries:

GULCHER ACCUMULATORS.—Special methods are employed to lighten the battery as much as possible. The capacity per kilogram of positive electrode is about 44 ampere hours. "Elektrot. Zeitschr.," Oct. 29, '96.

STANDARD CELLS.—By Henry S. Carhart. Referring to two papers which have recently appeared, one by Ayrton and Cooper, another by W. Hilbert, Prof. Carhart points out that these writers have brought out points, which are known for several years, and he gives his various sources as well as dates under which he himself has published these data. "Elec. World," Nov. 14, '96.

Wiring:

INSULATED WIRES AND CABLES.—By J. Draper Bishop. The first of a series of articles treating construction and design, insulation efficiency and defects.—"Elec. World.," Nov. 14, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED NOV. 10, 1896.

ELECTRIC BURGLAR ALARM. C. Coleman, Chicago, Ill., 570,906. Filed Dec. 21, 1895.
Embodies a meter electrically connected with the main circuit and adapted to complete the alarm circuit upon a variation in the condition of the main circuit.

ELECTRIC ANNUNCIATOR. J. Stamm, Stuttgart, Germany, 570,967. Filed July 10, 1895.
Composed of central station, push button, wire connections, a series of electromagnets, and electromagnetic circuit closers adapted to swing the electromagnets in groups into the circuit.

ELECTRICALLY CONTROLLED DERAILS FOR RAILWAY CROSSINGS. J. P. Coleman, Edgewood Park, Pa., 571,107. Filed June 1, 1896.
Means for locking the switches and signals of a single track railway grade crossing.

Batteries, Secondary:—

ELECTRIC STORAGE BATTERY. T. W. Allan, London, England, 571,059. Filed Feb. 19, 1896.
An accumulator plate comprising a rectangular frame having integral inwardly extending flanges, and a set of stays upon each face of the frame having beveled edges, perforations in three of its edges and in the flanges, and having one edge left open for the removal of the core in casting.

ELECTRODE FOR SECONDARY BATTERIES. H. Woodward, Toronto, Canada, 571,143. Filed March 23, 1896.
Comprises a perforated tube; a central ribbon of lead forming a core; a filling of pellets or red oxide of lead, and plates dividing the filling of pellets into a series of layers.

Conductors, Conduits and Insulators;—

ELECTRIC LIGHT ATTACHMENT. J. H. Rusby, Nutley, N. J., 571,248. Filed April 30, 1896.
Insulator attachment for suspending an electric lamp from a ceiling or wall.

ELECTRIC WALL BOX. W. F. Bossert, Utica, N. Y., 571,297. Filed Aug. 3, 1896.
Consists of a wall box having openings adapted to receive electric conduits, plug plates wedged in the openings and substantially coinciding with the exterior and interior surfaces of the walls of the box.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. J. F. Kelly and C. C. Chesney, Pittsfield, Mass., 571,270. Filed July 30, 1896.
A system of distribution in which the electromotive force of the current in the line can be varied so as to make up for line losses and the like without affecting a common magnetic field of the generator or the system as a whole.

SYSTEM OF ELECTRICAL DISTRIBUTION. C. C. Chesney and J. F. Kelly, Pittsfield, Mass., 571,300. Filed Dec. 3, 1895.
Similar to above.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE G. E. Dorman, Chicago, Ill., 570,914. Filed Feb. 4, 1896.
An armature comprising a wheel having a rim and a central hub and being provided with slots which extend from the edges to the spokes, a series of projecting arms of laminated iron fastened to the rim and separated by spaces which register with the slots in the rim, said projecting arms each composed of a series of insulated plates of iron.

ELECTRIC MOTOR. G. R. Green, Philadelphia, Pa., 571,043. Filed March 7, 1896.
Oscillating motor.

FIELD MAGNET POLE. J. J. Wood, Fort Wayne, Ind., 571,181. Filed Sept. 8, 1896.
A laminated field pole adapted at one end to be embedded in a cast yoke made of laminæ having sides of unequal length at their embedded ends, and reversed at intervals to form oblique ribs projecting to alternately opposite sides.

MAGNETO-GENERATOR. J. C. Francis, New York, 571,305. Filed Jan. 2, 1896.
The combination of an electromagnetic generator, of the contacts, the contact lever, and a slack chain arranged to operate the lever when the chain is tightened.

DYNAMO ELECTRIC MACHINE. R. Lundell, Brooklyn, N. Y., 571,310. Filed Oct. 7, 1895.
The field magnet cores and pole pieces are so divided and arranged that the magnetic reluctance is caused to increase in the direction of rotation of the armature.

Electro-Metallurgy:

ELECTROLYSIS OF IRON. A. S. Ramage, Cleveland, O., 571,956. Filed Nov. 4, 1895.
A compound for use in electrolyzing iron composed of sulfate of iron, sulfate of soda, sulfate of ammonia, in suitable proportions, with water to form a solution substantially 20 per cent. strong.

Lamps and Appurtenances:—

ELECTRIC LAMP. R. M. Hunter, Philadelphia, Pa., 571,123. Filed Oct. 5, 1893.
A focussing arc lamp.

ELECTRIC ARC LAMP. H. R. Palmer, Norfolk, Va., 571,137. Filed March 25, 1896.
Employs an adjustable stop or cut-out, whereby the descent of the upper carbon will be arrested, and the light may be extinguished at a determined line.

Measurement:—

ELECTRIC METER. C. Wirt., G. R. Green and H. Burger, Philadelphia, Pa., 571,032. Filed March 7, 1896.
A solenoid instrument.

ELECTRIC METER. H. Burger and W. H. McFall, Philadelphia, Pa., 571,036. Filed March 7, 1896.
An oscillating cam driven by a motor, the working surface of the cam being constructed so as to move the register actuating device in the other direction with a gradually decreasing speed of movement.

ELECTRIC METER. H. Burger and W. H. McFall, Philadelphia, Pa., 571,037. Filed March 7, 1896.
Details of the above.

Miscellaneous:—

ELECTRICAL SELF-PLAYING PIANO. G. H. Davis, New York, 570,911. Filed Sept. 14, 1895.
Relates to music sheet holder.

DETENT FOR RATCHET WHEELS. W. D. Marks, Philadelphia, Pa., 571,050. Filed Aug. 22, 1896.
Consists of a ratchet wheel, a spring detent therefor and an adjustable weight for regulating the pressure of the detent.

COMPOSITION OF MATTER FOR MANUFACTURING CALCIUM CARBID. H. Eldridge, D. J. Clark and M. W. Wambaugh, Galveston, Tex., 571,084. Filed April 30, 1896.
Composed of quicklime, carbon, soda and borax.

ELECTRICAL DISCHARGE DEVICE. C. E. Skinner, Pittsburg, Pa., 571,099. Filed May 21, 1896.
Electrodes for spark discharge.

BLACKLEADING MACHINE. W. H. Nichols, Boston, and R. Stephenson, Quincy, Mass., 571,199. Filed Jan. 27, 1896.
Relates to machines for applying powdered plumbago to wax molds prior to the electrotyping process.

ELECTRIC HEATING APPARATUS. A. E. Appleyard, Natick, Mass., 571,257. Filed Jan. 30, 1896.
Comprises an electrical resistance contained in a space or chamber between an outer and inner tube located within a water receptacle.

ELECTRIC GAS LIGHTING DEVICE. E. Schmidt, Berlin, Germany, 571,288. Filed Aug. 1, 1896.
Consists of an electromagnet having an armature consisting of two independently movable members, a gas cock operatively connected to one member and an igniting device operatively connected to the other member.

Railways and Appliances:—

ELECTRIC LOCOMOTIVE. J. F. McLaughlin, Philadelphia, Pa., 570,945. Filed June 24, 1891.
An electric motor composed of two part armature and field magnet, the latter completely inclosing the former; and a two part friction clutch for connecting the armature with the car axle.

TROLLEY FOR ELECTRIC RAILWAYS. P. C. Macevoy, Brooklyn, N. Y., 571,092. Filed Dec. 10, 1895.
Embodies spring operated guide arms connected with the frame, adapted to be thrown upwardly when the pressure on the trolley wheel by the conductor wire is removed.

ELECTRIC RAILWAY TROLLEY. H. D. Hinckley, Hartford, Conn., 571,120. Filed Aug. 12, 1895.
Means whereby the trolley pole will be normally maintained in a working position, and whereby a retractive movement of the trolley pole will be automatically effective when the pole is thrown out of its working position.

STATION INDICATOR. D. E. Connor, Covington, Ky., 571,301. Filed June 29, 1896.
Details of construction.

Switches, Cut-Outs, Etc:—

AUTOMATIC SAFETY CLOSER. W. L. Pratt and F. E. Ripley, Adams, N. Y., 570,955. Filed Jan. 20, 1896.
Comprises a hinged arm carrying the loop connections, the arm being held normally in circuit by a fuse wire, an electromagnet and an armature for fusing the wire when the circuit upon the loop is broken.

MULTIPLE FUSE BLOCK. E. H. Montgomery, St. Paul, Minn., 571,093. Filed Aug. 10, 1895.
A switch adapted to be placed in each local circuit, so as to dispense with the necessity of other fuse blocks in the system.

AUTOMATIC CIRCUIT BREAKER. W. H. Powell, Hartford, Conn., 571,097. Filed June 15, 1896.
Details of construction.

LIGHTNING ARRESTER. A. J. Wurts, Pittsburg, Pa., 571,103. Filed March 11, 1896.
Comprises a non-conducting body and a pair of separated terminals provided with arc-suppressing means, and located in close proximity to one surface of the body, and means of repelling the air from the surface.

LIGHTNING ARRESTER. L. P. Culgan, Swissvale, Pa., 571,100. Filed June 1, 1896.
Comprises two tongues movable toward and from each other and provided with carbon buttons, the tongues being insulated from each other, and adapted to be connected to ground, and to a line wire, respectively.

ELECTRIC SWITCH. W. W. Hibbard, Rochester, N. Y., 571,119. Filed Nov. 21, 1893.
An arrangement by which signals sent over any number of separate main circuits may be transmitted to a side circuit without one interfering with another.

Telephones:—

TELEPHONE SWITCH. E. M. Harrison, Chicago, Ill., 571,162. Filed Nov. 21, 1894.
A telephone switch which may be operated by hand in connection with a suitable hook for supporting the receiving instrument.

MAGNETO TELEPHONE. E. M. and W. S. Harrison, Chicago, Ill., 571,190. Filed Nov. 21, 1894.
Comprises a diaphragm of permanent steel magnets, of unequal length, their like poles being separated at their lower ends by a diamagnetic heel-piece and electromagnetic coils on the pole pieces at the opposite ends.

OBITUARY.

FRANK P. ARBUCKLE.

Mr. F. P. Arbuckle, who was found dead under very suspicious circumstances, in a vacant lot at the uptown end of the Ninth avenue railroad, this city, on Nov. 19, was a well-known Westerner, and chairman of the Colorado Democratic States Committee. He was born in 1852; in 1870 he became connected with the telegraph service of the Kansas Pacific Railroad, building the line to Denver. He afterwards organized and carried on the Denver American District Telegraph Company, and one of his latest enterprises was the Denver-Highlands Electric Railway.

JAMES E. DEAN, the only son of Matthew Dean, president of the Municipal Electric Light Company, of Brooklyn, died on

November 1 in Guatemala, Central America. Mr. Dean was born in Brooklyn thirty-two years ago, and, after being graduated from Mount Pleasant Military Academy, went West. Four years ago he went to Guatemala. There he entered the electrical contracting business, and made money rapidly. It had been his intention to return home soon for a visit, but he was stricken with fever and succumbed in a few days. He was buried in Guatemala.

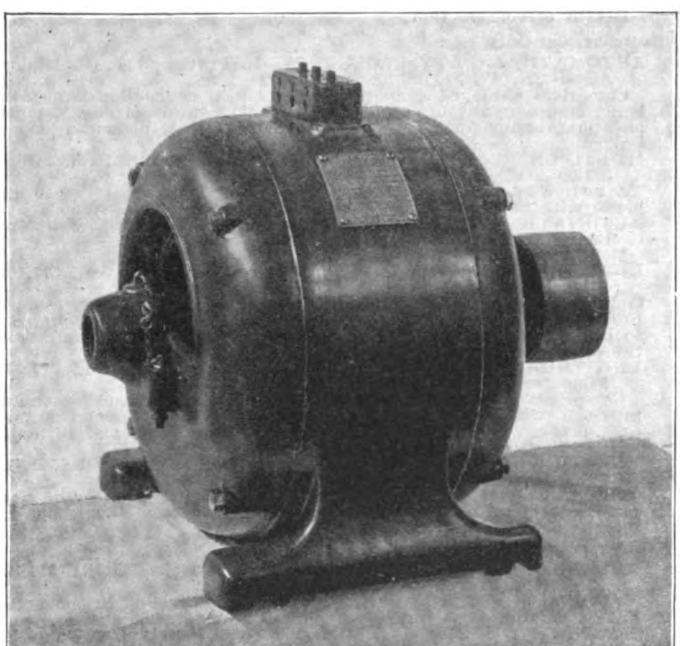
MR. WILLIAM G. ELLIS, president of the Amesbury National Bank, and a leader in the carriage building industry, died at Amesbury, Mass., on November 3, aged sixty-four. He was for several years the head of the Ellis Car Company.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

NEW G. E. HIGH FREQUENCY SINGLE PHASE AND THREE-PHASE INDCUTION MOTORS.

THE new single-phase and three-phase high frequency induction motors of the General Electric Company have been designed to operate from circuits of 125 cycles, and to run at any frequency within 10 per cent. greater or less than 125 cycles with corresponding increase or decrease in the speed. The liability of the high frequency synchronous motor to be thrown out of step with any fluctuation in the speed of the generator is a disadvantage which does not seem likely to be overcome. If the feeder supplying current to a motor is changed over to another generator—a frequent occurrence in central stations—a fluctuation occurs in the frequency, the high frequency synchronous motor is thrown out of step and is brought to a stop. This can only be prevented by running the high frequency generators in parallel or by using high fre-



G. E. HIGH FREQUENCY INDUCTION MOTOR.

quency induction motors and consideration of this fact has brought the new line of motors into existence.

Two lines of motors have been designed—those for three-phase circuits and those for single phase. The mechanical structure and electrical features of the standard G. E. 60-cycle induction motors, also distinguish these. The armature or induced element in all sizes larger than 5 horse-power has a polar winding and a revolving starting resistance cut out by means of a lever. In the 5 horse-power size and less, the armature either has the polar winding and starting resistance or is built with individually short-circuited coils. While the latter is cheaper, the starting current required is greater and the starting torque less, the efficiency also falling below that of the motor with the variable resistance.

The field is wound with the conductors in slots, the winding being supported by end shields, which protect them from outside mechanical injury. The self-oiling and self-adjusting bearing are amply large; the oil cannot overflow and no oil can run out at the armature end. The connection board on the motor has no bare terminal connections and no part of the active conductors are exposed.

The full load rating is not the heating limit, but is determined by the safe margin allowed for the overload carrying capacity. The rise in temperature above the surrounding atmosphere when run continuously for 10 hours at the rated full load is not over 45 degrees Centigrade.

The speed, practically constant, does not vary with changes of voltage and cannot exceed the rated speed. If speed variation is required on the three-phase motors it can be obtained by the addition of collector rings and brushes and a rheostat in the armature circuit. No speed variation is readily obtainable in the single-phase induction motor.

The starting torque and starting current of the three-phase high frequency motors with resistance in armature are from 25 to 30 per cent. in excess of the torque and current at rated load. For special cases the motor can be built for a much greater starting torque.

The single-phase motor requires a starting box, starting it with half load torque and about one and a half full load current in the case of the motor with variable armature resistance. The box consists of a non-inductive resistance and a choking coil, the object being to establish a displaced phase of e. m. f. and produce a starting torque. When the motor is up to speed, the box is cut out, and the motor then runs as a simple single-phase motor. This motor can also be started with full load torque and a little over twice load current, but this necessitates a larger box. The single-phase motor with independently short circuited coils or fixed resistance in the armature requires about twice this amount of current when starting and gives somewhat less torque.

These induction motors are totally without moving contacts, and are standard for 104 volts. The smaller sizes can be run upside down or sidewise fastened against the wall, greatly economizing floor space. The high frequency three-phase motors have been designed to meet a demand for power service principally from high frequency monocyclic generators, and may be wound two phase for use on two-phase circuits of similar frequency. The single-phase motor meets the demand created for a motor to be operated on the existing high frequency circuits.

SOME INTERESTING EXPERIMENTS IN LUBRICATION.

At the sixth annual or 32d meeting of the American Society of Mechanical Engineers, held at the rooms of the society in New York City, in December, 1895, Mr. Albert Kingsbury, Durham, N. H., read a paper on "Experiments on the Friction of Screws." The tests were made by the aid of a specially designed machine built at the New Hampshire College shops. It now forms a part of the laboratory equipment of the college.

The author did not consider that the tests showed that any one of the metals developed less friction than any of the others, but the tests are specially interesting because of the great lessening of friction by means of graphite, as will be shown by the following:

Lubricator.	Minimum.	Maximum.	Mean.
Lard Oil	.09	.25	.11
Heavy Machinery, Oil, (Mineral)	.11	.19	.143
Heavy Machinery, Oil and Graphite (Equal Volumes)	.03	.15	.07

Mr. Kingsbury was complimented by Professor Thurston for the work he had accomplished. Personally Prof. Thurston had found that Sperm oil was better than Lard oil for reducing friction in such instances. He trusted that Mr. Kingsbury would continue his investigations.

Mr. Kingsbury felt gratified at the manner in which his paper had been discussed, and in reply to a question that had been asked, he said that the Graphite used was from the Joseph Dixon Crucible Company, Jersey City, N. J. He said he did not intend anything in the way of an advertisement. He also added that he had tried to purify the graphite, but there was no gain. In order to satisfactorily employ the graphite the fit must be loose.

Some years ago, when Prof. Thurston was connected with the Stevens Institute, he made a series of experiments to determine with scientific accuracy the value of Graphite as a lubricant. He found that under the same number of pounds pressure, and traveling at the same rate of speed, the bearings lubricated with Dixon's Graphite, mixed with enough water to distribute it over the bearings, did nearly three times more work than the best quality of winter sperm oil. He also found that when 15 per cent., by weight, of graphite was added to the best quality of lubricating grease, he was able to run the bearings nearly six times longer, at the same high rate of speed, than when the bearings were lubricated with the same

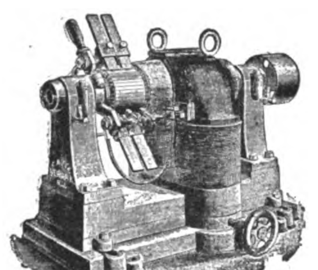
grease, without the addition of graphite. Furthermore, where the graphite was used there was no cutting and the bearings were in perfect condition.

Little, if any, of the commercial graphite in the market is fit for lubricating purposes, and bearings have been so frequently cut or ruined by its use, that there has been a very strong prejudice against its adoption by master mechanics and superintendents having charge of expensive machinery. It is safe to say, however, that when graphite is properly prepared, it will not only reduce friction much better than any oil or grease alone, but furthermore will perceptibly reduce the cost of lubrication.

THE ECK DYNAMOS AND MOTORS.

OUR illustration represents the type of new direct-current dynamos and motors now being brought out by Mr. C. A. Eck, 157-161 Oraton street, Newark, N. J., which combine the most essential features known to be best for the generation and use of electric currents. They embody the following valuable points: Perfect electrical proportioning, high efficiency, best insulation, simplicity of mechanical design, and best workmanship and materials. They are built with great care and no expense is spared either in materials or labor to make them as perfect as possible.

The field magnets are composed of wrought iron of the highest magnetic quality. The armature core is of the drum Pacinotti or iron clad type, proportioned with a view to maximum efficiency and slow speed; it is built up of well-insulated laminated iron, perfectly balanced to insure noiseless operation; the grooves are heavily lined with mica, the wire being completely embedded beneath the surface and covered with a plugging strip of mica, or fiber and securely bound by bands; consequently they will stand considerable rough usage. The commutator is of tempered copper, generous in size with many



THE ECK DIRECT CURRENT DYNAMO.

segments perfectly insulated under pressure with best mica and rigidly put together.

The bearings are all self-oiling and do not require attention oftener than once in two to four weeks. The bushing in which the shaft runs is of phosphor bronze and rests in universal or ball joints, to secure perfect alignment.

The brushes for the dynamos and motors of 110 volts and over are of coppered graphite or carbon; below 110 volts gauze or copper brushes are used. No, or very little current will pass through the spring of the brush holder and heat it because a better path is provided.

Each machine is thoroughly tested above its rated capacity before leaving the factory, and shipped in perfect order. If necessary, they will stand heavy overloads for short periods; change of load does not require shifting of brushes within its rated capacity, as the dynamos are all compound wound and are perfectly automatic in regulation.

SUNBEAM INCANDESCENT LAMP.

The following announcement has been issued by the Sunbeam Incandescent Lamp Co.:

We take pleasure in announcing that we have made arrangements to distribute the entire output of Sunbeam Lamps through the Western Electric Company, Chicago. In consequence of this arrangement, our Chicago office has been removed to the Western Electric Building.

All communications (excepting those relating to remittances) should be addressed to the Sunbeam Incandescent Lamp Co., 242 S. Jefferson St., Chicago. All lamps will be billed by the Western Electric Co., and remittances should be made to them.

We are also able to announce at this time that we have completed the equipment of our new factory at Desplaines, Ill. (just outside of Chicago limits) and we have not only very greatly increased our facilities, but have added in every department the most modern machinery and apparatus used in lamp manufacturing. We have also improved several processes of manufacture which will assist us in producing lamps more uniform and of a superior quality.

Those who are unacquainted with the Sunbeam Lamp as it is now made will find it to their advantage to place a trial order.

ANOTHER OF PENNOCK'S SCHEMES.

The subjoined unique circular will interest many people:

"THE PENNOCK ELECTRIC INVENTIONS.

"Electric Light. Electric Heat. Electric Power. Electric Ships. One hundred horse-power enters the Pennock voltage distributors, and one hundred thousand comes out. All produced at the cost of one hundred horse-power. All other inventors and magicians—Keeley, Tesla, Edison, Herrman, Kellar, et al.—knocked out. The Pennock inventions can duplicate with 200 horse-power the total horse-power that can be produced from Niagara Falls. A revolution indeed! 99,000 for 1. A fortune awaits your investment. Your money will grow in a night. We are selling the stock at $— per share. It may jump to higher figures at any time. The stock is full paid and unassessable. Address GEO. B. PENNOCK,
"193 Greenwich street, New York."

INPROVING TELEPHONE FACILITIES IN NEW YORK.

The New York Telephone Company has issued the following data, which contains several points of interest: The great improvement in the telephone service brought about by the complete reconstruction of the New York City plant on the metallic circuit basis, and the widening of the facilities by the extension of the system, and by large addition of subscribers, have led many of our subscribers to steadily increase their use of the service without providing additional facilities to cope with the increased traffic which their lines are called upon to carry. This leads to inconvenience, which is felt in many directions. The principal trouble is that an overburdened line is of necessity frequently reported "busy" to other subscribers calling for connection with it. This is a source of positive loss to the busy subscriber, as many calls intended for him are delayed, and some, no doubt, dropped altogether or directed elsewhere after one or two efforts to obtain connection have encountered a line almost constantly occupied with outgoing business.

The simplest form of relief for an overtaxed line is a double-track connection with the central office—two separate lines and stations, using one for outward and one for inward calls.

The charge for a second or auxiliary message rate station is $60 a year, all messages sent from it to be charged to the original station. If the original station is flat rate, the second line may be at the minimum message rate, viz., $90 a year for 600 local messages.

Where the telephonic requirements are on such a scale as to exceed the capacity of a double track arrangement with two stations, our sub-exchange system will be found admirably adapted to cope with the business, whatever its volume. This consists in placing telephone stations in different offices of an establishment as may be required. These telephones are all connected to a small switchboard from which trunk lines, in sufficient number to efficiently carry the traffic, run to the nearest central office. The system may be arranged for intercommunication between the sub-exchange stations if desired. Several large business firms in New York are now supplied with telephone service in this manner, and find the increased elacticity and capacity of the service a positive boon.

The rates for the sub-exchange system are: 4,000 messages, line and station complete, $225 a year; each additional station, $24 a year; each additional line to central office, $36 a year; additional messages, per 500, $15 a year.

THE BRUSH WORKS TO GO TO LYNN.

For some time past there have been persistent rumors with regard to the removal of the Brush Electric Company's plant to Lynn. Last week the reports were renewed. A special dispatch of Nov. 12 from Lynn, says: "Manager Walter C. Fish, of the Lynn works of the General Electric Company, says that it is true that the business of the Brush Electric Company, of Cleveland, O., is being moved to Lynn, and that hereafter the business of the Brush Company would be done in Lynn. The Brush Company is controlled by the General Electric Company, and manufacture arc-light dynamos and arc lamps. No additional buildings will have to be erected in Lynn, as the General Electric Company have plenty of factory space here in the buildings of the Thomson-Houston Electric Company.

INTERIOR CONDUIT IN THE WEST.

The trade will be interested to know that the Western Electric Company, of Chicago, has been given the agency for the products of the Interior Conduit and Insulation Company, of New York. All brass armored and iron armored conduits, elbows, couplings, fittings, etc., will be carried in stock in Chicago, and unusual facilities will be given to all jobbers and contractors for obtaining this material at the lowest prices.

The Interior Conduit Company has just brought out a special conduit which is much superior to anything which they have ever before placed upon the market. They have not only increased the excellence of this material, but have very materially decreased the price. The Western Electric Company is prepared to furnish new prices upon application. Coupled with this agency the Western Electric Company has also secured the agency for a fine line of standard, iron armored, slate-lined, panel, distributing, fuse, main and feeder terminals; also branch junction boxes. These boxes are specially designed and each box can be used on either two or three-wire system. Those interested should write for catalogues and special quotations.

CLAYTON AIR COMPRESSORS IN DEMAND.

A contract for twenty-five air compressors and twenty-five air receivers, of medium and small sizes, has been closed by the Clayton Air Compressor Works, Havemeyer Building, New York, with one company, delivery of the entire order to be made within six months. They also report sales of five air compressors of standard pattern during the first week in November, and the indications point to a decided revival of trade in air compressors, many orders having been held in abeyance pending the result of the election.

CONDUITS AND CABLES.

Mr. John T. McRoy, of Chicago, has brought out a little catalogue of his terra cotta conduit. The fact that the little booklet is terra cotta color adds to the suggestiveness of it. The catalogue deals with the character of the material used in the manufacture of the conduit and its practicability, and contains a little argument running through the pages as to the special value of the McRoy production, closing with some testimonial letters and an illustration of the strength of the conduit.

ADVERTISERS' HINTS.

THE ELECTRIC APPLIANCE COMPANY publish a letter testifying to the excellence of the Boudreaux dynamo brush.

C. A. ECK, 157 Oraton street, Newark, N. J., builds high grade dynamos and motors ranging from 1/8 to 10 horse-power in size.

THE F. J. PEARSON MANUFACTURING COMPANY, of St. Louis, are manufacturing a Crookes tube which they claim is superior to those of foreign make. The price is $5 net, delivered.

THE GLOBE ELECTRIC HEATING COMPANY, Philadelphia, Pa., illustrate in their "ad.," this issue, a portable heater designed for residences and offices. It consumes 6.8 amperes on 110-volt circuit, or 1.5 amperes on 500-volt circuit.

WILLIAM TOD & CO., Youngstown, Ohio, are building the Williams improved vertical engines. They are equipped with valves and gear capable of any rotative speed at which the shafts and reciprocating parts may be operated with safety, thus securing any speed desired.

MR. WM. TAYLOR, 203 Broadway, New York, is offering Edison incandescent lamps at 12 cents. There are about 7,000 of them, 16 candle power, ranging from 100 to 105 volts; are new and are sold at this figure as the voltage is too low for the circuits they were intended for.

WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., report their engine sales for October to have averaged 150 horse-power daily. This is all the more remarkable owing to the inclination of buyers to postpone purchasing until after the election, and the above company should be congratulated on having an engine that is considered a safe investment at all times.

J. B. COLT & CO., 115 Nassau street, New York, call attention to the Criterion magic lanterns used in giving the election returns in Printing House Square on the night of November 3. Each lantern was provided with one of their automatic arc focusing lamps, capable of the finest adjustment, as are all lanterns sold by this company, who manufacture them for stage and balcony uses, as well as for scientific work in colleges, laboratories, etc.

NEW YORK NOTES.

THE ELECTRIC RAILWAY COMPANY of the United States, owning the Field and Edison electric railway patents, at the meeting of its directors last week, decided to apply for a receiver to wind up the affairs of the company.

BROOKLYN NAVAL HOSPITAL. The firm of J. A. Walker & Company, Philadelphia, is carrying out work on two or three new buildings at the hospital. Electricity is to do the lighting, and two electric elevators will be furnished, each to be large enough to carry a patient on a cot with an attendant.

BAECHTOLD & PARKER ELECTRIC COMPANY, 79 Washington street, Brooklyn, have had to enlarge their floor space owing to an increased business. They are running with a full complement of men. Aside from electric repair work, they are offering a large and varied line of second-hand arc dynamos and lamps; also a line of incandescent dynamos.

RANDOLPH & SULLINGER, 114 Nassau st., New York, electrical engineers and contractors, designed and installed the electrical display, election night, at the Union League Club, consisting of red, white and blue streamers, legend of McKinley and Hobart, and seven large searchlights of their own design. Among the many buildings installed by this firm can be mentioned the Hotel Renaissance (all the wiring), show windows at Cammeyer's Shoe Store, motors and all the wiring in O'Neill's dry goods establishment.

THE ELECTRIC ENGINEERING AND SUPPLY COMPANY, of Syracuse, N. Y., have almost ready for distribution a very complete catalogue of about 125 pages, containing illustrations and price lists of all the articles of their manufacture, consisting of railway material, line material, hoods; a complete line of incandescent supplies, and a very extensive display and price lists of jack-knife switches. There will be over 25 pages of tabulated lists on their jack-knife switches. A special feature of this catalogue will be illustrations and prices of all switch parts and switchboard parts, all of which are illustrated and listed. The catalogue is No. 7.

MR. WM. S. TURNER has opened an office in the Postal-Telegraph Building, 253 Broadway, New York, where he will carry on a consulting and constructing engineering business in electric railways, lighting, power transmission and steam engineering, similar to that heretofore conducted by Woodbridge & Turner Engineering Company, which concern has recently discontinued business.

An active and continuous experience of ten years in designing, constructing, supervising and consulting in the abovementioned departments of engineering work enables Mr. Turner to merit confidence and good will and he proposes to maintain the highest standard of skill and workmanship in all departments of work entrusted to him.

WESTERN NOTES.

MR. F. B. DOWNING, assistant manager of the Keystone Electric Company, Erie, Pa., was a recent visitor to Chicago and the West in the interests of his company, and he feels very confident that they will have a considerable addition to their business in the near future.

MR. ALEX. CHURCHWARD, electrical engineer of the Excelsior Electric Company, made a recent trip to the West, and when in Chicago called in at the office of the Engineer. Mr. Churchward is most energetic, and it is reported that he is on the qui vive as to the expected installation of a large transmission plant in the West.

MR. C. E. WOODS, who is well known in the electrical trade, from the fact of his having been connected with the National Electric Company, Eau Claire, Wis., and the Standard Electric Company, Chicago, as a designer of dynamo electric machinery, and later by his work in inventing and developing the electric vehicles manufactured by the American Electric Vehicle Company, Chicago, has severed his connection with the latter company, and is now permanently connected with the Northern Electrical Manufacturing Company, Madison, Wis. Mr. Woods' duties in his new position will consist in designing motors and generators to be manufactured by this enterprising young concern, who are now more than ever in a position to push for business.

NEW ENGLAND NOTES.

THE AMERICAN ELECTRIC HEATING CORPORATION, Sears Building, Boston, has just issued to its friends a copy of King's Views of the Hub, a very pretty and interesting collection of halftones from photographs which give an excellent idea of modern Boston.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. DECEMBER 2, 1896. No. 448.

ELECTRIC LIGHTING.

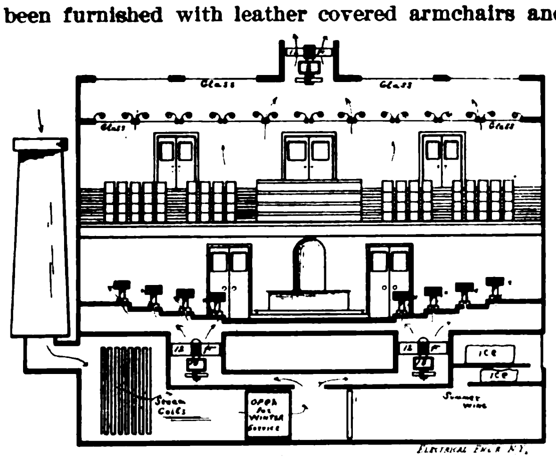
THE NEW ELECTRIC LIGHTING AND VENTILATING PLANTS AT THE U. S. CAPITOL.

BY NEVIL MONROE HOPKINS.

WHEN the Fifty-fifth Congress convenes on December 7, it will mark the inauguration of the extensive electric lighting and ventilating plants that have been installed during the past summer. The House of Representatives, Senate and Capitol grounds are to be brilliantly illuminated by the electric

THE U. S. SENATE CHAMBER.

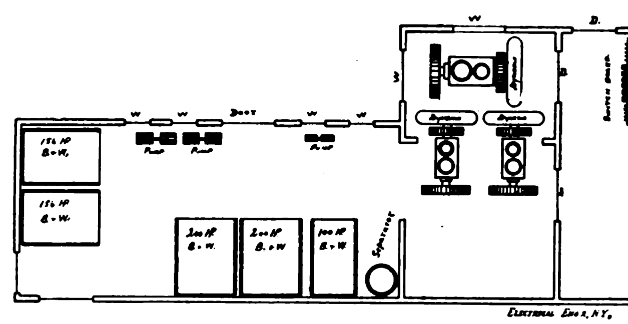
light, displacing the antiquated gas fixtures that have served during so many important proceedings. Not only has the Senate been furnished with the electric light, but the galleries have been furnished with leather covered armchairs and the



PLAN OF U. S. SENATE ELECTRIC LIGHTING PLANT, NATIONAL CAPITOL.

historic chamber equipped with the most modern and approved system of ventilation. Both the House and Senate are lighted from the skylight the same as before the change in lighting systems, the gas burners being left in place to serve for melting the snow away from the glass roof which often darkens the floor below.

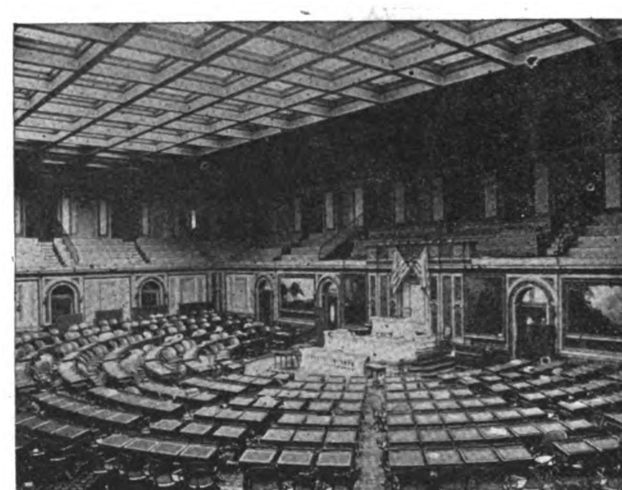
A general idea of the ventilating system can be formed from the illustrations, which illustrate the modern principle. The fans under the flooring are 12 feet in diameter and are driven by electric motors of 18 h. p. each. The fan on the roof is also 12 feet in diameter, but is connected to an 8 h. p. motor. The pure air is drawn from a stone tower situated on the northwest section of the Capitol grounds, and between



PLAN OF LIGHTING AND VENTILATING SYSTEM, U. S. SENATE, WASHINGTON.

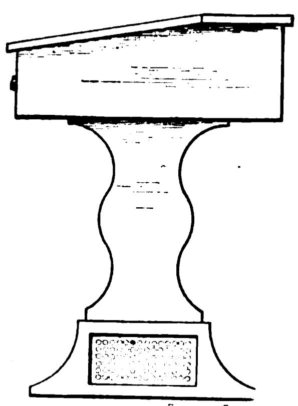
steam piping before it is driven up through the double, airtight flooring, and out in to the Senate through the perforations in the feet of the numerous desks. Each desk is provided with means of shutting off the supply of air or regulating it. An ice plant is to be installed later and means for cooling the air will be provided for sessions in warm weather.

The wiring throughout is on the two-wire system, incandescent as well as arc light being run on the same circuits. Arc lamps of the Manhattan incandescent type illuminate the grounds and are 150 in number. Owing to the numerous trees on the Capitol grounds it was quite a problem to place the lamps advantageously, but Mr. C. P. Gliem, electrician for the Capitol, has carefully plotted out the grounds and distributed his lights in an excellent manner. Mr. Gliem has also directed the wiring of the building and distribution of feeders, etc. In addition to the 900 incandescent lights that illuminate the Senate and the 1,100 in the House, many hundred are wired through the corridors and reception rooms.



THE U. S. HOUSE OF REPRESENTATIVES.

Descending to the basement one finds two entirely separate electric plants, almost identical in design and appearance, consisting of the same make of machinery and boilers. Our illustration shows a plan of the engines, dynamos and boilers on the Senate side. The boilers are all of the Babcock & Wilcox manufacture, furnishing steam at 100 pounds initial pressure, and aggregating over 800 horse-power. The two boilers on the extreme left of the diagram are used for heating the Senate and the corridors on the Senate side, while the House is equipped with a similar battery for warming the air in the other half of the building. The engines are of Westinghouse manufacture of the compound type and are run on condensers. The two placed side by side are of the same capacity, having cylinders 14" x 24" x 14", and run at 300 revolutions per minute, directly connected to generators of Westinghouse make, with six poles, 75 k. w. capacity, and wound for 110 volts pressure. The third engine and generator shown at the back, furnishes 187 k. w. also at 110 volts, revolving at the rate of 250 turns per minute, the generator having eight poles and the engine cylinders measuring 18" x 30" x 16". The switchboard is not yet permanently in position, but will measure about 8 x 12 feet, of white marble, 2¼ inches thick, equipped with Westinghouse indicating instruments. Our photograph of the Senate was taken before the alterations were commenced, and a visitor familiar with the old chamber, on entering during the day, would probably make no comments beyond speaking of the armchairs in the gallery that have taken the place of the former wooden benches. The cost of these alterations is $55,000, for which an appropriation was made at the last session of Congress. Should the heating and



End View, Ventilating Desk, U. S. Senate.

ventilation prove to be all that is expected, a duplicate installation will in all probability be voted for installation in the House of Representatives.

THE GENEVA ELECTRICAL WORKS.[1]

BY J. E. PETAVEL.

THE use of water as a motive power dates further back in Geneva than in most other towns. This is accounted for by its position at the overflow of a natural millpond of some 223 square miles in area. As early as 1708 the town was provided with a complete hydraulic station, while various mills and factories already occupied the banks of the river. In 1886 all the previously existing water-wheels were finally swept away, and one large central station erected, capable of utilizing the whole power of the Rhone at its outflow from the lake. Part of the 3,780 horse-power thus available was utilized for the water supply of the town, the main portion, however, being distributed as motive power by a network of high-pressure water mains. In a very few years the demand for power had risen to nearly the full capacity of the station, and to meet future requirements the municipality decided to erect a new station at Chèvres, some four miles further down the river, the estimated cost being $1,200,000. It was with the construction and working of this station that we now propose to deal.

The current of the Rhone beyond Geneva is rendered extremely variable by the influx of the waters of the Arve. In summer, when the mountain snows are melting, the flow may attain to 32,000 cubic feet per second; but to prevent inundations the head of water is not allowed to rise above 14 feet 9 inches. In winter, on the contrary, the flow of the river is reduced to 4,200 cubic feet, and the whole of the water passes through the turbines under a head of 27 feet 11 inches.

[1] London "Electrician."

To satisfy these widely varying conditions, a special design of turbine had to be adopted.

The weir consists of seven massive concrete piles, 9 feet 10 inches in width and 56 feet in length, rising to 31 feet above the sill. Supported on a series of pillars at a height

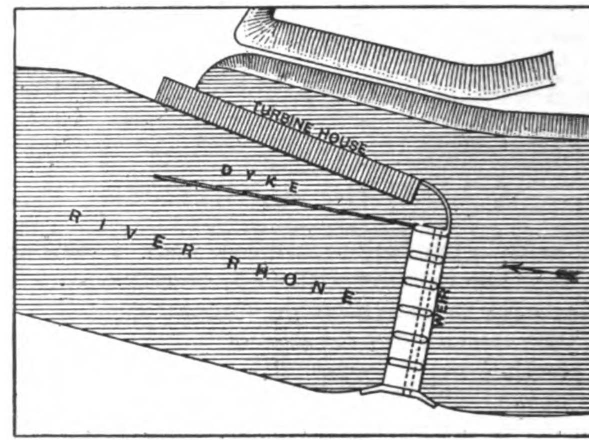


Fig. 1.—Chevres Station, Geneva Electrical Works.

of 16 feet above the top of the piles, is a bridge, on which is placed the necessary machinery for raising and lowering the seven sluices. These are 28 feet high and 33 feet wide. They move on a series of rollers, and are balanced with an iron counterweight of 50 tons. Thanks to this mechanism, two men can easily work them, even when the pressure on their surface rises to 360 tons. M. Turrettini, the chief engineer of the Chèvres works, adopted for these sluices the design he had seen in use on the Manchester Ship Canal. The dyke shown in Fig. 1 prevents the rush of water from the weir from raising the level of the water in the tailrace of the turbines. The power house when completed will contain 15 sets of turbines, each set being capable of giving from 800 to 1,200 horse-power, according to the level of the water; thus the total power of the station will not be less than 12,000 horse-power.

The difficulty we have already pointed out with regard to the design of the turbines was overcome in the following manner: Two complete turbines were placed one above the other on the same shaft, the lower one alone being used in winter, when the available quantity of water is small. This turbine can give up to 1,200 horse-power, under a head of 28 feet, the full load efficiency being 75 per cent. Under a head of 14 feet 9 inches this same turbine only gives 400 horse-power, and it is then that the upper one is brought into use to make up a total of 800 horse-power. To allow for

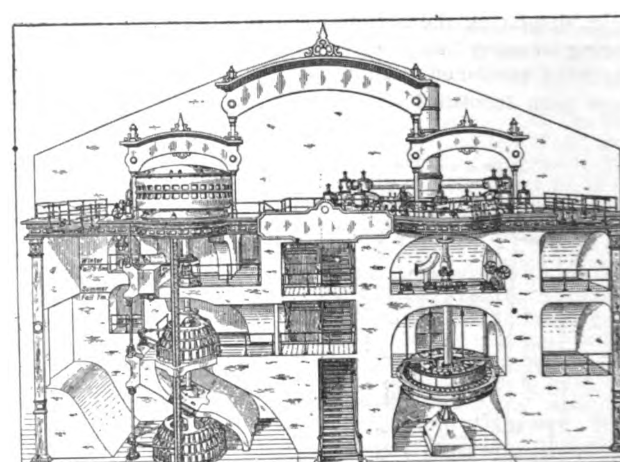

Fig. 2.—View of Full-Size Model of Geneva New Electrical Works.

the passage of a sufficient quantity of water without increasing the external diameter, and therefore decreasing the angular speed, the vanes and guides are disposed in three stories on three concentric circles, thus giving to each turbine the appearance of a large cone. The view shown in Fig. 2 will give a clearer idea of the turbines and alternator employed than any lengthy description we could give. It is taken from a full-sized model placed in the Geneva Exhibition. On

the left-hand side we see the plant used at Chèvres, and on the right a turbine of the pumping station of the town to which we refer at the beginning of this article. Since the close of the exhibition these turbines are being fitted up at their respective stations.

The Chèvres turbines are provided with a regulator so arranged that a very small angular motion will entirely cut off the water, and thus rapidity of action is secured. An ordinary centrifugal governor actuates a small slide-valve, which admits oil under a pressure of 15 atmospheres to one side or the other of a piston, this piston in turn governing the regulator.

The top of the main shaft supports a large cast-iron bell, 14 feet 9 inches in diameter, which, as we shall see later, takes the place of the field-magnet of the alternator. The total weight of the movable part is about 30 tons, rising with the pressure of the water on the vanes to 40 or 50 tons under full load. The method adopted to prevent excessive friction is worthy of note. The main shaft carries a large disc, ground perfectly true on its lower surface. This disc bears on another, which forms part of the bed-plate of the alternator. Before starting the turbines, oil, under a pressure of about 15 atmospheres, is forced between these two discs, thus lifting the shaft a few thousandths of an inch, and floating the whole revolving mass on a surface of oil. Under these circumstances the friction is so much reduced that one man can set the alternator in motion. Three sets of pumps, driven by electric motors placed on the exciter-circuit, force the oil into

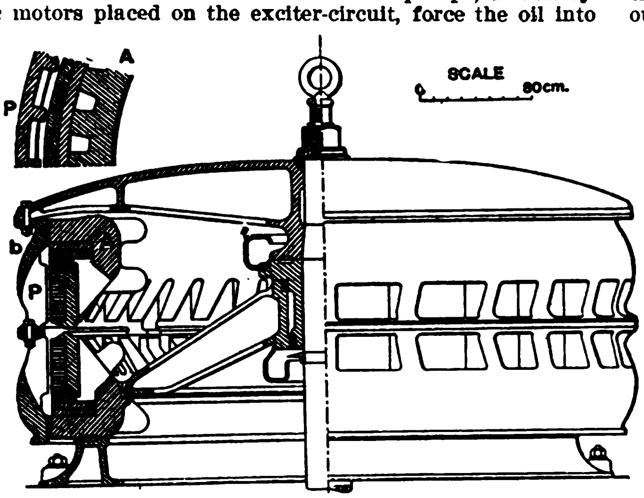

FIG. 3.—ALTERNATOR, GENEVA ELECTRICAL WORKS.

an accumulator, where a pressure varying from 12 to 25 atmospheres is maintained. This accumulator can supply the necessary flow of oil for a few minutes should a breakdown of the pumps occur. These pumps will in time be replaced by a set forcing a constant flow of oil through each turbine, the pressure adapting itself automatically to the weight of the moving parts.

The principal point of interest lies in the fact that both field-magnet coils and the armature windings are stationary. The alternator is double, each half forming a complete machine and giving one phase. It is so constructed that by changing the relative positions in which the upper and lower halves of the bell-shaped inductor are bolted together, the two phases can be brought into synchronism.

Referring to Fig. 3, we will limit ourselves to describing the upper half of the alternator. The fixed part of the magnetic circuit is formed by an iron ring, A, in which a space has been reserved for the field-magnet coils.

We may note in passing the way in which these coils were wound. A circular rail was laid round the alternator already erected in position. On this line, a truck worked by a small electric motor ran round and round, winding the coil as it went.

The lower face of the ring A is made of laminated iron, and on this are placed the armature coils. Opposite this face, and forming part of the bell, are a number of polar projections, P. These poles, as they revolve, carry round the magnetic field, thus producing the desired electromotive force. The magnetic circuit is completed by the side, b, of the bell and the upper part of the ring.

The tests of the first alternators, though quite satisfactory in other respects, showed the electromotive force to be very much lower than the calculations had led to expect. This was attributed to the presence of a small percentage of manganese in the composition of the iron.

The transmission line is about four miles in length, and entirely underground. The conductors are laid in a concrete conduit 15¾ inches wide by 11¾ inches deep, the flooring being 2 feet 4 inches below the surface of the soil. Walls and floor are first coated with an insulating preparation of tar, then bare copper conductors are stretched over porcelain insulators placed at intervals of 2 feet along the line, and the conduit is filled up with asphalt concrete, poured in at a temperature of 200° C. In the upper part of the conduit, seen in Fig. 4, are three small cables containing the telephone and pilot wires. The whole of this work is protected by a concrete cover. The pressure on the line is 3,000 volts, and for the first few months the insulation did not prove as satisfactory as had been hoped. Of late, however, the condition of the line has greatly improved. To ascertain the position of any fault, two men walk along above the conduit, each holding an iron staff, connected by a wire some 20 or 30 yards long. In this circuit is inserted a telephone, which immediately signals the existence of a fault. Four lines were necessary; each one consists of seven cables, and each cable of seven wires 3.6mm. in diameter. The cross section of one of the lines is, therefore, 0.76 square inches.

The centre of the town of Geneva has already, for several years past, been supplied with continuous current on the three-wire system; the pressure adopted is 2x110 volts. The older dynamos are now being replaced by a set of rotary transformers utilizing the power received from Chèvres. The outskirts of the town are provided with alternating current

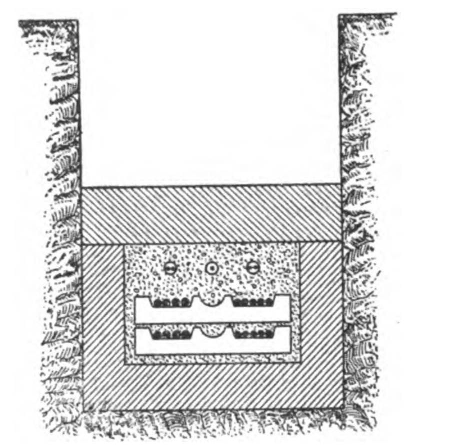

FIG. 4.—ELECTRIC CONDUIT, GENEVA.

by a number of small transformer stations. Three wires are used, the motors and lamps being so distributed as to keep the load on the two phases as equal as possible.

It is on the low-pressure alternating-current network that the 150 arc lamps, which light the principal streets of the town, are placed. A separate transformer is used for each lamp.

A number of tramway lines radiate in all directions round Geneva. Eight or ten of these have been constructed within the last few years, and several are already being worked on the overhead trolley system. The experiment having proved thoroughly satisfactory, the other lines will in all probability shortly follow suit. The municipality furnishes power to the tramway company at the exceptionally low rate of 2.30 c. per kilowatt-hour.

The electrical works we have just described were carried out by the Compagnie de l'Industrie Electrique of Geneva, and our thanks are due to MM. R. Thury and A. Graizier for the valuable information they have kindly furnished.

SPRINGFIELD, MASS.—Trouble has arisen over the frequent outages of street lights, and the street light committee has been holding up the bills. Mr. H. S. Anderson, manager of the Electric Light Company, claims that the average time each light has been out during a month is only three-tenths of 1 per cent., which is lower than the general New England average of four to six-tenths, excepting Worcester, where it runs about a quarter of 1 per cent. He said that "if lamps could be had which would not go out so easily, it would well pay the company to put them in, as then they would save part of the cost of inspection."

MR. WILLIS A. ROTH, of Buffalo, has been appointed electrician of the Long Island State Hospital, at Brooklyn, from the civil service eligible list, at a salary of $900 a year.

STUDIES IN THE SPECTRUM OF REFLECTION.—II.

BY DR. W. H. BICHMORE.

BUT after all what is the purpose of all this study, what justification is there for this labor, in a word, what is its practical bearing? Just this, we are dealing scientifically and commercially with a method of illumination in which a large sum of money is invested. This method has no natural monopoly of the business; far from it, to-day it stands head and shoulders above its competitors. But how will it stand this day week? They are hardly rivals, and yet at times they run it closely. The Welsbach mantle offers a volume of light simply enormous, and when the objections to it are either unknown or ignored, has a foothold and a following which promises to be permanent if not to increase. There are other projects for using the power of electricity, as a means of obtaining light; some have had a quasi exploitation, some are only laboratory experiments, but any day may see attacks made from unexpected positions by unsuspected foes, and it is the duty of every one who is directly or indirectly interested in defending our industry to know all we can that we may the better do our duty in the hour of need.

Clearly therefore, leaving the task of bettering the lamps to those whom it may concern, we must use every effort to get all we can from the lamps as they stand, and use every justifiable means of making others use the lamps to the best advantage.

It seems almost gratuitous to say that the pressure must be held up or the lamps will not give the light they should, for they will not get hot, yet there are dozens of buildings in New York City where, if the current is measured as it comes from the lamps, it will be found to be underrun. Nothing is more simple than to try it, and nothing is more convincing than the result. When anyone complains, the usual procedure is to remove the lamp and screw in a new one, and the public has gathered the impression that the lamps are at fault when they are nothing of the kind. But there is equally no possible sense in over-supply; this also is done. There is one building in Broadway in which the lamps "burn blue," and neuralgia is the order of the day.

When the stenographer and type-written matter is in evidence this is the worst fault of the twain, for the paper and ink approach too closely in their reflection spectra under such conditions for any good to follow increased illumination. But it is by simply teaching the public how best they can use what they have that the greatest progress can be made.

It is quite curious to note the differences in detail of samples of paper, of ink, of ten thousand things in this regard, all of which have bearing not to be neglected. In that theory of color for which Fraunhofer and Brewster are responsible, the legitimacy of the use of the color for what we call black and white is vigorously denied. Yet there is no rational doubt that this theory of color hinders the best use of lamps by many who are unconscious of its influence, and certainly could not state it correctly if they were to try. To most people the statement that white is the presence of all color and black is the absence is true, because it is orthodox, but such a black and white no human being would know as such if he saw it, nor would he ever see it, for equally neither could bring sense image to him; each alike would be a contrastless whole, an indistinguishable void.

"The whitest whites,, known to the arts are iron free kaolin and barium sulphate, yet spectroscopically they are both of them greens, and the black of lamp black is a shade of red while that of plumbago is a blue. It is this misconception which baffles so many efforts, colors must be studied under different auspices, and with a different purpose in view than the usual one; rooms must be finished not simply to please the eye by day, but to gratify the sense of rest by night.

The real question is how shall we meet the blue of our lamps? Every school boy who has studied Ganot's "Physics" knows that if two sun spectra be crossed at right angles, the blue and yellow mutually neutralized show white, and that against a bright ground of this color a small square of spectral red and green superposed shows black.

Reducing the facts to their exact bearing, it may be said that the sum of the waves from 6,460 to 5,945 added to those between 4,895 and 4,600 present, when exposed against those between 5,945 and 4,895 added to those between 4,600 and 4,307, the strongest possible contrast. Here lies a remedy for much of our complaint: the adoption of a yellow-blue combination as white which will give a maximum reflection and consequently a maximum illumination when subjected to the blue-green combination with the yellow which is the brightest light of incandescent carbon.

Familiar examples of this thing are the Winsor and Newton and Reynolds patent bristol boards. Winsor and Newton is rather too blue, Reynolds too yellow for criteria, but by the incandescent filament one is a deep dead white into which one may almost see, the other a brilliant superficial one which seems almost to shine. Again and again have I measured the spectra of reflection, again and again have I in wonder asked myself why so small a difference parts them so sensibly.

The most perfect white among papers which I have studied is that of a drawing paper by Harding. So little superficial reflection was there that after stretching, the absorption bands in colors put upon it were plainly to be distinguished, yet it reflected light with an equality of action to which that of barium sulphate is alone to be preferred.

In white pigments I find that among surfaces rubbed down with pumice stone, white zinc gives an unexpectedly high result, better indeed than unmixed white (carbonate) of lead; sulphate of lead stands very high, but neither equals barium sulphate. This was specially interesting, because some time since I chanced to examine very carefully a sample of lead paint, "pure white lead," as usual, carefully adulterated with barium sulphate by the Erni process, which had the highest uniform index of any paint I have ever seen. It is beside the subject in a way, but excepting compressed barium sulphate made in tablets for the purpose, I have no knowledge of any white surface approaching so near a theoretical white as this. Ordinary hard finish is not in the list with it. If the barium adulterated paint were only openly sold as such and were put on and surfaced as this specimen was, it would be the most perfect white for interior work known to me.

Barium sulphate mixed with just enough plaster of paris to hold it wet and allowed to set, also makes a magnificent reflection surface for all very hot carbon lights, but it will not stand, at least my endeavors to make it do so have failed.

Taken in their order of performance values, illuminated by incandescent filament lamps running under full voltage, these pigments run: Barium sulphate, iron free kaolin, sulphate of lead containing barium sulphate, oxide of zinc (Chinese white), common white lead prepared by the "new process" which is a sulphate, and common white lead prepared by the "old process," which is a carbonate. Next to these, but also showing white to the unaided eye when illuminated by the incandescent filament, come two series of colors belonging to quite different groups, one having an excess of yellow reflection by sunlight, the other an excess of blue.

Of these yellows the first is ordinary zinc white, this is deficient in general reflection capacity, but reflects excess of yellow as stated. With it ranks a sulphide of cadmium, a most extra brilliant pigment considered in this connection and the third I have purchased as "lead yellow," but have not troubled myself about it further. These three pigments present the peculiar relations of an underrun and overrun circuit crucially; indeed the color which cadmium sulphide takes is a very crux for the lamps. When the lamps are getting their full allowance of the current, the sulphide of cadmium shows white, an ivory hue beautiful and dazzling in its brilliancy; but let the voltage fall never so little and a wretched guy takes its place, closely resembling that produced by washing a piece of Whatman Not with an exceedingly thin wash of neutral tint and following that with an equally attenuated wash of gamboge. The water-colorist can tell many a tale of disappointment due solely to these irregularities of the current, and more than one sworn foe of the filament lamp, and equally sworn friend of the "mantle" dates his change of heart to an experience of the sort suggested.

The blue-greens, "peacock tints," and the true yellow green of the spectrum obtained by imitative color-pigment present changes quite as striking but in inverse order. These also are modified by the changes in hue of the emission, but the whitening from the underrun circuit is less interesting than the change called up by the excess of the blue reflection. It will be noticed that among the illumination curves plotted there are a pair in which the illumination by electric light exceeds the illumination by daylight. As was mentioned in the previous chapter, this paper is a blue-green one, and it requires for its best illumination just the colored light the fully .heated incandescent filament emits. Working along these lines to enlarge the list I found that the group which gives this illumination most nearly are green-blues made with cobalt and raw sienna. Why this group illuminates better than Prussian blue and raw sienna I do not know, but that they do illuminate I do know. If the use of blues and greens of this tint can be widely encouraged, it will add to the needs of all a new relief, but there are drawbacks. This reflected blue-green guys all colors not itself and, like time, changes all things to a monotone, and an unpleasing one. The resulting effect to all bright lines not peacock tints is a saddening one. I can give no list of pigments as I gave under whites,

for these tints are all mixed ones, but I can mention one or two curious facts. The pigment known as viridian, i. e., the chromium oxide, is particularly ruined by this overrun illumination, while the deficiently warmed lamp is much less injurious to its hue.

I do not by any means consider this subject as exhausted, but I think enough has been written to show the importance of knowing in advance how hot the lamps will be, and considering what effect the light they give will have on the color of things in the room.

NEW YORK STATE CONTROL.

Assemblyman H. E. Abell, of Brooklyn, is to introduce a bill in the next Legislature placing all the gas, electric light, telegraph and telephone companies under the supervision of a State Commission, after the manner of the Commissions on banks, insurance and railways.

MUNICIPAL LIGHTING DISCONTENT AT JACKSONVILLE, FLA.

There has been considerable complaint for several nights about the city electric lights being out, and there is talk of enjoining the city from running on a so-called moonlight schedule.

LAMP-TRIMMING AT FLATBUSH, N. Y.

The lamp trimmers of the Flatbush Electric Light Company, Long Island, complain of having too many lamps to trim since the city lighting was increased in that suburb. The men claim that they have as many as ninety lamps apiece to look after daily, scattered over ten miles of street. They get $12 a week. Supt. Conklin does not consider them hard-worked.

NEW LIGHTING CONTRACT FOR JERSEY CITY, N. J.

The Street and Water Commissioners of Jersey City have made a five-year contract with the Jersey City Electric Light Company for the lighting of the city by electricity. The contract is considered an unusually favorable one by the officials. Under the contract just made one thousand electric lamps will be furnished during the ensuing fiscal year and from then until the expiration of the contract not less than nine hundred are to be furnished, all over that number being governed entirely by the appropriation made for street-lighting purposes. The precaution was taken not to fix one thousand lamps for the whole term in order to meet with any possible sweeping reduction in the appropriation which is now $123,800 a year. When bids for the lighting of the city were called for the Street and Water Commissioners reserved the right to make a one, three or five-year contract with the lowest bidder. It was found that under the prices submitted for the one and three-year contracts, provision being made for three hundred gas lamps and seven hundred oil lamps, that the appropriation would be overdrawn if nine hundred electric lights were to be furnished. Under the five-year prices, however, that difficulty was overcome. On the basis of nine hundred lights the Jersey City Electric Light Company agreed to furnish each light at $99 a year. Allowing that one thousand lamps are used during the term of contract the annual cost will be $99,000. The gas and oil lamps, reglazing and furnishing of necessary supplies will cost about $23,300, which will still leave a margin in the appropriation of $123,800 of $800 for emergencies. It is shown by the commissioners that in contracting for five years instead of one year the city saves $9,900, and $6,300 is saved by making the long term contract instead of three years.

A STUDENT TAMPERS WITH A LIGHTING PLANT.

There have been troubles of late in the Warwick Electric Company at Wellington, O., which operates a plant. A college student when arrested made a confession that he and others had destroyed machines belonging to the system for lighting the city and had stolen workmen's tools. It is said he was induced to do this by disgruntled stockholders, who wished to impede the receiver of the plant in the discharge of his duties.

MORRISTOWN, N. J.—The Morris County Electric Company is increasing its plant by the addition of a 650 horsepower Ball & Wood cross-compound engine fitted to run three 2,000 light generators. One new General Electric generator of 2,000 incandescent lights capacity, and possibly two, will be put in at once. Work has already been commenced and the plant will be in operation within a few weeks. A store house is also being erected on the lot on the easterly side of the railroad recently purchased by the company.

MISCELLANEOUS.

MAGNETIC SURVEY OF MARYLAND.

THE Maryland Geological Survey, in an endeavor to make its work fundamental and at the same time of the greatest value to the material interests of the State, has taken up, in its preliminary investigations, a thorough study of the magnetic conditions affecting that portion of the earth's crust within the borders of Maryland. In addition to the far-reaching importance of this work upon the future observations and determinations of the great rock masses contained within our State, these investigations will be of immediate practical benefit to all land surveyors, and from that standpoint alone will more than justify the undertaking.

The investigations are being conducted under the direction of the State Geologist by Dr. L. A. Bauer, who is in charge of the department of terrestrial magnetism in the University of Chicago and was for some years prior thereto connected with the Coast and Geodetic Survey in Washington. By the courtesy of the Secretary of the Treasury the costly apparatus in the possession of the Coast and Geodetic Survey has been placed at the disposal of the Geological Survey of Maryland during the summer and autumn months of the present year, an arrangement which has alone made the work possible. At the same time the American Association for the Advancement of Science has allotted to Dr. Bauer a sum of money to aid in carrying on the investigations. It will thus be seen that much support has been secured from outside.

A magnetic survey involves the determination at a number of points of the so-called magnetic elements, viz., the magnetic declination, the magnetic inclination or dip, and the horizontal component of the earth's magnetic force. These three elements completely determine the direction and intensity of the magnetic force prevailing at those points.

Magnetic declination, or, as the mariners and surveyors frequently term it, variation of the compass, involves, first, the determination of the true north and south line, which is obtained by astronomical means alone, and, second, the determination of the magnetic north and south line, which is the direction taken by the compass needle. The magnetic declination is the angle between these two lines, and is recorded as so many degrees east or west of north. In Maryland this angle varies from about 6 deg. west in the northeastern corner of the State to about 2 deg. west in the northwestern part. This is the element which chiefly concerns the land surveyor, but which he is rarely, if ever, able to independently determine.

Magnetic inclination is the angle of dip, which, in our hemisphere, the needle makes below the horizontal plane, the needle being placed upon a horizontal axis and moving in a vertical plane through the magnetic north and south line.

The horizontal component of the earth's magnetic force is further determined by a specially constructed magnetic needle, the time of vibration being obtained under the influence of the earth's magnetic force in combination with the angle of deflection which this magnet produces on another magnet at a given distance. This gives the absolute value of the horizontal component, while relative values may be obtained at the same time by referring the observations taken to a central base station.

The importance of magnetic surveys has been recognized for many years, the first survey of this kind having been made in England in 1837 and the third survey having but just been completed in that country. Surveys have also been made in several of the other European countries, although little systematic investigation in this direction has as yet been undertaken in America. Some preliminary work has already been done in Missouri, Pennsylvania and Iowa, while the United States Coast and Geodetic Survey has made observations at widely separated points. Nowhere in this country has such systematic and complete observations been taken as in the magnetic survey of Maryland. About forty stations in all have been established, or one for about every 250 square miles, which entitles Maryland to the claim for making by far the most detailed magnetic survey yet undertaken in America. The proximity of the Magnetic Observatory in Washington will largely add to the value of the work, as the observations made in Maryland can be readily compared with the continuous records of this observatory. By means of the observations thus far made preliminary iso-magnetic maps for the State can be constructed in the form of isogonic, isoclinic, and isodynamic charts showing areas of like magnetic declination, inclination and force.

It will be of great interest and value to decipher the magnitude of the disturbing forces. For this purpose the northerly, westerly, and vertical components of the earth's magnetic

forces will be computed at each of the points of observation, and from this will be subtracted the values due to that part of the earth's magnetism which can be referred to a homogeneous magnetization. These residual quantities will show the complex distribution of the earth's magnetism and afford the basis for important scientific conclusions.

ELECTRICITY IN NAVAL LIFE.—IX.

BY LIEUT. B. A. FISKE, U. S. N.

AZIMUTH TELEGRAPHS.

FOR telegraphing azimuths, or ranges varying between, say, 0 and 12,000 yards, for connecting position-finders to the gun, or relocator positions in forts, or for any other class of work in which many separate signals are required, the system is extended as indicated in Fig. 26, A. It simply amounts to using two transmitters and two receivers on separate circuits. One transmitter and its receiver are graduated in degrees, while the other transmitter and its receiver are graduated in minutes. Angles as high as 120 degrees can by this method be telegraphed with great quickness and extreme accuracy, that is, with errors of much less than one minute of arc.

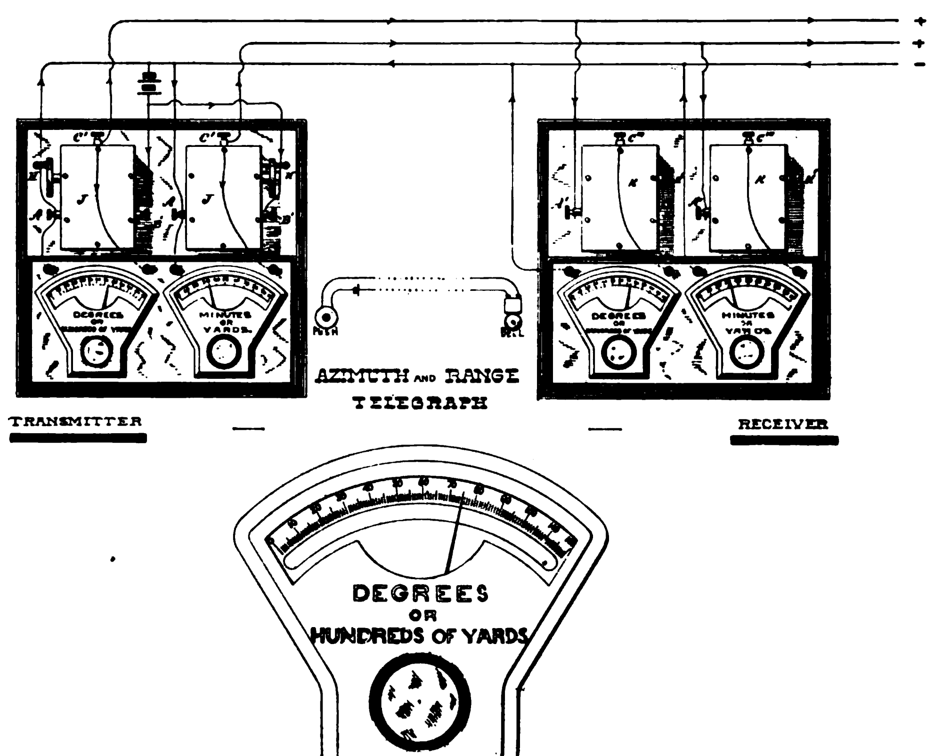

FIG. 26A.—AZIMUTH AND RANGE TELEGRAPH.

For signaling ranges which must be correct within one yard, between 12,000 yards and 0, the same plan can be used, except that the 120 graduations of the left-hand galvanometer mean, not degrees, but hundreds of yards; while the divisions on the right-hand galvanometer mean, not minutes of arc, but single yards.

Besides the accuracy and quickness of this system of telegraphing, one important advantage is that the circuit is always closed, so that all the connections and contacts are always made, and there is no making and breaking of the circuit. All the connections may be made ten times as strong and big and firm as is necessary, and even then they will not be very big, or take up much room; so that, if the system is kept in anything approaching good order. it will never break down in an emergency.

The same system can be used to telegraph orders to the turrets, torpedo-positions, gun positions, and other parts of a ship, as it is merely necessary to graduate the dials of the indicators suitably, in some such way, for instance, as that shown in Fig. 26, B. The system is about to be tried in the U. S. armored cruiser Brooklyn, for transmitting battle orders from the conning-tower to the forward and after turrets, the dials indicating such orders as a captain would wish to give to the

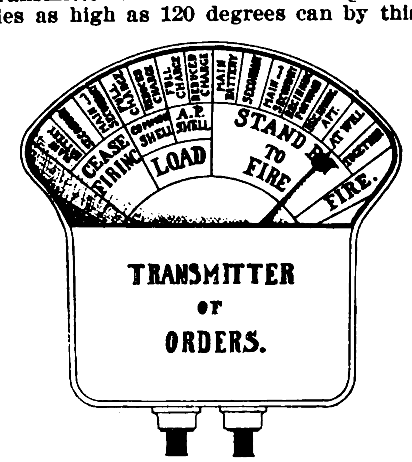

FIG. 26B.—TRANSMITTER OF ORDERS.

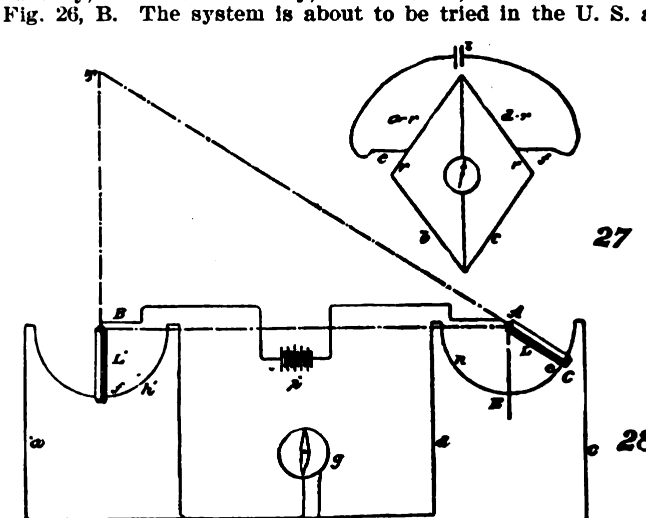

FIGS. 27 AND 28. THE RANGE FINDER.

turrets in an action, when noise would make audible signals impossible.

This instrument has now been tested for somewhat more than five years and has finally been adopted by the United States Navy. It has naturally undergone some changes during the process of evolution, and we now show the form which it has finally assumed. It will be remembered that the instrument is based, as far as the general principle goes, on the measurement of resistances of a conductor, in the form of a Wheatstone bridge, there being two arcs of wire at the ends of a base line, each arc corresponding to two contiguous members of the bridge. Two telescopes are located at the ends of the base line and carry contacts which move over the wire as the telescopes are turned in angle, to be pointed upon any object.

Let Fig. 28 represent the arms a and b of a Wheatstone bridge bent into the form of an arc h′, while c and d are bent into the form of an arc h, both of these arcs being wires of conducting material. Let telescopes, pivoted at A and B, be fitted with the contacts e and f. Now, if the extremities of the semi-circular arcs are in the same line, the contacts carried by the telescopes will press on the middle parts of their respective arcs, and the galvanometer will, therefore, not deflect, whenever the telescopes are parallel and at right angles to the base line, because ac = bd. But when the telescopes are parallel they are directed at some point in space infinitely distant; that is, the distance of the object towards which the telescopes are directed is infinite. The position of rest of the galvanometer needle is therefore marked "Infinity."

Now, let the telescopes be directed at some point T not infinitely distant. The telescopes will converge and the angle of convergence is clearly the angle ATB, or the angle CAE, which is measured by the arc CE. In other words, the degree of convergence is measured by the difference in the positions of the contacts of the telescopes on their respective arcs.

But, if the bridge was in balance when both contacts were at the middle points, it will clearly not be in balance when one is at the middle point of its arc and the other at C; and the amount by which it is out of balance will clearly vary with this difference of positions. That is, the greater the amount of convergence of the telescopes, the greater the deflection of the galvanometer; so that the deflection of the galvanometer varies with the angle ATB. By trigonometry,—

$$AT = \frac{AB}{\sin ATB} \times \sin ABT.$$

From this formula it is plain that, if ABT be a right angle, the distance AT varies inversely with the sine ATB; and it is, therefore, plain that, if the electro-motive force of the battery remains constant, the deflections of the galvanometer vary inversely with the distance; so that, if we know the length of base, we may graduate the galvanometer directly in units of distance, remembering that with such small angles as ATB always is in range-finding, the sine of the angle is practically the same as the arc.

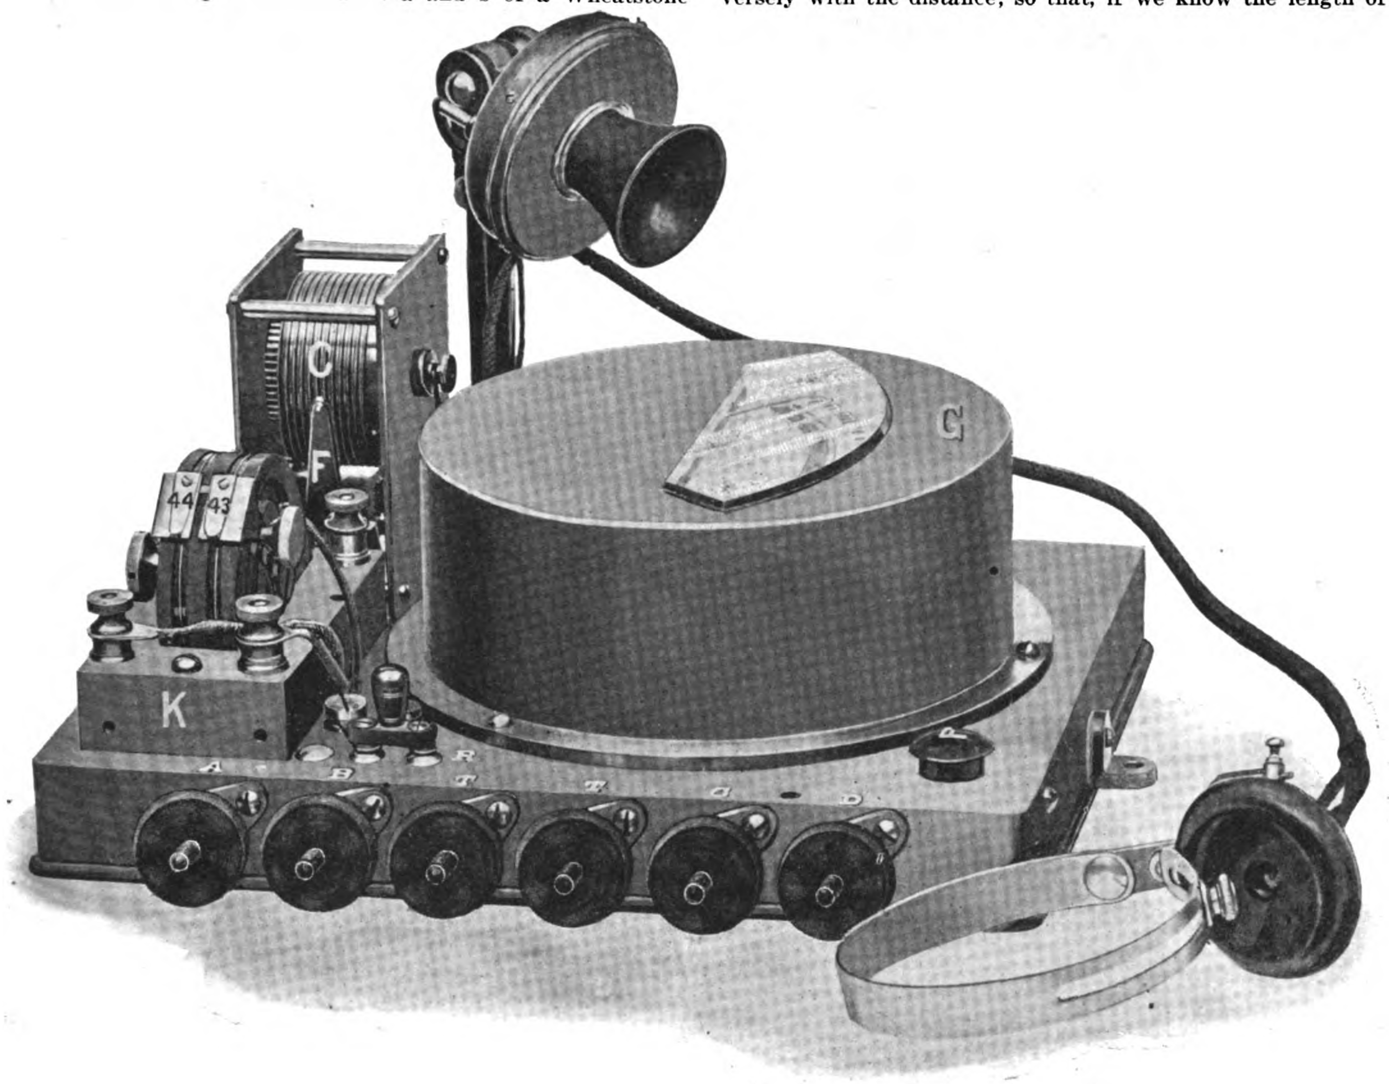

FIG. 32.—READING INSTRUMENT, RANGE FINDER.

But suppose that ABT is not a right angle. Suppose, first, that the target pointed at by the telescopes is infinitely distant, but in a direction inclined to the base. The contacts carried by the telescopes will not now press on the middle points of their arcs, but on points equally removed from the middle points. This is evidently the condition shown in Fig. 27, where the contacts have been moved away from the middle points over equal resistances. The galvanometer will not deflect, but will remain at its position of rest, which position on the galvanometer is marked "Infinity."

Let one contact be now moved from its position so that the telescopes converge and point at some object not infinitely distant. The galvanometer will deflect. In order to indicate the true distance of the object, the galvanometer must now deflect, not in proportion to sin ATB, but in proportion to

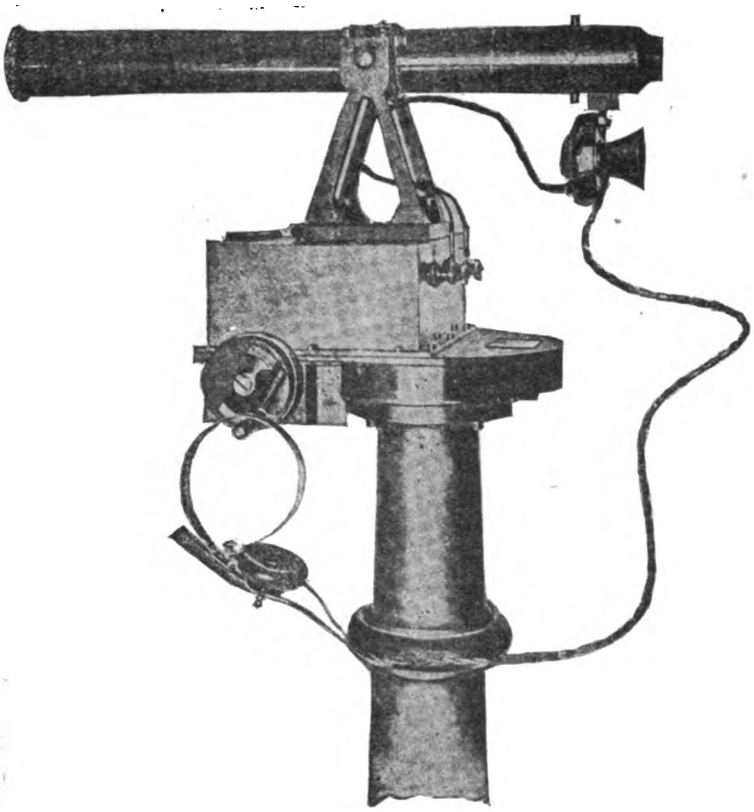

Fig. 29

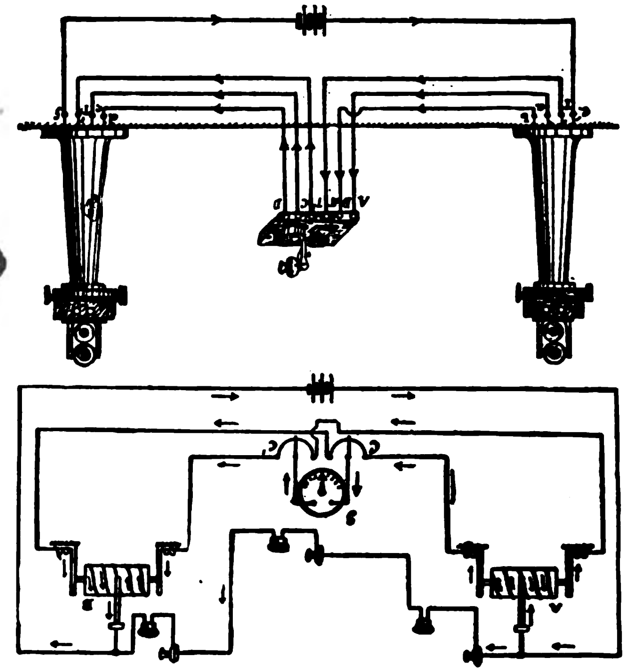

Figs. 30 and 31.

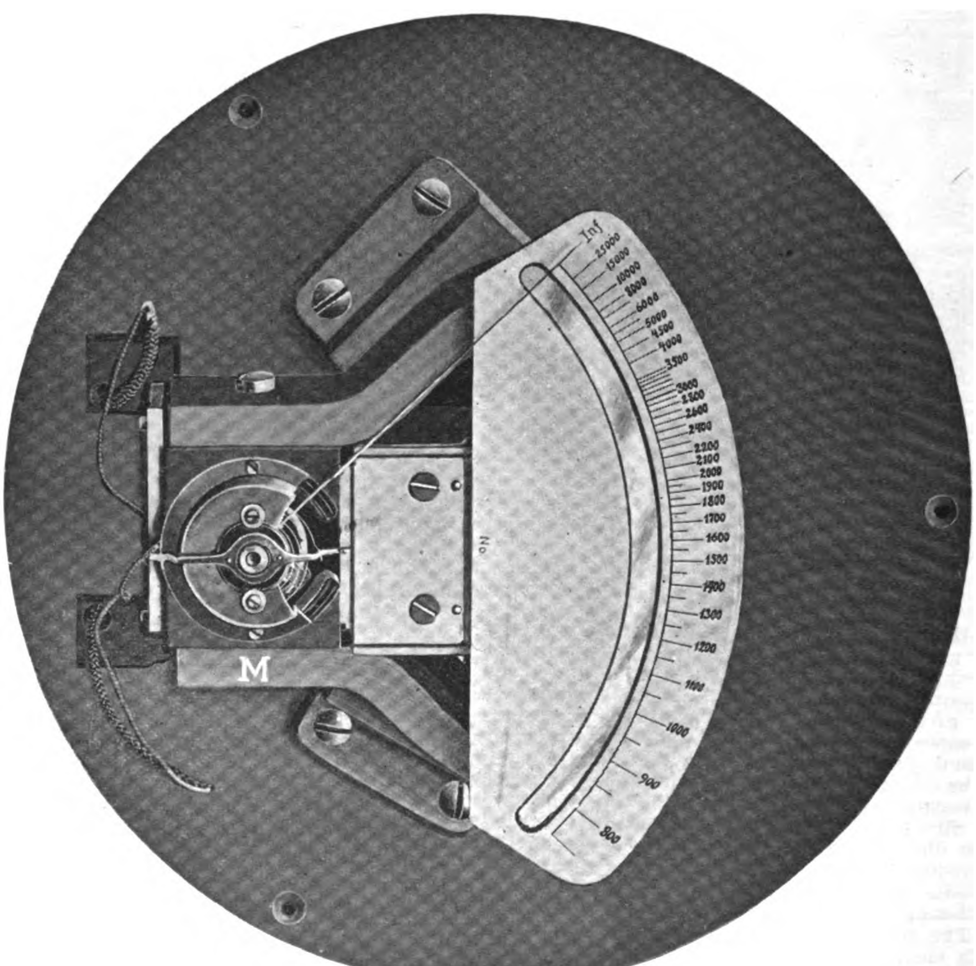

Fig. 33.—Interior of Galvanometer, Reading Instrument.

ATB ÷ sin ABT. In other words, it must deflect more for an angle of convergence ATB than if ABT were a right angle; and the smaller ABT is, the more the needle must deflect. In the range finder this increased movement of the needle is obtained by taking advantage of the curious fact that the current in the Wheatstone bridge increases as the contact points are moved away from the middle points. This is because the resistance of the bridge is less; so that, if the electro-motive force of the battery is constant, the current increases proportionally as the resistance decreases.

In the apparatus as at present constructed, the wire is not laid in the form of an arc, but is wound upon a cylinder of insulating material. A contact presses on this wire, and as the telescope above shown in Fig. 29, is turned in azimuth, the insulating cylinder revolves and causes the contact to press upon different parts of the wire. The special feature of value in this construction is that the wire is completely protected from the effects of weather, and, what is of more importance still, it makes it possible to use a device by which the non-uniformity of the wire is automatically corrected.

It has been said above that when the telescopes are parallel, and, therefore, pointing at some object infinitely distant, the contacts carried by the telescopes must press on the resistance wires at similar points; so that the galvanometer needle will not move from the infinity mark no matter at what angle the telescopes are pointed. In order that this may be always the case, it is evident that we must have an exact equality in resistance per unit length of resistance wires, or else we must have some device by which the non-uniformity will be corrected. This is accomplished in the instrument in question by a simple arrangement of the contact, by which, whenever the telescopes are directed at similar angles, the contacts automatically go to such parts of the wire that the bridge is in balance and the galvanometer indicates infinity.

Another important feature introduced in the present apparatus is a temperature corrector, by means of which any change of temperature, either in the climatic or other conditions, and its consequent effect upon the resistance of the circuit, is automatically compensated. In Fig. 30 the temperature corrector is shown at C C' and consists simply of two similar arcs of wire introduced in the circuit between the two observing instruments at the ends of the base line, upon which arcs press the contacts of the galvanometer G. In case the temperature of either instrument, say B, is raised and its resistance correspondingly raised it is simply necessary to move the two contacts of the galvanometer G along the arc C C', a distance sufficient to compensate for the increased resistance of that instrument. In order to tell when this sufficient distance has been traversed it is merely necessary to set both instruments at similar angles and move the two contacts equally on C C' until the galvanometer shows infinity.

This operation requires a few seconds only, and suffices to adjust the range finder for the temperature conditions which prevail that day. Fig. 31 shows a diagram of the circuit of the range finder. The two instruments at the opposite ends of the base line with their telescopes and telephones are shown. The arcs a and b of one instrument are connected to the arcs c and d of the other instrument, through the temperature corrector, which is mounted on the base of the reading instrument shown in the center. The telephones on the two observing instruments are connected together through the telephones on the reading instrument and the battery contacts are connected to the storage battery, shown below, which is ordinarily in the dynamo room of the ship. On the same base with the temperature corrector is the galvanometer or reading instrument. The captain of the range-finder crew is stationed in the conning-tower of the vessel or below the protective deck at the reading instrument and has all the devices for correcting the range finder under his hand. He has simply to see what figure the needle of the galvanometer points at and telegraph this figure to the guns, by means of the electric range indicator.

The details of the reading instrument are shown in Fig. 32; and the interior of the galvanometer, which is the principal part of the reading instrument, is represented in Fig. 33.

The shortest base lines with which this range finder has as yet been used successfully in practice, are in the New York and Indiana, in which the base lines are 46 and 44 yards respectively. In the Indiana, Massachusetts, Oregon and Texas, the forward observing instruments are mounted on a platform on the foremast, while the after instruments are at the after end of the superstructure. In the New York, both the observing instruments are on platforms on the masts; as is also the case in the Maine. In the other ships the observing instruments are usually secured on platforms built up from the deck, and on the conning-towers or pilot houses. In most ships, the reading instrument and the transmitter of the range indicator circuit are in the conning-tower; but in the Maine they are below the protective deck, which seems a better arrangement in a military sense. It would seem advantageous also to protect the observing instruments to at least as great an extent as the rapid fire guns. The average error, under conditions of service, with base lines of 45 yards, is about 1 per cent. for distances of 1,000 yards, 2 per cent. for distances of 2,000 yards, 3 per cent. for 3,000 yards, etc.

ELECTRIFYING A BIG BOILER IN TRANSIT.

A special dispatch from Calais, Me., of November 6, says: In Calais a huge boiler was being drawn through the streets to-day by sixteen horses, when the upper portion of it came in contact with overhead electric light wires, breaking them. Some of the wires caught on the boiler and the framework of the truck, and in an instant all the horses were knocked down. Several of them were killed. The men engaged in transporting the boiler received violent shocks, and several are dying. The accident caused consternation among the onlookers.

BICYCLE TRACK PUSH BUTTONS.

A new kind of bicycle race recently took place at Norway, Me. A board track 100 feet long and eight inches wide was built, and electric wires strung, with twenty-one buttons scattered along the length of the path. The contestants rode the narrow track and in passing ran over the buttons wherever possible. The winner managed to ring eleven of the twenty-one bells.

LETTERS TO THE EDITOR.

IS THE NUMBER OF ALTERNATING ARCS ON THE INCREASE?

In your issue of Oct. 7, you raise the question whether the number of alternating arc lamps in use is not increasing. This was called soon after to the attention of that department of our company under whose jurisdiction our lamp matters fall, with a request for a report.

The statistics covering sales of arc lamps revealed that at the present time the direct current long-burning arc lamp, seems to be most in demand. This is explained by the fact that the inducements of reduction in carbon expenses, and the saving in the item of trimming, have considerable weight with purchasers. The lamps have found an extensive use in lighting shop windows, theatre entrances, etc., heretofore lighted by incandescent lamps, and the same may be said of mill lighting—many orders having been received from silk, cotton and woolen mills, saw mills, paper mills, etc., etc.

A steady growing demand for alternating arc lamps was also shown, especially in the field of additions to and extensions of existing circuits. There are many cities and towns in this country in which two systems of lighting only are used—the series arc system and the alternating incandescent system. The arc lighting machines are invariably loaded to their utmost limit and any addition to the number of arc lamps would be undesirable if not impossible. On the other hand the alternating current machines do not carry their full load, and can, therefore, be called upon in case of further extension. This extension cannot, however, consist always of incandescent lamps, and the alternating arc lamp naturally solves one of the serious problems with which the station manager is called upon to cope.

More or less, perhaps rather more than less, difficulty has been experienced in developing a really good alternating current arc lamp. The nature of the arc lamp itself causes considerable humming, and as at first made, alternating current arc lamps were given to chatter beyond the bounds of tolerance when started. The lamp itself has also been considered as much more delicate to handle and more easily liable to get out of order than the ordinary lamp, and these beliefs, probably, more than anything else, may be considered as the explanation of the aloofness of the station manager.

But the demand existed, nevertheless, and each alternating current arc lamp connected to the circuits, served as valuable experience. Objectionable features were called to the attention of the manufacturers with that peculiar suavity which characterizes the station manager who sets up an ideal and cannot always obtain it—with the result that by a process of elimination the alternating current arc lamp has become a very excellent lamp.

Speaking for the General Electric Company, a very large number of its alternating current arc lamps were sold in 1896, and this number will probably be doubled in 1897. We, therefore, feel that we can concur with you in your belief that the alternating arc lamp is making great strides, although we are not yet prepared to say that relatively it is overtaking the direct current arc lamps. GENERAL ELECTRIC CO.

CONTENTS.

STORAGE BATTERY ROADS.

IT has long been a standing reproach to American electrical engineers that they have not succeeded in placing the storage battery on the same level of usefulness which has been found for it in Europe. This criticism has applied to the utilization of the battery in stationary as well as in railroad work. The causes which have operated to retard its progress in the United States are familiar to all who have followed the history of the art which, until quite recently has been, to say the least, a sad one. But it is gratifying to note the steady progress now being made in many directions in the introduction of storage batteries in central stations both for lighting and for railroad power work, while a distinct impetus has been given it in connection with isolated plants. It is no longer necessary, indeed, to cite European practice to convince our own central station managers of the economy which a storage battery can effect in any station subject to a variable load, as this has now been well established in the progressive stations in New York, Boston and elsewhere. But it is rather to another application of the storage battery that we desire to draw attention here and that is, to street car propulsion. A retrospective glance at this branch of work on American soil, it must be confessed, is not calculated to develop an exultant state of mind; but a strict analysis of the various experiments that have been made will, we believe, not be adequate to condemn the battery for this purpose; rather would it serve the very useful object of showing how not to do it. Let us, for a moment, rapidly review the situation. Beginning with a single car operated in Boston in 1887, all the experiments thus far attempted in the United States, with one or two exceptions, have been carried out with one or two cars. It is not within the nature of things that the economy of a storage car system can be even approximately predicated from the data furnished by the operation of such a small number of operating units, and hence, knowing the ingrained conservatism of street railway companies, the failure to introduce the storage battery need not be wondered at. Among the exceptions referred to above, the most extensive is the trial given to the system in New York several years ago when ten storage battery cars were operated for about six months. The exact figures on this attempt have never been made public, but it is safe to assume that the result was not sufficiently encouraging to the management to warrant a change in motive power. But even this more extended experiment was undertaken under conditions which could hardly have ensured success. To begin with, it will now be conceded, we believe, that the batteries were too light to cope successfully with the work they were called upon to do, while their construction, in the light of present practice, was not calculated to ensure longevity of the plates. Add to these disadvantages the fact that the cars were run on an old and battered track and over grades of considerable length and rise, and we have all the elements for a satisfactory explanation of an unsatisfactory failure in this case.

But at last we are to have what is believed to be the first real attempt to operate a storage battery street railway under conditions which are in every way favorable to success, and the description we give of the Englewood and Chicago road in this issue, gives a good idea of the manner in which the problem has been attacked. We have, to begin with, a power plant equipped with the most modern steam generating and utilizing apparatus which will be operated at practically a constant load, with every indication that an electrical horse power hour can be generated for 2 pounds of coal or less. The employment of three potentials obviates all unnecessary loss in rheostats or in the gassing of the batteries themselves, a by no means inconsiderable item in a large plant of this kind. Beyond the confines of the power house we find a track laid with 80-pound rails and ballasted with stone—truly ideal conditions, which will assuredly repay the interest on the investment in them by the power they will save in driving the car and in the freedom from shocks which the battery will enjoy. Add to this the level character of the road and we have almost perfect conditions for a storage battery railway. Barring the one uncertain factor, the life and cost of repairs of the battery cells, there would be nothing to prevent an unqualified prediction as to the success of this road; but even on this single point im-

portant as it is, one may look with confidence towards the outcome. The experience of the past has shown that a certain amount of metal is necessary to give the storage battery the requisite stability for this class of work and it may be assumed that the lesson has not been lost on the projectors of this road.

There has been no event in electric railroading since the introduction of the trolley itself, which will be watched with closer interest than this new Chicago enterprise. Its success seems fairly assured and if it is managed on the proper lines it will have a pronounced influence on future work of this kind. We wish those immediately interested in the experiment a full measure of success, but may be pardoned for venturing the hope that success in this instance may not lead to the undertaking of similar work where the conditions are not favorable or the equipment is not so thorough.

"ARE CENTRAL STATIONS DOOMED?"

UNDER the above somewhat startling head, the "Engineering Magazine" for December contains an article from the pen of Mr. Max Osterberg, which touches on a question that has of late furnished the text for writers both here and abroad. The question is one which will well bear discussion, as it may help to throw light on some points not heretofore fully considered in connection with the cost of operation of small isolated plants, while, on the other hand, it will serve to emphasize certain matters in central station operation which must sooner or later receive serious consideration.

In viewing the subject broadly one would suppose that to the central station would be conceded greater economy in generation of current while to the isolated, or block station, would be allowed the advantage due to the absence of heavy feeders, their attendant first cost and the loss entailed by them, in a word, the distribution losses. But Mr. Osterberg does not grant the central station even this advantage. He quotes Mr. Horatio A. Foster's able article in our pages, showing that it costs 5.4 cents to produce one kilowatt hour in some of our large central stations and then presents figures on a system of block stations, taking as a basis the supplying of an area of ten squares wide, that is, one hundred city blocks of fifty houses each, which area Mr. Osterberg places at "one-half square mile," a palpable slip of the pen, but which may have had an important influence on his estimates for the cost of feeders. On the assumption that the average house consumes 50 lamp hours per 24 hours, one block would require 2,500 lamp hours, or 137 kilowatt hours; or, allowing for necessary losses, 186½ kilowatt hours. Mr. Osterberg then assumes a coal consumption of 5 pounds of coal per horse-power hour, with coal at $3.25 per ton; attendance at $2.50 per day and oil, waste, etc., 50 cents, making a total daily expense of $4.81, or 2.31 cents per kilowatt hour. A similar calculation for gas at $1.25 per 1,000 cubic feet figures out at 4.22 cents per kilowatt hour. Mr. Osterberg concedes that in practice the figure he gives for operation with steam could not be reached, as no allowance was made by him for firemen's wages, the cost of banked fires, and for water tax, to which we may add the cost of repairs, depreciation, superintendence, cost of insurance of accumulators, and incidentals, all of which may materially alter his figures. Mr. Osterberg then goes into the calculation of the cost of an entire system of this kind. A single central station capable of furnishing the hundred city blocks with 250,000 lamp hours per day, with a fair chance of nearly 60,000 lamps burning at one time, that is, 30,000 amperes at 110 volts, would necessitate laying down a 4,500 horse-power plant. The feeder cost is placed at $500,000 laid; the site and construction of the power house at $500,000, and the boilers, engines and dynamos at $250,000 more; a total of $1,250,000. The cost of 100 block stations with gas engine and storage battery outfit is placed at from $12,000 to $15,000 apiece or $1,200,000 to $1,500,000; that is, about equal to that of the central station plant. Mr. Osterberg assumes that the cost of rent for these plants would be practically negligible inasmuch as the house in which the plant would be installed would be supplied with light at a proper rate, or would receive a certain amount towards the salary of the janitor, who would take care of the plant, for which each building would be charged pro rata.

Even assuming Mr. Osterberg's figures as to the cost of plants for the two systems to be correct, we think that he has taken too rosy a view of the cost of maintenance of the block stations to admit of a valid conclusion being drawn as to the relative economy of the two systems of operations. If, as he assumes, the underground system would cost $500,000, making an annual interest of $30,000 per year, and a cost to each of the five thousand buildings of $6 per year for the underground distribution, we are not quite so sure but that the janitors' fees in the case of the block system would not equal a like amount, that is, fifty cents a month. He has also left out of consideration the fact that the item of fire insurance in these plants would make a not inconsiderable item. They would certainly be classed as central stations and would be charged for as such. Indeed, it seems highly probable that decided restrictions would be placed by the insurance authorities on the operation of such plants, liable to so much individual carelessness, and that the insurance on contiguous property would be also affected unfavorably. Mr. Osterberg also assumes apparently that every one of the buildings in each block would take current, which past experience shows to be a very dubious condition.

As to the efficiency of isolated plants under which the block stations would have to be classed, there is still a deplorable lack of reliable information. We doubt if the owner of a single building operating an isolated plant is able to tell exactly what his lighting is costing him. Most of these buildings have steam plants for operating the lighting plants, as well as elevators, while in winter they are drawn upon for the heating of the building, and the difficulty of separating the costs of these various items is evidently very great. But if we read the signs of the times aright the owners of buildings are beginning to awaken to the fact that the supposed economy of their isolated plants is not always so great as they have assumed, and we know of more than one instance where large office buildings have been connected to the street mains.

Nevertheless there seems to be a tendency towards the installation of block lighting plants, and it would be well for central station managers to watch the progress in this direction closely. We do not by any means believe the central station is doomed. Mr. Osterberg's figures do not show any advantage of the block system over the central station system, even when the cost of distribution is included in the latter, while as to the cost of operation his own figures show that he has neglected a number of most important items. Besides he has assumed the distribution for the central station at low pressure. In this he has taken the most unfavorable conditions, as far as cost of feeders is concerned. As regards this point there is no reason why the central station of the future should handicap itself in such a way. Indeed, there is no good reason why the up-to-date central station should not distribute current in the same way as by the block system method. This would involve the construction of the central station at the water side, current generated by means of gas engines, driven by gas produced on the premises, distributed at high voltage to sub-stations in each block, or group of blocks, and there converted either by static or direct current transformers, with or without storage batteries. The system here outlined can hardly be termed one of the future, as it has, so far as the method of distribution is concerned, already gone into practical operation in several cases, a notable instance being the city of Budapest, where it has been found to be decidedly economical. We need only cite one more apparent oversight of Mr. Osterberg's, and that is the failure to allow for possible breakdowns. No central station could afford to deprive its customers of current for even a few minutes at a time, and maintain its business. This requires an installation of apparatus sufficient to tide over any trouble in any of the power or generating units. This means duplication of apparatus. In the case of a block system it would mean duplication of all power and electrical units, and would entail an expense not contemplated in Mr. Osterberg's figures. Taking all this into consideration we have no fear for the future of the central station, and the improvements which will be brought about will gradually lower the cost of current to a point, at which isolated plants will scarcely be thought of as a proper investment, within areas supplied by good central stations, unless other conditions come in to justify their installation.

CHRISTMAS STORE ELECTRICAL EFFECTS AND DECORATIONS.

We shall be glad to receive from any of our readers in central stations or isolated plants an account of work done specially for the illumination or decoration of stores and store windows at the holiday season. We are in receipt of inquiry on the subject, and it seems to us that an interchange of ideas and experience in this direction would be useful to all. If any photographs or diagrams of such work can be forwarded to us, it will be helpful.

Electric Transportation.

THE ENGLEWOOD AND CHICAGO STORAGE BATTERY RAILWAY.

NUMEROUS attempts have been made to operate street railways in the United States by means of storage batteries, but for one reason or another success has not attended the experiments. The reasons for the failures of the past may

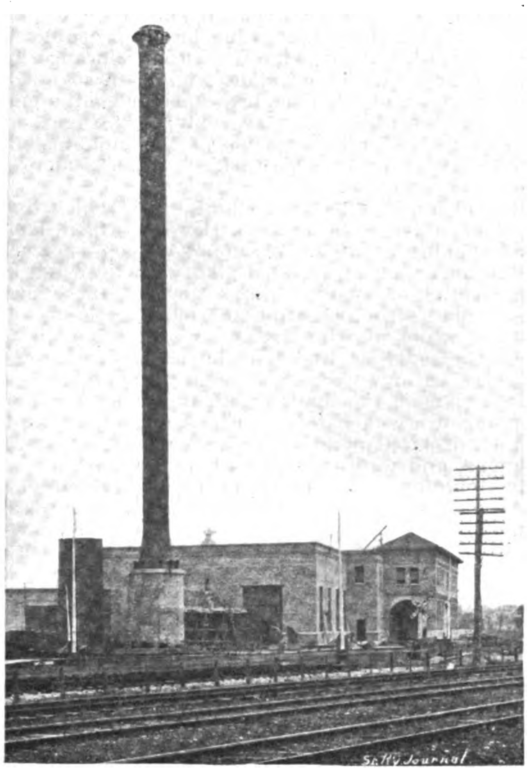

FIG. 1.—ENGLEWOOD AND CHICAGO POWER HOUSE.

not be far to seek, but enough experience has been gained to point the way how not to do it. It is, therefore, with no little interest that street railway men will watch the progress of the Chicago and Englewood road, which went into preliminary operation a few weeks ago.

THE ROUTE OF THE ROAD.

The route of the road is intended to be ultimately between Sixty-third street and the town of Harvey. At present, however, tracks are laid only to Blue Island, and this completed portion of the road will be first put in regular operation. The two cars now running travel from the power house at South Englewood to the northern terminus of the line.

The road begins at Sixty-third and Vernon avenue, right beside the Alley Elevated road's tracks. In order to land passengers at a station of the latter transportation line, the street car company has bought up a right of way through the block from Vernon to South Park avenue and will ultimately stop its cars along the sidewalk just at the foot of the stairway leading up to the elevated structure. As the Calumet Street Railroad Company also uses this point for a terminus, it is getting to be one of the centers of Woodlawn Park.

From Sixty-third street the route of the new road is straight south to South Chicago avenue, with a run of half a block on Sixty-seventh street. On South Chicago avenue the battery cars fall in line with the trolley motors of the Calumet system, which leaves the Englewood and Chicago's tracks at this point for a few blocks. When Seventy-first street is met, however, the route turns sharply to the west and runs toward Auburn Park as far as State street, where it is within a couple of blocks of the Chicago City Railway's trolley lines.

From Seventy-first and State streets the tracks run due South along the newly paved thoroughfare which promises in time at this end to maintain the reputation for business it holds in the downtown district. At Seventy-ninth street another turn is made to the west, until the Vincennes Road is reached at the southernmost point of the City railway's system. Except for a small twist to the west on Eighty-first street, where both the Chicago and Western Indiana and the Chicago, Rock Island and Pacific tracks are crossed, the general course of the line is then to the southwest along the Vincennes road to Western avenue in Blue Island. Then the latter street is followed south to the present terminus at the railroad crossing in the heart of the town.

A spur line, to act as a feeder, runs from the junction of the Vincennes road and Morgan avenue west on the latter street through Morgan Park. It ends at Mount Hope Cemetery after skirting the edges of Mount Greenwood and Mount Olivet Cemeteries. Other feeders are projected to connect with various points in Englewood, Pullman, Kensington, Roseland and Auburn Park. At present over twenty-one miles of track are laid, of which nine miles are double track and three single track.

TRACK CONSTRUCTION.

The road is equipped with eighty-pound Johnson seven-inch girder rails. These rest on eight-foot ties provided with tie-plates, laid every two feet along the route. The whole is put on a foundation of six inches of slag or crushed stone, and this was not laid until the street had been settled by a steam roller. Six-bolt fishplates are used at the joints, and tie rods every thirty-three feet. Altogether the track, with its absence of bonding wires and heavy construction, appears more as if designed for steam traffic than an electric street car line.

Along the route of the new line carriage roads have been made for the residents. A large portion of the way is though swamps and over prairie ground, where the only thoroughfares were cleared spaces in the mud. They have now developed into well-paved streets at the expense of the street railroad company, which, it is estimated, has spent in the neighborhood of $25,000 for carriage road building alone.

THE POWER HOUSE AND CAR BARN.

The power house and car barn shown in their present condition on this page, Fig. 1, are located at Eighty-sixth street and Vincennes Road, just beside the curve of the Rock Island Railroad's suburban line at South Englewood.

The building, as at present standing, is 175 feet long by 102 feet wide, and beside the power arrangements will hold twenty-eight cars in shelter. When at its full size it will be 258 feet long by 102 feet wide and will hold comfortably the fifty cars ultimately intended to be in service. These are to be stored on tracks in the car barn part, and will be put there by a large electric transfer table running the entire length of the building and connecting the outside tracks with those in the interior of the building.

The new offices at the power house, which are situated over the front porch, will be ready for occupation in less than a

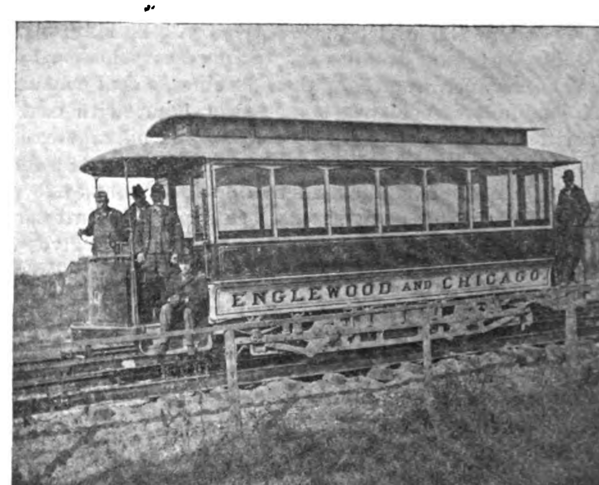

FIG. 2.—ENGLEWOOD & CHICAGO STORAGE BATTERY CAR.

month's time. They will comprise a private and large general office, and on the same floor will be a reading room for conductors and motor men, a room with lockers, shower baths and toilet rooms, and also a waiting room.

THE BATTERY-CHANGING ARRANGEMENTS.

The tracks leading from the street into the car barn are so arranged that the cars may be brought into the building from

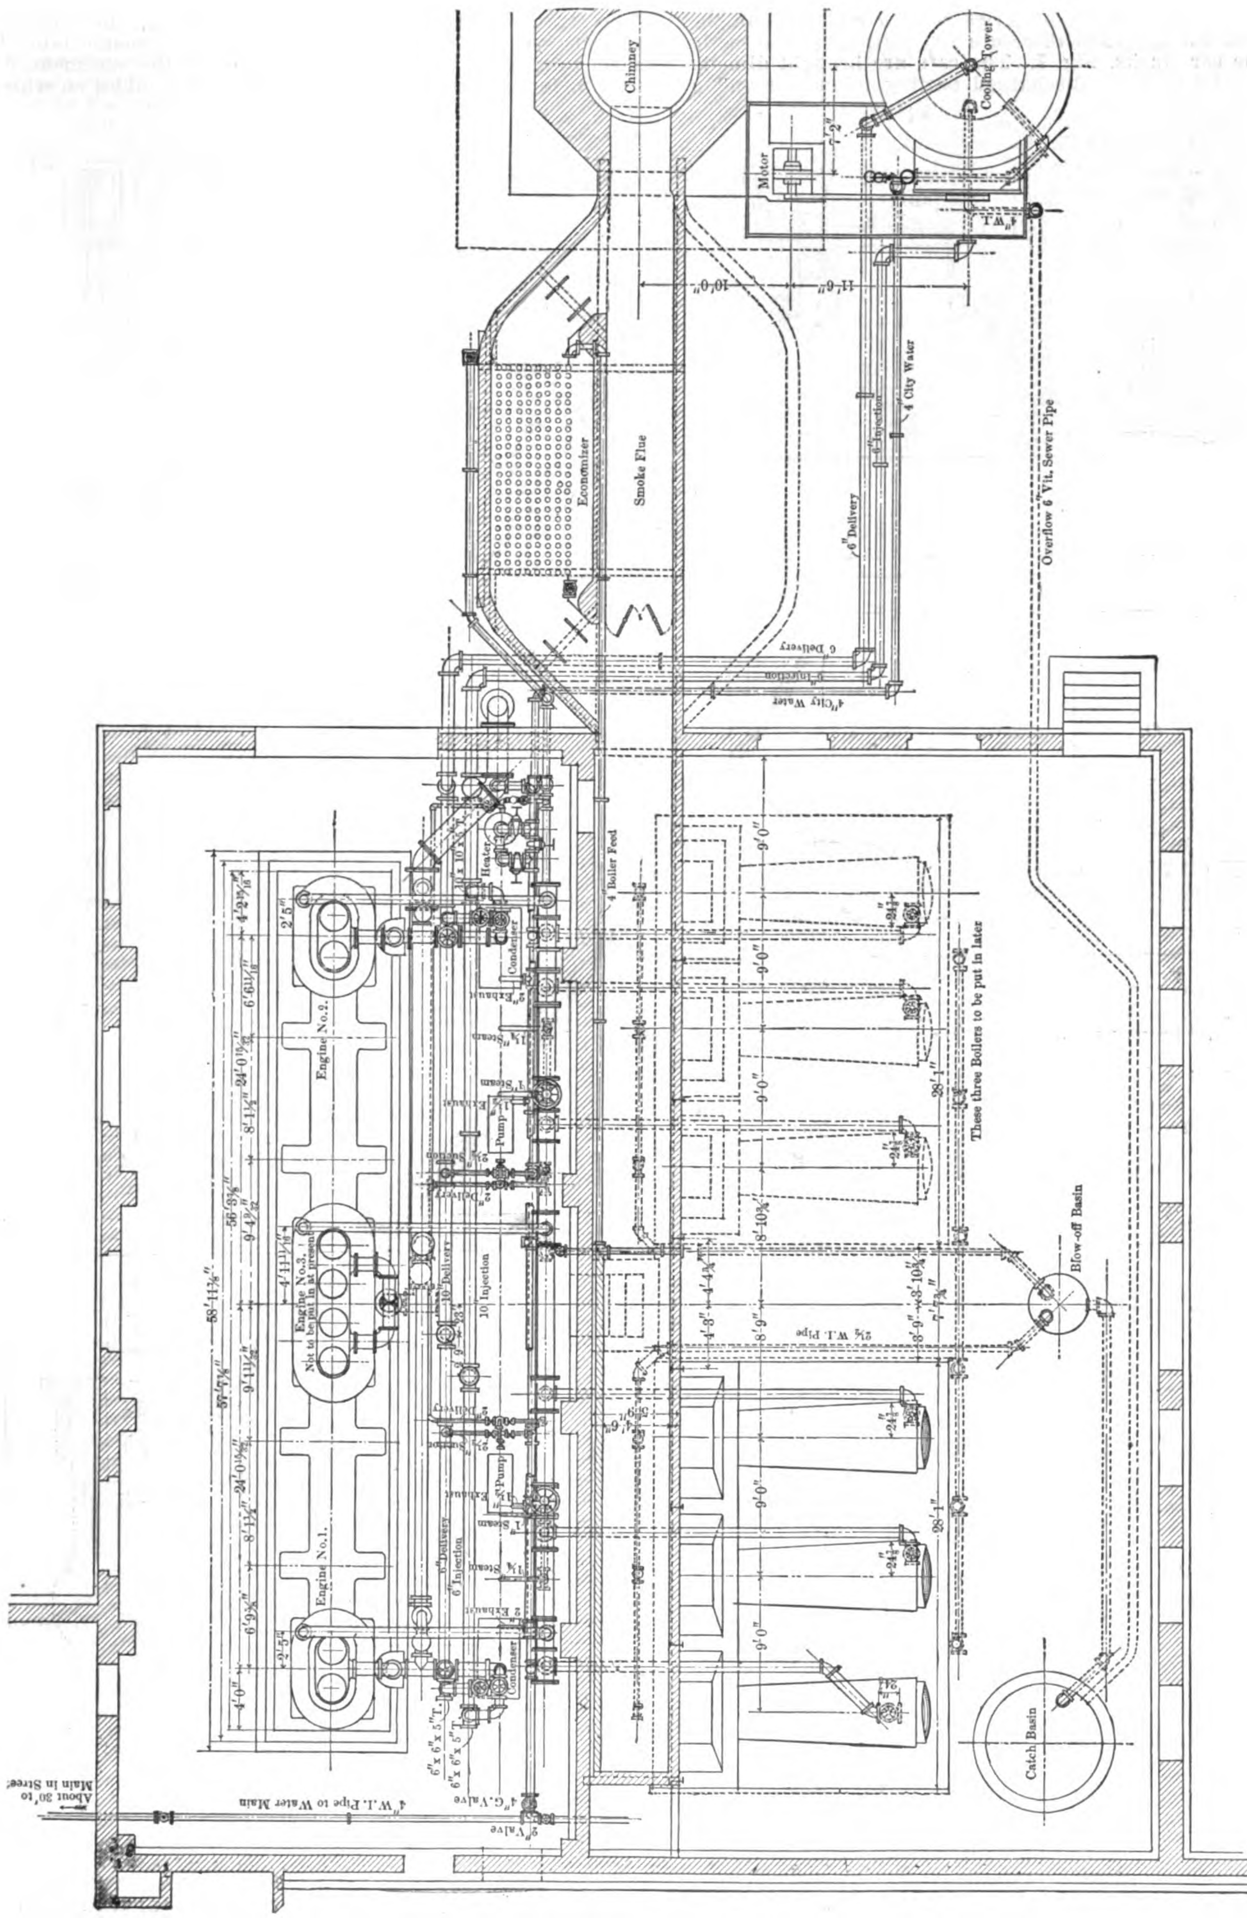

Fig. 7.—Power Plant, Englewood & Chicago Electric Street Railway Co.

either direction, so that the batteries may be replaced. In the front part of the car barn there are two battery pits directly beneath the car tracks, Fig. 7. The cars are brought directly over these pits and the discharged battery taken out and a charged battery put in its place. This operation will require not more than two minutes, so that the delay is not serious.

The batteries are handled by a battery transfer elevator shown in Fig. 3. This device consists of a car operated by **an electric motor and having on each end a platform provided with rollers on which the battery tray is placed when being moved or raised into position under the cars. There are two of these elevators in the car barn, one at each side.**

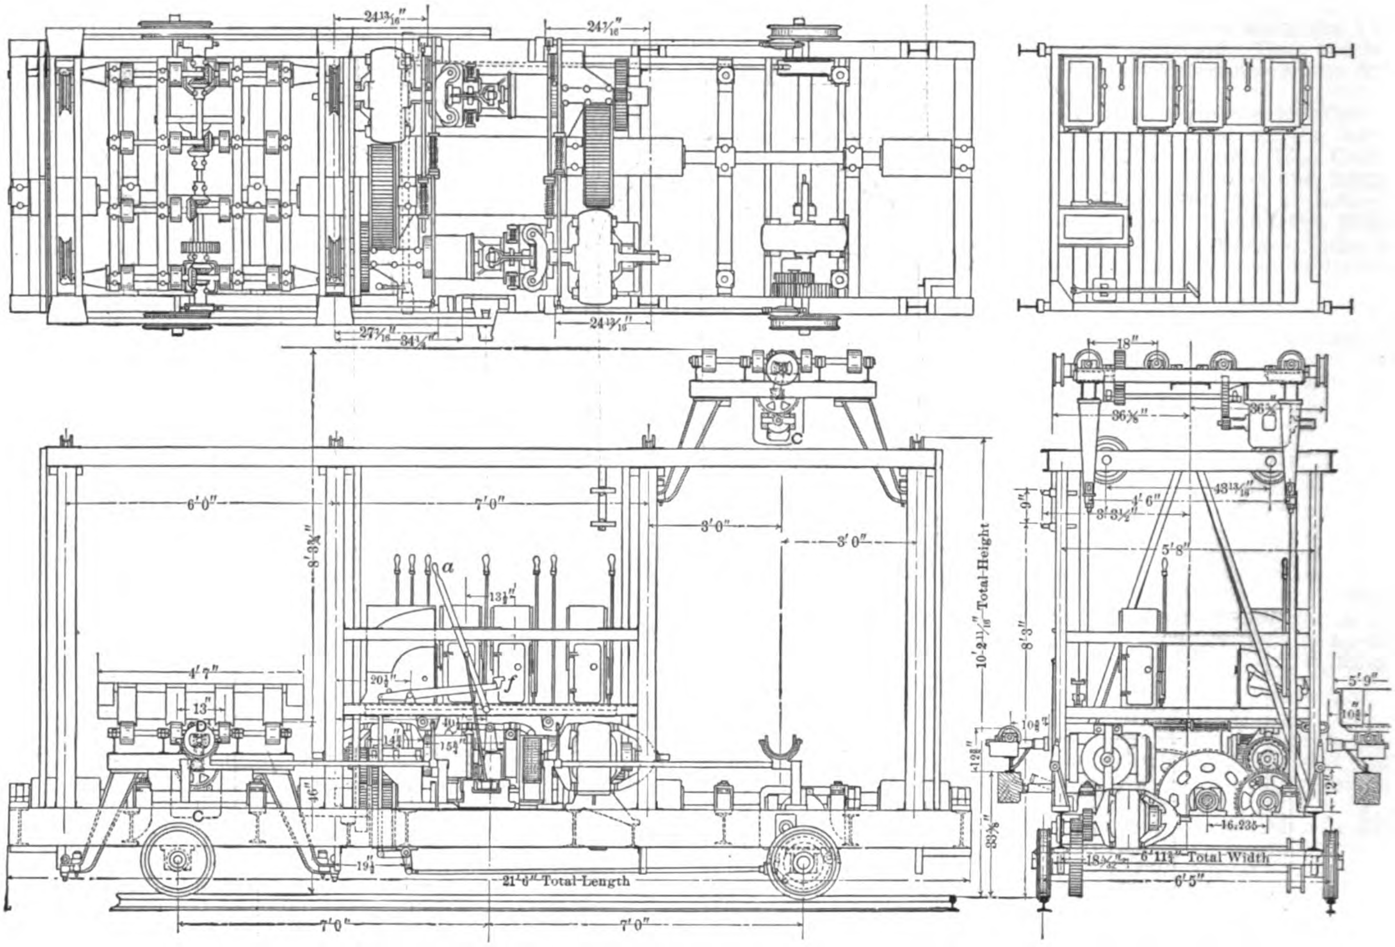

FIG. 3.—BATTERY ELEVATING AND TRANSFER TABLE, ENGLEWOOD & CHICAGO ELECTRIC STREET RAILWAY CO.

The arrangement of the battery room in which the trays are charged, is also shown in Fig. 8. The battery transfer table is shown running on rails in the lowest part of the basement, directly under the cars. The frames or charging tables on which the batteries are placed for charging, are at either side of this transfer pit. These charging tables are provided with rollers similar to those on the transfer elevator and a clutch coupling is arranged so that the rolls on the elevator may be coupled **to the rolls on the charging tables. These rolls are operated by electric motors controlled by the operator who stands in the center of the battery transfer table. The battery trays are raised and lowered by means of electric hoists at each end of**

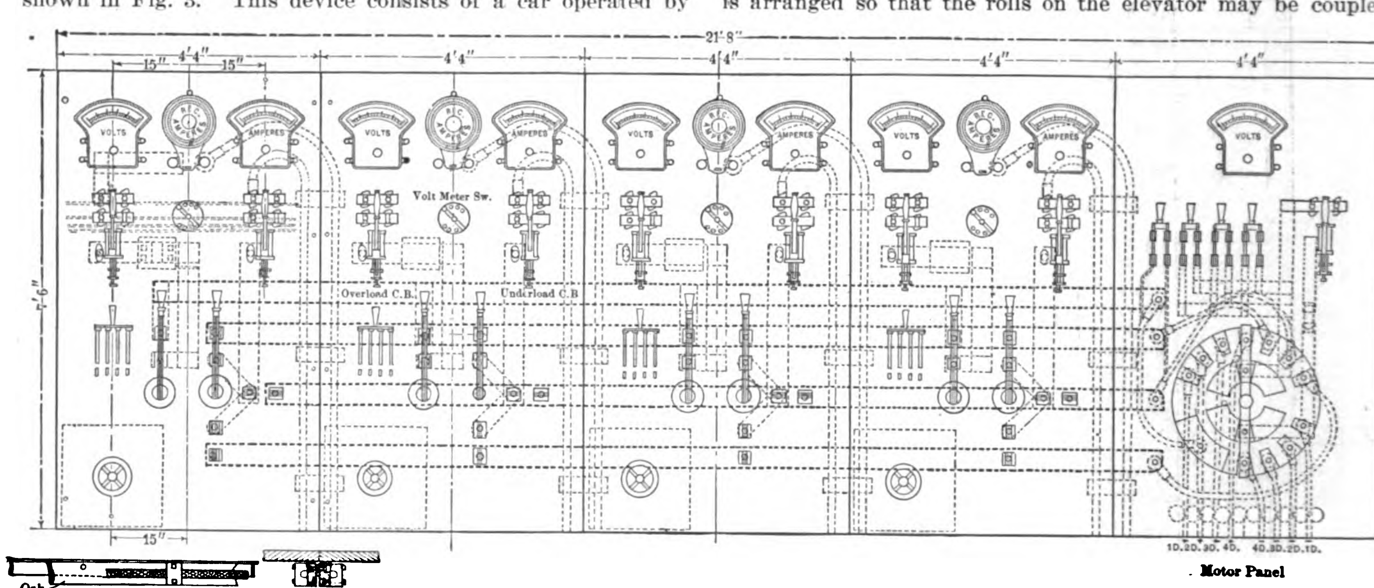

FIG. 4.—BATTERY SWITCHBOARD, ENGLEWOOD & CHICAGO ELECTRIC STREET RAILWAY CO.

the battery transfer car. In the engraving the platform carrying the battery is shown at its lowest position on one end, and raised to the highest possible position on the other end. There are five motors in all on the transfer car, all operated by one attendant. This battery transfer car has been furnished by the Shaw Electric Crane Company, of Muskegon, Mich. It is one of the most important features of the plant, for on its successful operation depends in a great measure the success of the system. At night all the cars are taken into the car barn by means of the car transfer table and run into their respective tracks above the battery pit where the batteries can be replaced so that the cars will be ready for service the next day.

THE POWER PLANT AND METHOD OF CHARGING.

In charging the batteries three voltages will be used, the aim being to charge the batteries at nearly a constant rate during the entire period of charge. The discharged cells will be connected, first, to the low pressure omnibus bar, and then as their electromotive force rises they will be connected successively to the next two higher voltages. In this manner the batteries are to be charged in the most economical way without the loss of energy in resistances or in counter electro-motive force cells. It is the intention to operate three generators of different voltages all the time. Figs. 5, 6 and 7 show the arrangement that has been adopted for

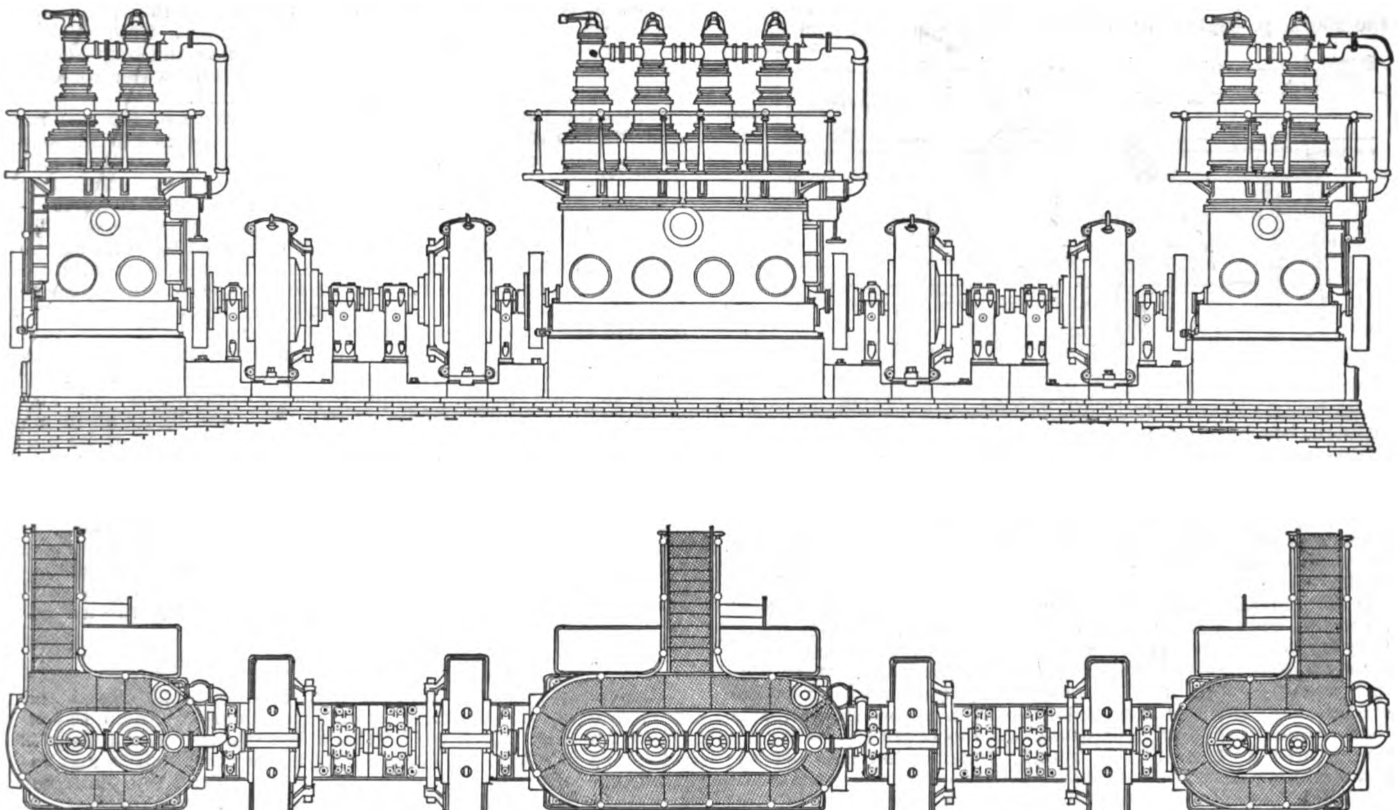

Fig. 5.—Engine and Dynamo Arrangement, Arnold System, Englewood & Chicago Electric Street Railway Co.

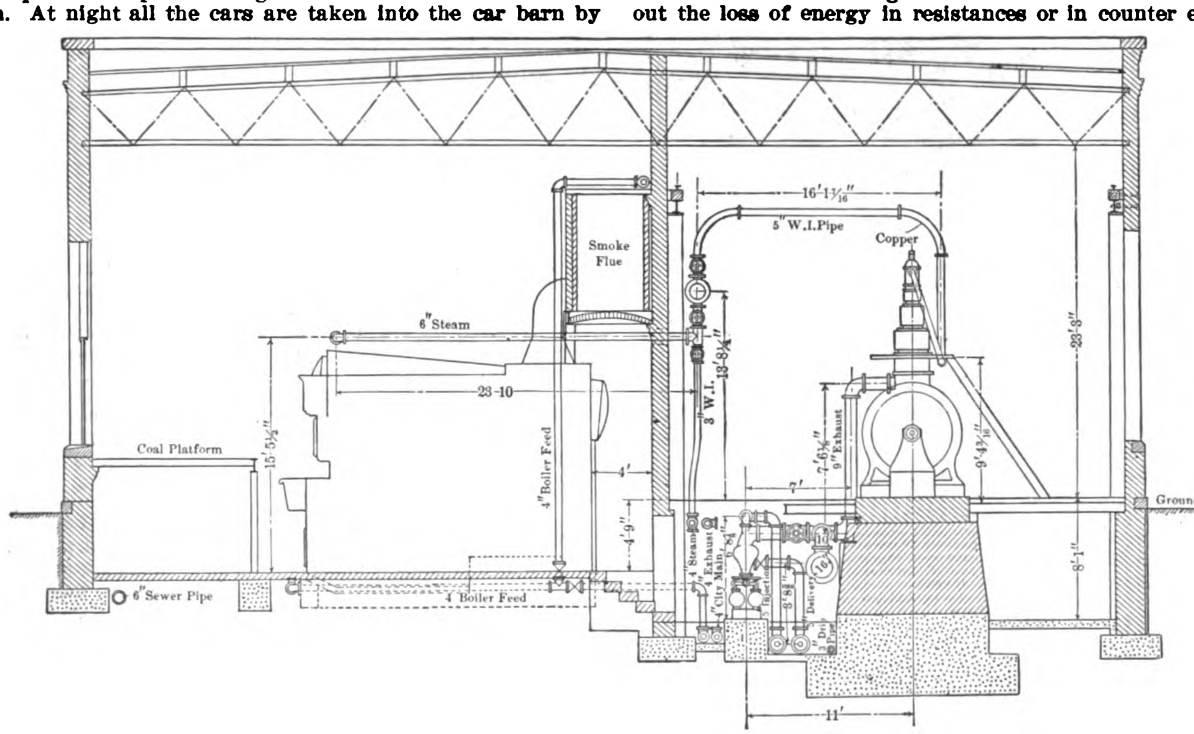

Fig. 6.—Elevation of Piping for Power House, Englewood & Chicago Street Railway Co.

the engines and dynamos. The plant consists of four 250 k. w. Walker generators and three Willans triple expansion engines running at 380 r. p. m. These units are connected according to the "Arnold system," so that it is possible to operate any one or all four of the generators from the large 500 h. p. engine in the middle, which will be installed later, while either of the 250 h. p. engines at the ends of the shaft can run either,

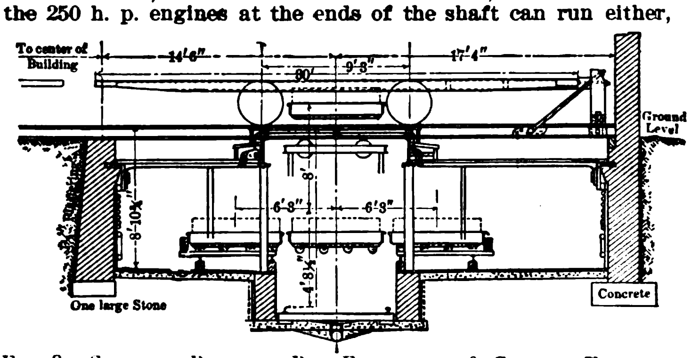

Fig. 8.—Storage Battery Pit, Englewood & Chicago Electric Railway Co.

or both, of the adjacent generators. The conditions call for the operation of three generators most of the time, and it will be seen that by this arrangement it is possible to run three direct conected generators with one engine, while at the same time ample capacity of both engines and generators is held in reserve in case of a breakdown. The entire plant of 1,000 h. p. of engines and generators occupies a space only 55 feet long by 12 feet wide.

It is evident that by the adoption of the "Arnold system" there has been secured a power plant of less first cost and occupying much less floor space than one designed along the usual lines of independent direct connected units. In the latter case to secure the same reliability and capacity of the present arrangement it would have been necessary to install four engines and four generators. In the operation of such a plant three units would be runnig underloaded most of the time, while with the plant shown it is the intention to operate the 500 h. p. engine in the middle at its full capacity and thus at its maximum efficiency. As the dynamos generate directly three different voltages, no boosters will be required in the plant.

The complete boiler equipment consists of six 200 h. p. Heine boilers, of which three are put in at present. These boilers are equipped with the Roney stoker. An iron platform is built directly in front of the boilers at such a height that the coal may be shoveled into the hoppers of the stokers without raising it. The coal is shoveled directly onto this coal platform from the cars on the side track outside the building.

A Greene fuel economizer, consisting of 192 pipes, is provided in the smoke flue to heat the feed water before it enters the boilers. A steel self-supporting smokestack, 150 feet high, is furnished by the Variety Iron Works, of Cleveland. This stack sets on a brick base about 22 feet from the ground, the smoke flue entering this brick base.

The Green economizer acts, as it were, as a storage battery for the boiler plant. There is always the large reserve of water above the evaporated point in the economizer ready for use in the boilers, and by means of this reserve the firemen are able to keep the steam constant and work the boilers at their greatest efficiency. The economizer, for this reason, makes a considerable saving above the actual saving that is due to raising the temperature of the feed-water.

The engines will be run condensing and all condensers and boiler feed pumps have been furnished by the Worthington Company. A cooling tower has also been erected by the same company for cooling the water after leaving the condensers. The water from the condensers is pumped to the top of the tower, where it is formed into a spray, and drops through a series of sewer pipes placed on end in the tower. Through these sewer pipes a draught of air is forced by means of a blower in the base of the cooling tower. The evaporation of the water is sufficient to cool its temperature, so that it may be used over and over again in the condensers. This cooling tower was used, as the city water main was the only source of water supply, and the expense of using city water for condensing purposes would otherwise be too great.

While the batteries are being charged, three of the generators will run continuously; one at 150 volts, one at 170 and one at 190. The batteries will be first run on the 190 volt circuit, the batteries being connected successively to the other two voltages. The mains in the car barn are run on a compensating system, so that the voltage at any battery is the same in any part of the building. This is accomplished by running the positive mains clear around the building in one direction, while the negative mains are run the same distance in the opposite direction. The current to any battery, therefore, is obliged to traverse the entire circuit of the building.

An ingenious device has been designed to indicate to the attendant in the battery room when the batteries are fully charged. This piece of apparatus is practically an ammeter, with a device which makes contact and lights an incandescent lamp when the current has dropped to 25 or 30 amperes. The operation of this instrument is as follows: When the batteries are first put on the charging circuit, their e. m. f. is low and the amount of current which they will take is correspondingly large. As the voltage of the battery rises, the amount of current which may be run through it is decreased until the voltage has become sufficiently high. The instrument is adjusted so that a contact is made at this point and an incandescent lamp is lighted up, thus warning the attendant that the battery is charged.

THE CAR TRUCK AND BATTERY EQUIPMENT.

The car equipment will consist ultimately of 20 closed and 20 open cars built by the St. Louis Car Company, mounted on Dupont trucks. Each car carries a battery tray containing 72 cells, 8 by 5 inches, by 18 inches high, weighing 4 tons and capable of delivering 400 amperes at 150 volts. The batteries are furnished by the Electric Storage Battery Company, of Philadelphia, and are designed especially for traction use. The two cars now running with these batteries have been in use for a little over a year in New York City, and the batteries are still in good repair. These cars are at present in regular service on the line of the road, having been brought on from New York. The Dupont truck is shown in Fig. 9.

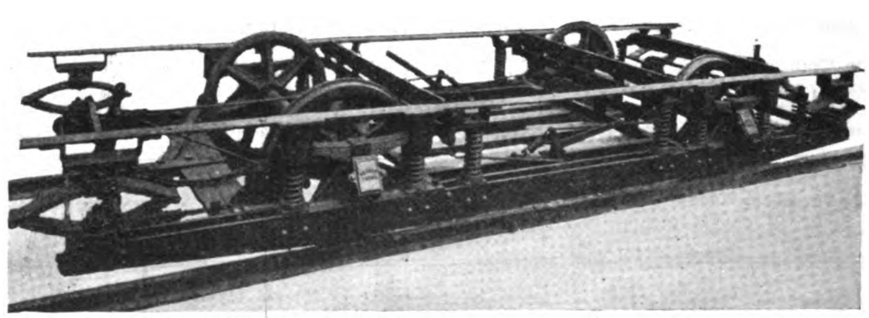

Fig. 9.—Dupont Car Truck, Englewood & Chicago Electric Street Railway Co.

Contact plates are fastened on the sides of the battery tray, so that when it is raised in position on the car, connection to the controller wiring is immediately made. A detail of the spring contact on the car, is shown in Fig. 10. Similar contact devices are provided at the sides of the charging tables in the battery room, so that as soon as a battery tray is put in position, it is ready for charging without further trouble.

The battery tray is supported on the cross-bars between the wheels of the truck. There are four 5-inch channels under this battery tray which serve to support it, these channels being bent up at the ends and formed into hooks. Fig. 9 shows the truck with these channels in position, hanging from the cross-bars. There will be one 50 h. p. Walker motor on each truck. The latter is provided with both a handbrake and friction brake, the latter being composed of two discs; one of each is keyed fast to the axle, the other being forced against it by the motorman when it is desired to stop the car. This winds up a chain, thus applying the brakes. Owing to the extra weight of these cars, this increased brake power was thought necessary.

THE MANAGEMENT.

Mr. G. Herbert Condict, the general manager, upon whom

the heaviest part of the work of the construction of the road devolved, made great and most creditable progress during the spring and summer months of this year, and had frequent consultations with Mr. B. J. Arnold, Chicago, who is consulting engineer to the company, and also with Mr. J. H. Vail, of Philadelphia. Mr. Condict has also received very able assistance from Mr. Hugh Hazleton, a young and energetic engineer who makes his headquarters at the power house.

When completed this plant will be one of the most up-to-date

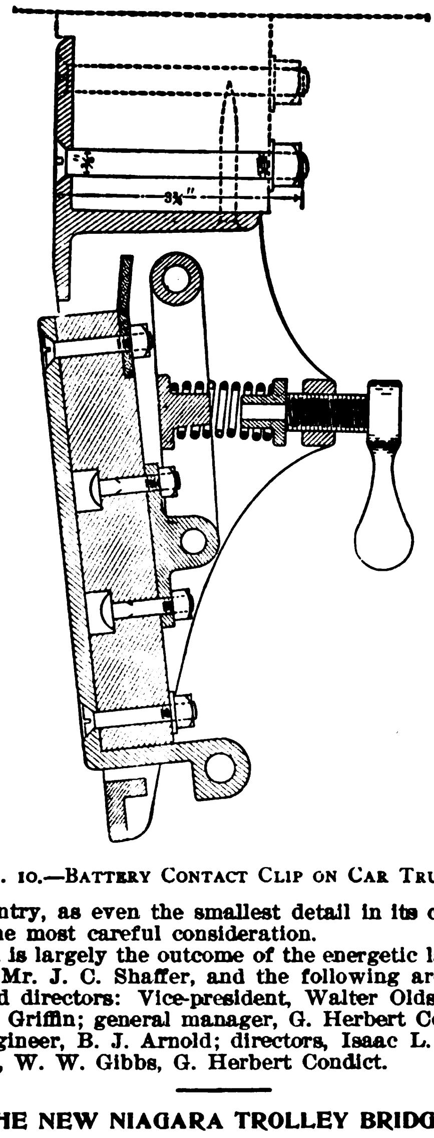

FIG. 10.—BATTERY CONTACT CLIP ON CAR TRUCK.

in the country, as even the smallest detail in its construction has had the most careful consideration.

The road is largely the outcome of the energetic labors of its president, Mr. J. C. Shaffer, and the following are the other officers and directors: Vice-president, Walter Olds; secretary, Charles F. Griffin; general manager, G. Herbert Condict; consulting engineer, B. J. Arnold; directors, Isaac L. Rice, Herbert Lloyd, W. W. Gibbs, G. Herbert Condict.

THE NEW NIAGARA TROLLEY BRIDGE.

BY ORRIN E. DUNLAP.

IT is highly probable that the first trolley car to enter the Dominion of Canada from the United States on its own track and by its own power will cross the Niagara gorge when the fine new steel arch bridge, now in course of construction, is completed. This bridge will be one of the finest structures of its kind in the world, and the work of erecting it is attracting much attention in engineering fields. Mr. L. L. Buck, M. Am. Soc. C. E., is chief engineer in charge of the work, and the Pennsylvania Steel Company has the contract for the superstructure. The new arch will replace the railway suspension bridge over which the Grand Trunk, Lehigh Valley and Erie trains run. The lease, however, is held by the Grand Trunk, and the new bridge will greatly increase this company's facilities in crossing the Niagara chasm.

The arch will have a span of 550 feet between the end piers, and it will be connected to the top of the bluff by a trussed span 115 feet in length. The main span will be formed by an arch with horizontal upper chords.

The bridge will have two floors or decks. The upper floor will be devoted to steam railway purposes, and will contain two tracks. The lower floor will have walks for pedestrians, carriage ways and trolley tracks.

The load the bridge is expected to carry is enormous. It is designed to carry on each railroad track a load of two locomotives, with four pairs of drivers each and 40,000 pounds on each pair, followed by a train of 3,500 pounds per foot. This would make 7,000 pounds live load on the upper floor, but in addition to this the bridge is designed to carry a live load of 3,000 pounds per running foot on the lower floor, making no less than 10,000 pounds live load in all. This, as intimated, forms an unusually heavy load for a bridge.

It will surprise many to learn that while the new arch is being built the old railway suspension bridge will remain in daily use, and is not expected to in the least interfere with the labors of the construction gangs. To build a bridge of the size proposed arch is a task of no small magnitude, but to put it right on the site of a bridge of different design increases the task in no small degree. But this is just what is being done at Niagara, and the way it is done is that the end spans and first panels of the arch will be built on the scaffolding in place. Then the end spans will be connected with the end post of the arch, and by the approach girders, with the temporary anchorage, when the two parts of the arch will be built out by cantilevers. The upper floor beams of the arch will be left out until the old structure can be raised high enough to allow the new beams to be inserted under the upper chords of the old bridge. While this is going on the suspension bridge will rest on the lower floor beams of the new arch, and therefore the towers and cables of the suspension bridge can be removed. When this point of progress is reached the suspended structure will have to be shoved far enough to one side to allow the laying of one track on one pair of the new stringers, and after the old bridge has been wholly removed the second track can be placed and the work hurried to completion. As a franchise for the erection of a new bridge at Lewiston has been granted by the Legislature, it is proposed to remove the old suspension bridge to that point and there re-erect it.

BOSTON WEST END FIGURES.

The West End (Boston) Street Railway Company reports for the year ended September 30, 1896: Gross earnings, $8,341,958; ditto 1895, $7,746,170. Increase, $595,788. Operating expenses, $6,334,619; ditto 1895, $5,633,163. Increase, $701,456. Net earnings, $2,007,339; ditto 1895, $2,113,007. Decrease, $105,668. Fixed charges, $794,601; ditto 1895, $746,964. Increase, $47,637. Balance, $1,212,739; ditto 1895, $1,366,044. Dividends, $1,147,950; ditto 1895, $1,102,525. Increase, $45,425. Surplus, $64,789; ditto 1895, $263,519. Decrease, $198,730. The car mileage run for the year ending September 30, 1896, has been 25,841,907 miles, an increase of 3,661,782 miles. The number of revenue passengers carried has been 166,862,288, an increase over the preceding year of 11,630,782. The number of employés in all departments is 4,750.

LONG ISLAND R. R. ADOPTS ELECTRIC LOCOMOTIVES.

President Baldwin and other officials of the Long Island Railroad have been considering for months the feasibility of electricity as a motive power, and are convinced that old-fashioned locomotives can now be supplanted by electric motors. It is not intended to use the motors to run to distant points of the island, but to nearby places, such as Jamaica, Flushing, Mineola, Far Rockaway, College Point and Manhattan Beach.

President Baldwin says: "There is no doubt that the motors have arrived at such a stage of perfection that they can be used with benefit to our patrons and the road. We will go slow in the matter, because simplifying improvements are being made every day, and we want the best in the market. I think some of the motors will be in operation next summer."

UNDERGROUND ELECTRIC RAILROADING IN LONDON.

A meeting of the Metropolitan District Railway Stockholders' Association was held on Nov. 20, in furtherance of the project for constructing two deep level tunnels for an up and down service of express electric trains between Earl's Court and the Mansion House. The stockholders have indorsed the action of their directors in approving the scheme, and the necessary powers will be asked for at the coming session of Parliament. That they will be granted is a foregone conclusion. Parliament has already sanctioned six metropolitan underground projects, and two will be sanctioned at the forthcoming session. There are still others in the air, all electrical. Most of these lines are planned to rectify the extraordinary want of foresight which practically forbade the termini of the great

railways to advance beyond what were, in the days of their building, the suburbs of London. The result has ever since been that the traveler consumes as much time in getting from one great terminus to another on the other side of the metropolis as would suffice to carry him fifty miles on his journey.

TELEPHONY AND TELEGRAPHY.

CAILHO'S SYSTEM OF SIMULTANEOUS TELEGRAPHY AND TELEPHONY.

IT was M. Van Rysselberghe who first pointed out a feasible method of utilizing telephone lines for the transmission of telegraphic signals during transmission of telephonic messages. This he accomplished by an arrangement of apparatus by which the telegraphic signals are graduated as to the rise and fall of current strength, so that while still able to actuate the telegraphic apparatus they are powerless to influence the telephone diaphragm. There were, however, certain inherent faults in the Van Rysselberghe system which it has been the aim of several subsequent inventors to overcome, and among them we may mention Maiche, Picard, Jacob, and latterly M. Cailho, who, according to the "Journal Telegraphique," has solved the problem in a most elegant manner.

M. Cailho, while taking as the basis of his system the use of the metallic circuit for the telephonic transmission and the system of two wires connected in parallel for the telegraphic, like Maiche and Picard have done in the past, first employed the Van Rysselberghe graduators, inserted in each of the wires; but he very soon replaced this device, disturbing to rapid telegraph signal transmission, by a simple coil with two circuits.

The arrangement of M. Cailho is shown in Fig. 1. The coil consists of two windings, a and b, of two exactly identical wires, carefully insulated one from the other, and wound simultaneously on the same core, consisting of a bundle of annealed and paraffined iron wires. The telegraphic impulses divide at the point, v, into two equal parts and traverse the two windings in opposite directions with respect to the axis of the solenoid. Consequently the effect of self-induction will be almost nil. The case is different, however, for telephonic currents. It will be seen that in the latter case the telephonic currents which tend to pass into the coil would traverse the two windings in the same direction. The bobbin would then act as a coil of high self-induction with respect to these currents, so that the latter are transmitted almost with their full strength on the line. It results from this that the telephonic currents are stopped by the coil, which, on the other hand, does not in any way interfere with the telegraphic signals.

In order to avoid the effects of the extra current of rupture

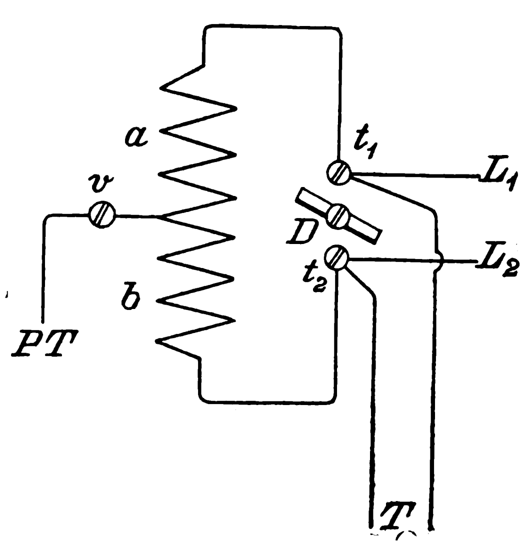

FIG. 1.

at the end of each telegraphic signal, which may in certain cases prove disturbing, M. Cailho had already, in 1890, suggested the use, and sometimes the necessity, of putting a condenser in shunt to the telegraph transmitter PT, the object being to prevent the click in the telephone which is heard the moment when the point, v, is insulated from the battery by the action of the telegraph key. However, this action only manifests itself with a coil in which the resistance is considerable, as related to the self-induction, but without seriously interfering with conversation. As a matter of fact, M. Cailho states that not a single telephonic circuit leaving Paris has any condenser in shunt. This is a great advantage, as con-

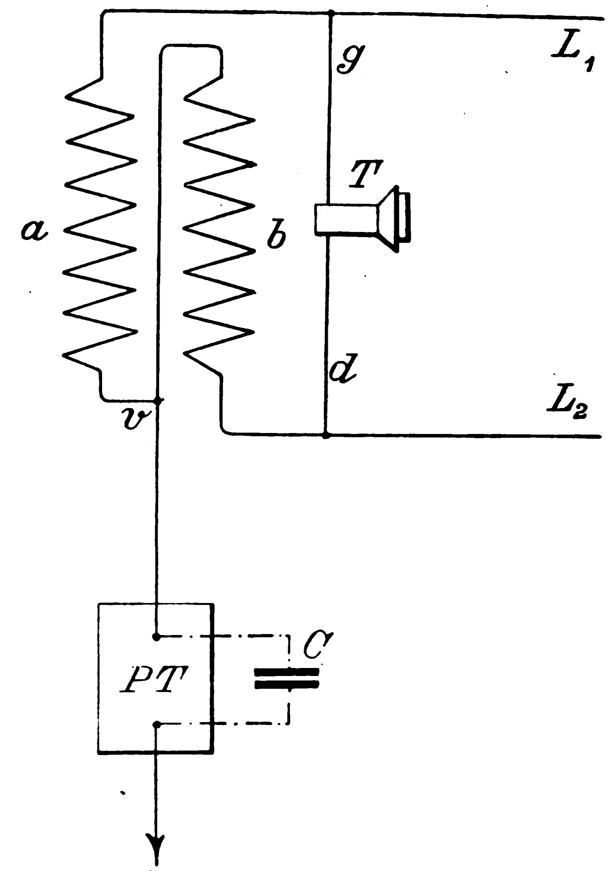

FIG. 2.

densers necessarily have to be provided with very sensitive lightning arresters, which were the principal bugbear in the Van Rysselberghe system.

The latest coils used by M. Cailho, made by L. Digeon & Co., of Paris, have 300 ohms resistance, and 6,800 turns for each wire. The latter of German silver has a diameter of 0.22 mm. For this model of coil M. Cailho has separated the two windings, winding one on each half of the core. By this arrangement the two telephonic circuits do not absolutely annul each other, but in practice for lines of small importance this method of construction is adequate, and much simpler than the one cited above. The following electrical and magnetic details of the coil are given:

SELF-INDUCTION.

Winding a (b, insulated).................	4.92	Henry
Winding b, (a, insulated)	4.91	"
a + b	14.60	"

RESISTANCE.

Winding a (b, insulated)..................	299.92	ohms
Winding b, (a, insulated)	299.93	"
a + b	599.85	"

The coil, not including the end piece, is 7 cms. long and 4 cms. thick for each winding. The core is 3 cms. in diameter. The apparatus is mounted on a base and protected by a box. In Fig. 2, t_1 and t_2, are the terminals connected to the telephonic apparatus, and those to the line, L_1 and L_2. M. Cailho has also experimented with coils having between 5 and 20 ohms, and even with some as low as 1 ohm, in order to show the possibility of telephoning even with very small resistance in shunt to the circuit, provided the self-induction of the shunts is very high. We may add, for the benefit of those of our readers who may want to try the Cailho system without making special coils, that they can, if need be, be replaced by Morse relay magnets having a resistance of five or six hundred ohms. The wire coming from the telegraph end, PT.

Fig. 2, is then connected to the junction of the two coils of the magnet.

The Cailho system is now in quite extensive use in France; thus it is employed on two circuits between Paris and London, and the lines connecting Paris with Nancy, Lavallois-Perret, Santes (Bordeaux), Limoges, Chartres, Vichy, as well as on other lines radiating from Rouen, Marseilles, Lille, Dijon, Cette, etc.

POWER TRANSMISSION.

VOLTS VS. OHMS.—SPEED REGULATION OF ELECTRIC MOTORS.[1]

BY H. WARD LEONARD.

THE object of this paper is to endeavor to show the advantages arising from the use of a system of motor control having several modifications, but all of which involve the idea of controlling the speed of an electric motor by controlling the e. m. f. generated in its armature circuit and without using any regulating resistances in that circuit.

Fig. 1 shows the first and simplest form of the e. m. f. system of motor speed control. S is an engine or other source of power operating at a practically constant speed. G is a generator. M is the motor. E is a circuit of constant e. m. f. which supplies current for exciting the fields of G and M.

It will be noticed that the fields of both G and M are independent of the e. m. f. and current of their armatures. The field of M is practically constant. The field of G is variable from full strength to zero strength by manipulation of the controlling rheostat C in the field circuit of G. It will also be noticed that there is no rheostat in either the field or armature circuit of the motor, M, which is to be controlled.

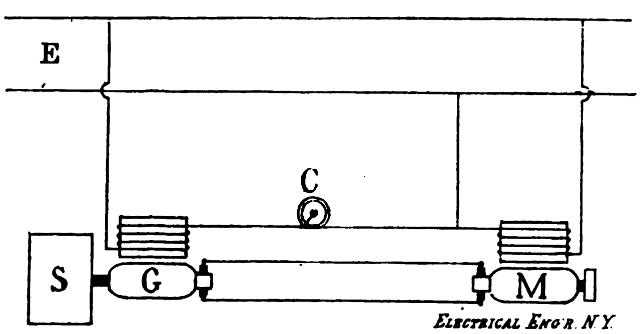

FIG. 1.—LEONARD METHOD OF MOTOR REGULATION.

It will be veident that by varying the field strength of G we can vary the e. m. f. generated in the armature circuit from zero to the full working e. m. f.

The author then showed that when operating the motor at one-tenth of its full speed of 500 revolutions per minute and while under full torque we can throw off the entire load and experience a change in the speed of only 9 revolutions per minute.

He also showed that with rheostat, ohmic resistance control, by the throwing off of the full load, the motor jumps from 41 revolutions per minute to 456 revolutions per minute, a change of 415 revolutions in this case as compared with 9 revolutions in the former case, the change in speed under the same conditions being nearly fifty times as great by the system of ohmic control as by the system of e. m. f. control.

He called attention to the fact that in the speed control by ohms the operator can, by moving the lever of his rheostat, change the volts upon M as fast as he can move his hand. This is a frequent cause of burning out of armatures.

When, however, the change in e. m. f. at the motor is due, as in the case of Fig. 1, to a change of field magnetism, the instantaneous throwing of the lever of the controller does not result in an instantaneous change of e. m. f. at M; for a change of current through G's field results in a gradual although sufficiently rapid change of e. m. f. at G's brushes, and hence the armature of M has a chance to accelerate and develop a counter e. m. f., which, in practice, will never be greatly different from that impressed.

A modification of the general system was also discussed, in which the source of e. m. f. is composed of several different generators in series with each other and having a system of several conductors, upon each of which a different constant potential is maintained, so that by connecting the motor armature across different conductors, different e. m. f.'s are obtainable at the motor armature. With two generators and three conductors three reversible, different automatic speeds can be obtained. Similarly with three generators and four conductors we can get six reversible, different automatic speeds. This modification of the system is especially suited to the distribution of power in an isolated plant such as a large manufacturing establishment.

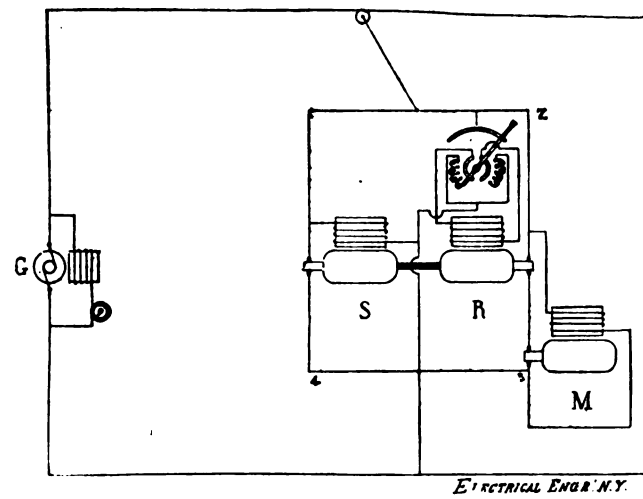

FIG. 2.—LEONARD METHOD OF MOTOR REGULATION.

The author found, when considering the case of the rheostat control with the motor running at 1 ÷ 10 speed and with 100 amperes through it, that the rheostat had to absorb and dissipate 100 amperes × 220.5 = 22,050 watts, while only 2,450 watts were utilized in the motor. This loss in the rheostat is troublesome, not only because of the waste of energy, but especially because of its interference with all positive control. Evidently what is needed is to substitute for the rheostat a device which will absorb the 220.5 volts and 100 amperes, and, instead of wasting them, convert them into useful work.

Fig. 2 shows how this is accomplished by one modification of the e. m. f. system of motor speed control. G is a source of 125 volts constant e. m. f. S is a shunt-wound dynamo connected across the constant e. m. f. and hence running at a constant speed. R is a dynamo mechanically connected to drive or be driven by S, and running at a practically constant speed. The field of R is excited by the main line e. m. f. and is independent of the e. m. f. of its armature and of the current through its armature. It has a variable and reversible field rheostat in circuit by means of which the magnetism of the field of R may be varied and reversed at will. M is the working motor. Its armature is in series with the armature of R across the line. Its field is excited by the main line e. m. f., and hence is independent of the e. m. f. or current of the armature, M.

The author described the action of the combination when a speed variation and reversal is desired.

By weakening of the field of R, we finally have a field of no strength, and hence R becomes inert and we have the full line e. m. f. of 125 volts upon the 250 volt motor, M, which, consequently, runs at half-speed. Under these conditions no energy is transformed by the rotary transformer, RS. If, now, we reverse the connections leading current to the field of R, and send a gradually increasing current around its field, its voltage is added to that of the line instead of being counter as heretofore, until finally its full voltage of 125 being added in series with the line e. m. f. of 125 volts we have upon M 250 volts, and it runs at its full speed. While R is thus adding to the line volts it of course is acting as a generator instead of a motor, which it formerly was, and is now driven by S which acts as a motor instead of a generator. The author called attention to the fact that the current capacity of all three armatures, R, S, and M, is equal, but the full e. m. f. of R and S is only half that of M, which means that the k. w. capacity of R and S is each only half that of M.

The author added a list of installations, in which his system is applied, including elevators, hoists, cloth printing presses, turrets, etc.

THE ILLINOIS INSULATED WIRE COMPANY, Sycamore, Ill., is to erect a $115,000 plant for the manufacture of insulated wire.

[1] Abstract of a paper read before the American Institute of Electrical Engineers, Nov. 18, 1896.

THE NEW PLANT OF THE NIAGARA FALLS HYDRAULIC POWER AND MANUFACTURING CO.

BY ORRIN E. DUNLAP.

THE new electric power plant built by the Niagara Falls Hydraulic Power & Manufacturing Company at the water's edge in the gorge at Niagara has been completed and the machines are in operation. This plant was erected for the purpose of supplying the new aluminum factory of the Pittsburg Reduction Company with power, as well as for generating power to be used for other purposes. The power house is a stone structure 100 feet wide and 60 feet long, and the plans of the company contemplate its extension until it shall be 180 feet in length, work on this extension now being under way. In height the power house is one story, the roof being supported by an iron truss, thus leaving the floor free of all posts. In this power house four wheels made by James Leffel & Company, of Springfield, Ohio, and eight electric generators have been installed. Six of these generators were made by the Westinghouse Electric Manufacturing Company, and two of them by the General Electric Company. A traveling hand crane reaches all parts of the floor, and was a valuable aid in setting the machinery. This crane was made by the Structural Steel Works, of Buffalo. The four water wheels stand on the floor, and receive their supply of water through five-foot inlet pipes connected with the penstock. Each wheel has its individual inlet pipe and water supply, and each and every one of them can therefore be operated alone. In the inlet pipes there are 60-inch valves operated by hydraulic pressure. These valves were made by R. D. Wood & Co., after plans drawn by Wallace C. Johnson, M. Am. Soc. C. E., chief engineer of the Niagara Falls Hydraulic Power & Manufacturing Company. Mr. A. F. Sparks, engineer of the James Leffel Company, designed the wheels, and they are models of beauty. Each wheel weighs about fifty tons, and they are supported on double steel beams resting on solid stone foundations. James Leffel & Co. call this wheel their Niagara type. It is a double discharge turbine and consists of a large, flattened, vertical, circular casing containing the guide case of the wheel proper. Through the supply pipes below the water is let into this exterior casing, flowing upwards and surrounding the guide case. A series of oscillating guides, which constitute the gates, admit the water to the runner. The discharge pipes project from the sides of this casing, laterally and down by a gradual curve, to draft tubes 20 feet in length, thus utilizing a portion of the atmospheric pressure. The heads of the large casing are made of 3½-inch cast iron and are of curved form and shape. The straight or cylindrical part of the case is made of steel plates ¾ of an inch thick, double riveted to the cast heads. Within this casing and the guide casing the runner or wheel proper is located on a horizontal shaft, which is supported by adjustable ball and socket oil bearings on heavy arched bridge trees exterior to the outer casing. The runner is made of bronze and iron, and is 74 inches in diameter. The buckets are made of bronze, and receive the water by a sharp dividing ridge, the central portion, upon which the shell is fastened, being of iron. The water is discharged from the wheels laterally into the discharge pipes, and owing to the design of the wheels there is no uncompensated pressure on any part of the wheel, and no end thrust or pressure on the shaft, the whole being in perfect balance wherever it touches water. The head under which these wheels operate is about 210 feet, the highest at Niagara. The gates are made of the best steel, and are of the James Leffel pattern. They are operated by a patent double ring arrangement which places them easily within the control of a hand wheel operated by one person. The governors in use are made by the Lombard Water Wheel Governor Company, of Boston.

The six generators installed for the Pittsburg Reduction Company by the Westinghouse Electric & Manufacturing Company are all alike, each being of 560 kilowatts capacity, designed to generate 2,000 amperes at 280 volts, while operating at 250 revolutions per minute. They were installed under the supervision of Mr. W. K. Dunlap, the Niagara Falls representative of the Westinghouse Company, and are directly connected by flexible couplings to the shafts of the three James Leffel turbines which operate them. The field of each of these machines consists of eight laminated steel pole pieces cast into a circular yoke or frame. Punched steel discs of carefully annealed steel compose the armature core, which is built upon an iron spider, which also carries the commutator. The periphery of the armature is slotted to receive the winding, which is composed of copper bars held in slots by retaining wedges of hard fibre. Should it become necessary to remove an armature coil, these wedges can be taken out very easily, as they are driven into the notches near the top of the slot, longitudinally with the armature. There is a constant circulation of air through the spider and armature core while the machines are running, as ventilating spaces are provided. Carbon brushes are used, the brush holders being supported by a casting secured to the bearing. The commutators are made of rolled copper, the segments being spaced by prepared mica.

Mr. I. R. Edmands, who represents the General Electric Company at the Falls, installed the two generators built by his company for this plant. They are firmly connected to the water wheel and make 300 revolutions per minute. The General Electric Company's generators are each of 750 horsepower, and give 1,000 amperes at 550 volts. They are com-

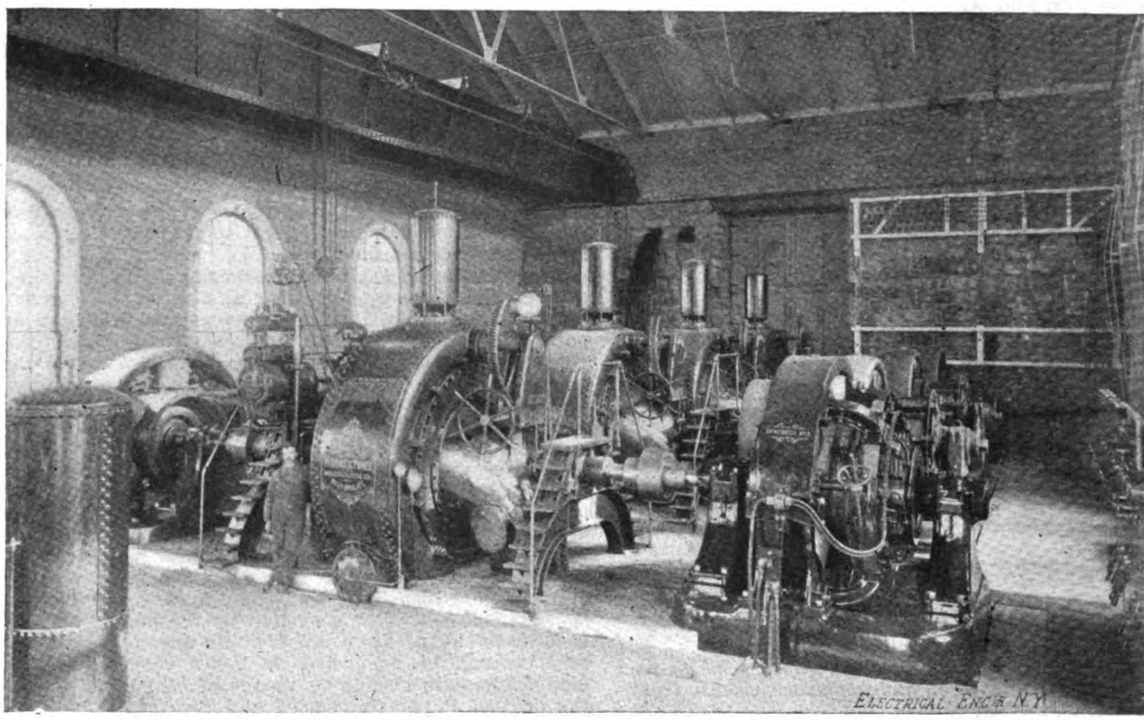

FIG. 1.—INTERIOR OF NEW POWER HOUSE, NIAGARA FALLS HYDRAULIC POWER AND MANUFACTURING CO.

pound wound for railway service, and are to be run in multiple. The Niagara Falls Hydraulic Power and Manufacturing Company now supply the Niagara Falls and Lewiston Railroad and the Lewiston and Youngstown road with electric power, and for this service another generator of General Electric make is used as a "booster," standing on the power house floor, not far from the generators; it is most serviceable. In addition to this some of the current from these generators is used about the city. The switchboard for the General Electric Company's apparatus is made of Vermont marble, Weston ammeters and standard General Electric circuit breakers being used.

The water supply of this plant comes from the upper Niagara River, and flows through a canal 4,400 feet long, 70 feet wide

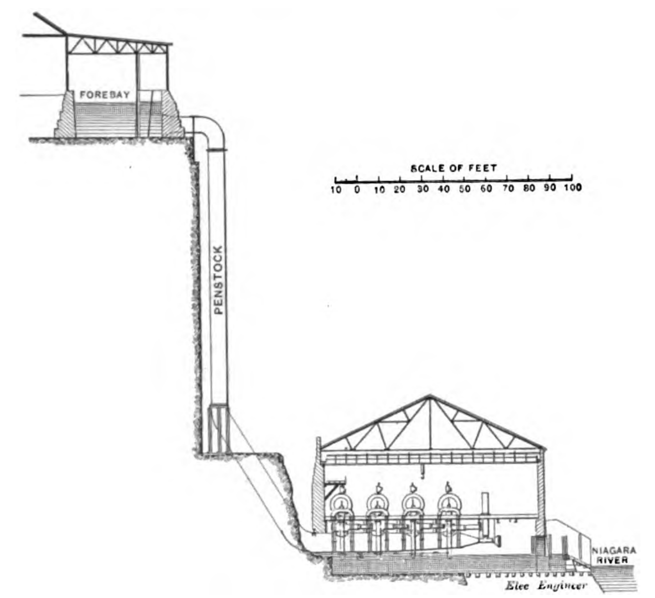

FIG. 2.—NEW POWER HOUSE OF NIAGARA FALLS HYDRAULIC POWER AND MANUFACTURING CO. SECTIONAL VIEW.

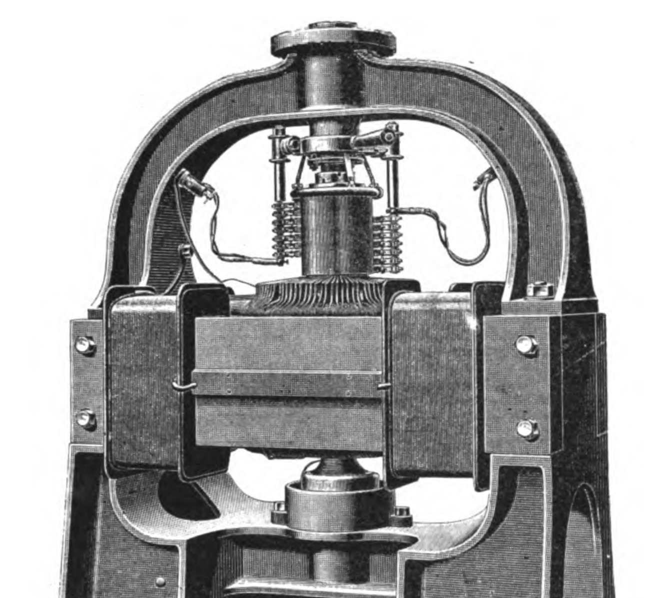
and 11 feet deep, to a basin 400 feet long and 70 feet wide. which runs parallel to the high bank. Preparatory to the construction of this power plant another canal 275 feet long, 16 feet wide and 20 feet deep, was constructed to carry water from the basin referred to to a forebay 180 feet long, 30 feet wide and 22 feet deep, built at the edge of the high bank. The south end of this forebay is closed by a wooden dam, the idea being to extend the forebay at some future time when another connection will be made between it and the canal basin. The gate house stands over this forebay, and here are the gates by which water is let into the penstock, after having passed through screens to remove floating substances. The apparatus for handling these gates is the pride of Engineer Johnson, for it was designed by him. In front of each pair of gates stand two cast iron cylinders containing a piston, and about eight feet high. A pump operated by an electric motor is connected to the tops and bottoms of these cylinders, and by this means oil can be forced into the top or bottom of the cylinders as desired. The piston rods of the two cylinders are connected at the top by an iron beam carrying four heavy iron hoops, and these hoops take hold of pins in the gates. By running the pump and adjusting the valves, the gates may be raised or lowered, opened or closed, and one or both gates may be handled at a time. Beneath the gate house there is also a waste gate, built for the purpose of cleaning the canal. This gate consists of two gates, each eight feet wide and twenty feet in length. In length the gate house is 180 feet and its width is 46 feet. It is an iron frame structure covered with corrugated iron. The penstock that carries the water supply to the wheels is eight feet in diameter and made of the best quality steel plate. In leaving the forebay it runs in a horizontal direction for about 25 feet to clear the edge of the bank, and then it extends in a vertical direction 125 feet to a solid foundation on the lower Niagara limestone. It then runs at an angle of 45 degrees to the power house building, extending under the floor about 70 feet, for which distance it is 10 feet in diameter. At the top the steel plate of the penstock is 5-16 of an inch thick, and at the bottom it is 15-16 inches in thickness. In passing beneath the power house floor the penstock runs through the tail race, in which it hangs suspended by 48 iron rods, each 1½ inches square, supporting a weight of at least 300,000 tons. The pressure on the lower portion of this penstock is 100 pounds to the square inch. The tail race is formed by two masonry walls standing 17½ feet apart and extending from a point six feet below the water in the river back to a point 20 feet above or to the power house floor.

The current from the generators of the Pittsburg Reduction Company flows into copper bus bars from which it is conducted by 500 aluminum wires forming two cables up to the top of the bank to the pots of the new aluminum plant. This building is of iron and of good sized dimensions, its capacity being about 5,000 pounds per day. Mr. W. S. Ferguson is the superintendent. This factory is a very substantial addition to the possessions of the Pittsburg Reduction Company, at Niagara Falls, and is destined to add materially to the world's output of aluminum. The company now distinguish their Niagara plants by calling them the Upper and Lower works.

The superintendent of the new power plant is Mr. F. G. Lott, who also has charge of the plant of the Buffalo Electric Light and Power Company. Mr. Lott has had charge of the electric part of the work on behalf of the power company. The formal opening of the plant took place on Monday, Nov. 23, when many prominent citizens of Buffalo and Niagara Falls visited the power house by invitation of Mr. Arthur Schoellkopf, the local head of the company, and admired the installation, which is beyond doubt the greatest improvement the company have made to their power property since they bought it in 1877. The years which have passed since the organization of the Niagara Falls Hydraulic Power and Manufacturing Company have been busy ones for them, for they have expended many thousands of dollars in the enlargement of their waterway and the development of its energy. The new plant is of unusual importance because it outlines and defines the success of a valuable method of developing Niagara's force.

MOTOR FOR DRIVING CENTRIFUGAL PUMP.

We illustrate on this page one of a set of eight electric motors constructed by Messrs. Ernest Scott & Mountain, Limited, of the Close Works, Newcastle-on-Tyne, for driving the centrifugal pumps used for clearing water from a large floating dock . As will be seen the armature axis is placed vertically, being fitted with a coupling below to bolt on to another flange on the pump spindle. The field magnets are



MOTOR FOR DRIVING CENTRIFUGAL PUMP.

bolted to a heavy cast-iron standard which also supports the bearings of the armature spindle. The commutator is located on the upper portion of the machine, being therefore easily accessible. The motors are designed to run at 350 revolutions per minute, at which they develop 60 effective horse-power. We are indebted to London "Engineering" for the accompanying illustration.

THERMO-ELECTRICITY.

THE ACTION IN THE JACQUES CARBON CELL.

BY C. J. REED.

I HAVE read with great interest the article in The Electrical Engineer of Nov. 25, on the "Jacques Carbon Generator." I believe that, accepting the data now published by Dr. Jacques, there can be no further discussion as to the efficiency of the battery devised by Dr. Jacques. Its commercial utility will depend entirely upon his success in dealing with the "many details to be worked out and many improvements yet to be made, before the carbon electric generator can be put into commercial use on a scale comparable with that of modern steam engines." The results now given by Dr. Jacques are certainly most gratifying and encouraging, if we consider only the question of weight of material consumed; and it is to be hoped that Dr. Jacques will succeed as well in overcoming the other practical difficulties, such as the expense of getting the carbon into a suitable form, of maintaining the electrolyte in its proper condition and of protecting the apparatus from destruction.

As to the nature of the reaction that takes place within the cell and the origin of the electromotive force—whether it be galvanic or thermo-electric—the additional data furnished by Dr. Jacques gives us little, if any, assistance in arriving at a conclusion.

The fact that carbon dioxide is formed and that oxygen and carbon are consumed and that the theoretical current and voltage are obtained is no indication that the action is not thermo-electric, but rather an indication that it is thermo-electric. If the current obtained corresponds exactly to the electro-chemical equivalent of the carbon consumed and the carbon dioxide produced (which seems to be the case in the Jacques cell), there seems to be but one answer to the question, viz., that the action is thermo-electric and that the oxidation of the carbon is due to the electrolytic action of the thermo-electric current. In that case the energy of the carbon would be consumed in maintaining the electromotive force on closed circuit, provided no hydrogen or metal were allowed to pass out of the electrolyte; that is, provided there is no reduction of hydrogen or metal to the metallic or other insoluble state. If hydrogen or any other metal passes by reduction out of solution in the electrolyte, the energy of the carbon will first supply that absorbed by the reduction, and if a balance remains, that balance will go towards maintaining the electromotive force on closed circuit. Such a reaction should be very economical, but could not take place with evolution of energy in an electrolyte consisting of pure caustic alkali, since the reduction of either hydrogen or the alkali metal (the only reducible constituents) would require the absorption of more energy than that contained in the carbon.

If the carbon dioxide produced is in excess of the electro-chemical equivalent of the current, there must be oxidation independent of any thermo-electric current, that is, spontaneous oxidation. Such action could be galvanic only where the oxygen is derived from the decomposition of the electrolyte, as, for instance, from the reduction of hydrogen or a metal. In the Jacques cell this could not occur if the electrolyte were pure caustic alkali, for the reason that the carbon could reduce the hydrogen or alkali metal only by the absorption of energy, not by its evolution.

If the action in the Jacques cell is galvanic, that is, if the chemical action is spontaneous and not a result of electrolysis, the chemical action will continue to take place on the carbon after it has passed out of the electric circuit. Therefore particles of carbon that necessarily become detached by the mechanical disintegration of the electrode will continue to be consumed and to evolve carbon dioxide. The quantity of carbon consumed and of dioxide formed will, therefore, necessarily be greater than that corresponding to the electrical energy evolved.

If, on the other hand, the action of the cell is thermo-electric and the chemical action a result of electrolysis, no carbon can oxidize after it has passed out of the electric circuit, and the detached particles could undergo no oxidation. The quantity of carbon consumed and of dioxide produced would in that case be the exact equivalent of the current, as in other electrolytic reactions. That the action is thermo-electric appears to be established by results obtained by Dr. Jacques. He says:

"Later experiments with far larger apparatus have not only confirmed these results, but have shown that under proper conditions the electrical energy obtainable from one of these generators is substantially equal to the potential energy of the weight of carbon consumed in the pot."

The only theory of the action of the Jacques cell, which seems to satisfactorily account for all the facts that have been observed, is that suggested by Prof. Elihu Thomson[1]. This theory is in substance that the electrolyte, instead of being pure caustic alkali, contains oxide of iron, or in other words, is a fused alkaline ferrate. This electrolyte supplies oxygen by reduction of the iron (either to the metallic state or to a lower oxide), and is regenerated by the atmospheric oxygen, which reoxidizes to alkaline ferrate the reduced iron. This electrolyte satisfies either the thermo-electric or the galvanic theory; but the quantitative results obtained by Dr. Jacques, as quoted above, appear to exclude the galvanic, and limit us to the thermo-electric theory. I would suggest that the validity of the theory may be tested by substituting a silver crucible for the iron pot of the Jacques cell and using caustic alkali free from iron and other impurities and a silver tube for the introduction of air. With such an apparatus I venture the prediction that no electrical energy will be obtained from the consumption of "carbon within the pot."

Whatever theory finally proves to be correct as to the nature of the action in this cell, it cannot, of course, in any way detract from nor add to the value of Dr. Jacques' discovery, if he succeeds in obtaining a commercial efficiency of 32 per cent.

SOCIETY AND CLUB NOTES.

NATIONAL CONFERENCE ON ELECTRICAL RULES.

AT the joint conference of electrical, insurance and allied interests looking toward the adoption, promulgation and enforcement of a national code of rules for electrical construction and operation, which was held March 18 and 19 of this year at the headquarters of the Am. Soc. of Mechanical Engineers, this city, a large amount of work was done; and after a permanent organization to be known as the "National Conference on Standard Electrical Rules," had been effected with headquarters at 12 West Thirty-first street, New York, it was decided to place the work of drafting the final code in the hands of a committee of eight, including the president (ex-officio), who were to report back to the next meeting of the National Conference. This committee consisted of the following gentlemen: Prof. Francis B. Crocker, chairman, delegate Am. Ins. of Elec. Engineers; Frank R. Ford, secretary, delegate Am. St. R. R. Association; William Brophy, delegate National Elec. Lt. Association; William H. Merrill, Jr., delegate National Board of Fire Underwriters; E. A. Fitzgerald, delegate Underwriters Nat. Elec. Association; Alfred Stone, delegate Am. Ins. of Architects; E. V. French, delegate Am. Factory Mutual Ins. Cos.; W. J. Hammer, ex-officio.

This committee have recently met in New York and spent two days upon the preparation of the code and then adjourned to meet again Dec. 11 and 12, this date being decided upon in order to enable the Underwriters' National Electric Association, which meets in this city Dec. 8 and 9, to consider the suggestions already made by the code committee, to secure their criticisms and co-operation in the matter. It is expected that shortly after the next meeting of the code committee, the National Electrical conference will be called to take action upon the code prepared by the committee.

It is gratifying to observe that the various engineering societies and the strong representation of the insurance organization, represented in the National Electrical Conference, are working so harmoniously and with so much energy to bring about the single national code of rules.

ELECTRICITY AND THE HUMAN BODY.

Before the Department of Electricity of the Brooklyn Institute., on Friday, Dec. 4, at the Art Building, Dr. W. M. Hutchinson will lecture on "Electricity in its relation to the human body." The lecture will be illustrated by lantern photographs and experimental demonstrations.

ANNUAL MEETING CONNECTICUT STREET RAILWAY ASSOCIATION.

The annual meeting of the Connecticut Street Railway Association was held at New Haven on Nov. 18. Rrepresentatives were present from all the New Haven, Hartford, Bridgeport, Waterbury, New Britain, Derby, Bristol and Norwalk lines and from the Westport and Saugatuck road. The election of officers resulted as follows: President, H. Holton Wood, Der-

[1] Jour. Franklin Institute, Nov., 1896.

by; vice-president, Henry S. Parmelee, New Haven; secretary, E. S. Breed, New Britain; treasurer, E. S. Goodrich, Hartford; executive committee, A. M. Young, of Waterbury; Israel Kelsey, of West Haven, and G. W. Dodge, of this city.

A general discussion followed on matters of interest to street railway officials. The delegates inspected the street railway lines of the city and at 2:30 o'clock the annual banquet was held in the New Haven House.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Central Stations:

ELECTRICITY WORKS AT JEVER, OLDENBURG.—A small municipal plant. It is described in detail, but is simply a typical small German station with its accumulators.—"Elektrot. Zeitschr.," Oct. 8, '96.

ELECTRICITY WORKS, ZURICH.—Abstract of the annual report for '95, of the works. The increase of lamps, motors, and other apparatus amounts to 60 per cent. for one year.—"Elek. Zeit.," Oct. 22, '96.

THE DOUGLAS SOUTHERN ELECTRIC TRAMWAY.—In one of the finest sections of the Isle of Man, the trolley system is being gradually developed. The plant is not a very large one, two 100 kilowatt generators supplying the power. Details in Lond. "Lightning," Oct. 29, '96.

BURY ELECTRICAL WORKS.—A municipal undertaking. Details of plans are described and illustrated. The three-wire low tension system was adopted. Accumulators are used in connection with the system.—Lond. "Elec. Eng'r.," Nov. 6, '96.

Dynamos and Motors:

OERLIKON THREE-PHASE ASYNCHRONOUS MOTORS.—A general description of the principal standard types manufactured by this company.—Lond. "Elecn.," Oct. 30, '96.

Educational;

LECTURES ON ELECTRICAL ENGINEERING IN THE GERMAN TECHNICAL HIGH SCHOOLS DURING THE WINTER TERM, '96 & 97.—The schools in Berlin, Braunschweig, Darmstadt, Dresden, Hanover, Karlsruhe, Munich and Stuttgart are mentioned, with the names of the instructors, their subjects and the number of hours per week.—"Elek. Zeit.," Oct. 8, '96.

Electro-Physics:

COMPLETE APPARATUS FOR THE STUDY OF THE PROPERTIES OF ELECTRIC WAVES.—By J. Chunder Bose, M. A., D. Sc. Read before the Brit. Assoc., Section A. Author exhibited instruments with which he was able to obtain the values of the indices of refraction of various substances for electric waves, the wave length of electric radiation, and to demonstrate the phenomena of double refraction and polarization of the electric ray. The complete apparatus consists of: (1) A radiating apparatus emitting electric waves of short lengths; (2) a receiver used as a detector of electric radiations; (3) various accessories for the study of the different phenomena. These are described in detail in the Lon. "Elecn.," Oct. 16, '96.

Lighting:

THE LOCALIZATION OF FAULTS IN ELECTRIC LIGHT MAINS.—By F. C. Raphael. Continuing previous articles, author devotes this section to the finding of faults on series arc lamp circuits by the potential and loop methods, and commences a section on fault signaling networks.—Lond. "Elecn.," Oct. 16, '96.

Measurements:

MEASUREMENTS OF EARTH RESISTANCE OF HIGH TENSION CURRENT BY MEANS OF THE LINE VOLTAGE.—By Dr. Oscar May. Author explains the use of the voltmeter and milliamperemeter in this connection.—"Elek. Zeit.," Oct. 22, '96.

EFFECT OF INSULATION RESISTANCE AND CAPACITY ON THE ABSOLUTE POTENTIALS IN ALTERNATE CURRENT SYSTEMS.—By A. von Ettinghausen and G. Ossana. Authors give the results and their methods of procedure in testing several three-phase power plants.—From the "Zeit. f. Elek.," in Lond. "Elec.," Oct. 30, '96.

ON THE PROTECTION OF THE MIRROR GALVANOMETER AGAINST DISTURBANCES OF EARTH CURRENTS.—By Dr. Classen. A simple device will accomplish the required result. Two small iron wire bunches are brought close to the astatic needles and are arranged so that they can be easily raised or lowered and thus counterbalance the varying earth current.—"Elektrot. Zeitschr.," Oct. 29, '96.

Miscellaneous:

KINETOSCOPE STEREOPTICON.—Popular explanation of this new fad, embracing under one general heading all the various types, such as vitascope, cinematograph, etc.—"Scient. Am.," Oct. 31, '96.

VEERING DRUMS FOR LIGHTSHIPS.—Capt. H. Benest has devised a form of veering drum in connection with the problem of telegraphic communication with lightships. The object in view, is to provide lightships, which are fitted with an electric cable, with means for automatically securing the normal condition of twist in the electrical cable, while the vessel swings around under the action of the shifting tide or wind. For a clear understanding of this subject see the illustrated description in Lond. "Elec. Rev.," Oct. 30, '96.

Power Transmission:

GENEVA ELECTRICAL WORKS.—Special turbines had to be designed to take care of the wide ranges of water flow between summer and winter. The regulator will with a very small angular motion entirely cut off the water. The top of the main shaft supports a cast iron bell, which takes the place of the field magnets of the alternator. This enormous weight is lifted by oil under pressure to reduce friction. The transmission line of 4½ miles is entirely underground.—Lond. "Elec.," Oct. 30, '96, "Elec. Engr.," Dec. 2, '96.

COST OF CURRENT TO THE CONSUMER.—An editorial explains a new method of charging for current, introduced by the Electricity Works of Upper Silesia, and one which seems to meet with general approval. Up to a certain number of kilowatt hours, a certain price per k. w. hr. is charged; everything above that is furnished for smaller sums.—"Elek. Zeit.," Oct. 1, '96.

SWITZERLAND FOR THE YEARS 1894 AND 1895.—By Dr. Denzler. The summary of the statistics is as follows:

	1895.	1893.	1889.
Lighting installations	866	677	351
Transmission plants	121	77	25
Accumulator batteries	248	161	41
Dynamos and motors	2,553	1,404	536
Total capacity in kilowatt	58,485	28,831	7,060
Incandescent lamps	212,568	145,984	51,155
Arc lamps	2,714	2,126	845

—"Elek. Zeits..," Oct. 1, '96.

GERMAN ELEVATOR SERVICE.—By G. Speiser. Author illustrates and explains the automatic starting and stopping devices of the E. A. G.'s elevator motors for freight and passenger service.—"Elek. Zeit.," Oct. 15, '96.

THE FIRE RISK IN BELT TRANSMISSION OF POWER.—By Wm. Elmer, Jr. The writer points out how many fires occur from some unknown cause and the blame is laid to poor wiring, whereas in many cases it may be shown that it was really caused by a hot journal or by the belting rubbing gainst some inflammable material.—"Elec. World," Nov., "Am. Gas Light Journ.," Nov. 16, '96.

A LONG-DISTANCE POWER TRANSMISSION SCHEME.—Keewatin Power Co., intend to transmit power from Keewatin to Winnepeg, a distance of 120 miles, using from 25,000 to 30,000 volts. They are now preparing specifications.—Editorially mentioned in "Can. Elect. News.," Nov., '96.

TRANSMISSION PLANT EICHDORF-GRUNBERG.—By Walter Klug. A 10,000-volt three-phase transmission plant with many points of special interest. Current is generated at 250 volts and transformed there to 10,000. Triple petticoat insulators are used and a special type of lightning arrester is introduced. For details of plant as well as diagrams and plans, see "Elektrot. Zeitschr.," Nov. 5, '96.

Railways:

A RAILWAY POWER HOUSE TRANSFORMED.—The plant of the Cicero and Proviso Street Railway Company in the Western suburbs of Chicago has undergone such changes during the last five years that it stands to-day as one of the most modern plants. For details see "West. Elec.," Nov. 14,'96.

Roentgen Rays:

NOTE ON A CATHODE RAY SPECTRUM.—By M. Birkeland. The principal observations of the author are: 1, When the primary current is continuously increased, the magnetic deflection of all the bands diminishes, so that they draw nearer to one another; 2, when the pressure in the tubes is

diminished, the primary current remaining constant, the magnetic deflection of the cathode rays also diminishes continuously, first quickly, then slowly, as if toward a limit.—From "Comptes Rendus," No. 13 in Lond. "Elec.," Oct. 16, '96.

THE NATURE OF THE ROENTGEN RAY.—Sandrucci, an Italian physicist, has made a series of experiments to determine whether the rays act directly on the photographic film or indirectly, by producing phosphorescence in the glass in contact with the film. Results show the first to be the case.—Lond. "Elec. Rev.," Oct. 30, '96.

DISTRIBUTION OF ELECTRICITY ON THE SURFACE OF CROOKES AND GEISSLER TUBES.—Villari, an Italian scientist, sifts over the surface of a tube a mixture of powdered sulphur and red lead; the latter will adhere to the negatively charged, the sulphur to the positively charged surface. It is found that the center of the tube is covered with the lead in irregular figures, while the rest of the tube distributes the sulphur uniformly over the surface. A neutral space separates the sulphur from the red lead.—Lond. "Elec. Rev.," Oct. 30, '96.

Wires, Wiring, Etc.:

DISSIPATION SHEETS AND WIRES.—This article points out the difficulty of close calculation on account of the many experimental coefficients required. It gives, however, some general points for calculating the size for dissipation sheets, dissipation wires and a general résumé of some practical dissipators.—Lond. "Elecn.," Oct. 30, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED NOV. 17, 1896.

Alarms and Signals:—

ELECTRIC SIGNAL BOX. W. W. Hibbard, Rochester, N. Y., 561,441. Filed June 16, 1894.
Comprises two signal boxes set one within the other and separated by a clear space, four spiral springs at the corners connecting the boxes and sustaining the interior one, and insulators around which the springs rest.

ANNUNCIATOR. F. A. Jennings, Ithaca, N. Y., 571,445. Filed May 11, 1895.
Designed to be used to indicate the time status of railway trains.

TRACK INSTRUMENT. T. B. Dixon, Henderson, Ky., 571,472. Filed Nov. 15, 1895.
Means for counteracting the effect of residual magnetism in the magnetic conductors. For railroad signaling.

ELECTRIC SIGNALING SYSTEM. J. P. Buchanan, Boston, Mass., 571,507. Filed Feb. 5, 1894.
Comprises a signal falling by gravity into "danger" position, and an electromagnet arranged to operate the signal to put it to "safety."

Batteries, Primary:—

PRIMARY BATTERY. S. N. Smith, Minneapolis, Minn., 571,460. Filed Nov. 16, 1895.
Details of construction.

Batteries, Secondary:—

MANUFACTURE OF PLATES FOR ELECTRIC ACCUMULATORS. J. Kerner, Mannheim, Germany, 571,598. Filed Jan. 6, 1896.
A protective layer of sulfate of potash is deposited on the plate, and then the active material or paste is applied.

Conductors, Conduits and Insulators:—

ELECTRICAL SWITCH CONDUCTOR. W. H. Sawyer, Providence, R. I., 571,539. Filed Aug. 12, 1896.
An electrical conductor composed of an elastic rubber core, surrounded by a braided web carrying one or more wires and the whole inclosed within a suitable wound covering. Intended for telephone switchboard cords.

CABLE TERMINAL BOX. W. H. Johnston, St. Louis, Mo., 571,504. Filed Sept. 14, 1896.
An arrangement whereby the conductors of one cable may be brought without intermediate wiring into connection with another cable, each cable being protected by a distinct cable head.

ELECTRIC CABLE. S. P. Thompson, London, England, 571,706. Filed July 20, 1892.
Comprises two or more insulated conductors running therethrough side by side and provided at intervals with compensating devices for diminishing the electrostatic capacity.

ELECTRIC CABLE. S. P. Thompson, London, England, 571,707. Filed July 20, 1892.
Consists in dividing the circuit into a series of successive separately insulated metallic return circuits, in each of which a movement of electricity takes place, and in connecting these circuits by mutual induction.

Dynamos and Motors:—

COMMUTATOR BRUSH. A. K. Warren, New Brighton, N. Y., 571,420. Filed May 15, 1896.
Consists of material adapted to rub on a commutator ,an extension piece of similar cross-section to the brush, and means for fastening the brush and extension together.

ALTERNATING CURRENT MOTOR. M. Hutin and M. Leblanc, Paris, France, 571,478. Filed May 25, 1895.
Comprises an electric circuit possessing self-induction, charged with alternating currents, an electrolytic polarization battery having a sufficient number of cells in series to neutralize by polarization the electromotive force of the self-induction in the circuit.

Electro-Metallurgy:—

MAGNETIC SEPARATOR. J. B. Hamilton, Springfield, Mass., 571,362. Filed Dec. 5, 1893.
Designed for the extraction of iron particles from pulp in the manufacture of paper.

PROCESS OF PRODUCING COATINGS COMPOSED OF EARTHY OXIDS, 571,532. Filed Nov. 29, 1895.
Consists in electrolyzing a dilute aqueous solution of metahydroxid of an alkali earth metal by an electric current of low density depositing thereby upon an electroconductive foundation a coating of hydroxid and finally drying and calcining the deposit.

ELECTROLYTIC PROCESS OF CONVERTING HYDROXIDS OF EARTH AND EARTH ALKALI METALS INTO INDISSOLUBLE ORGANIC OR INORGANIC SALTS, ETC. R. Langhans, Berlin, Germany, 571,533. Filed March 28, 1896.
Consists in placing a coated foundation as an anode in an electrolyte which consists in an aqueous solution of an acid capable of converting the hydroxid coating into a salt which is indissoluble in the bath, but reducible to oxide by the action of heat and electrolyzing by a current of low density.

PROCESS OF PRODUCING COATINGS COMPOSED OF EARTHY OXIDS. R. Langhans, Berlin, Germany, 571,531. Filed Nov. 18, 1895.
Relates to above process.

ELECTRIC FURNACE. A. C. Girard and E. A. G. Street, Paris, France, 571,655. Filed May 24, 1895.
A fixed carbon through which the material to be heated is fed, the carbon tube constituting a common electrode, and one or more other electrodes arranged in proximity to the carbon tube, whereby the material under treatment is separated from the arc.

APPARATUS FOR ELECTROLYSIS OF CHLORIDS, ETC. J. Hargreaves, Farnsworth-in-Widnes, and T. Bord, Cressington, England, 571,591. Filed Jan. 4, 1894.
A cell having opposing porous diaphragms, and an anode and cathode, respectively, located in contact with the exterior surfaces of the diaphragms.

PROCESS OF TREATING ORES. T. P. Barbour, San Antonio, Tex., 571,468. Filed Nov. 7, 1893.
Consists in first treating the raw material with copper oxid and sulfuric acid, then chlorinating the pulp thus treated, introducing the chlorinated mass into a suitable agitator having zinc therein, and establishing an electric current through the mass in the presence of zinc.

Miscellaneous:

ELECTRIC GAS LIGHTING APPARATUS. C. W. De Mott, Brooklyn, N. Y., 571,723. Filed May 8, 1896.
Details of construction.

ELECTRIC ELEVATOR. R. Wilson, Louisville, Ky., 571,502. Filed July 8, 1895.
The combination of a car, an electric motor, two speed controlling rheostats and a solenoid having two independent cores, respectively, operating rheostats.

ELECTRICALLY OPERATED WATER SUPPLY SYSTEM. J. P. Barrett, Chicago, Ill., 571,328. Filed Aug. 31, 1895.
Employs electrically operated pumps which may be thrown into operation when desired to assist the main pumping apparatus.

ELECTRIC THERMOMETER. M. A. Agelasto, Norfolk, Va., 571,426, Filed May 8, 1896.
The temperature is determined by means of change in resistance of a coil by the aid of a Wheatstone bridge.

COMBINED ELECTRIC HYDRAULIC ELEVATOR. J. Parkinson, Los Angeles, Cal., 571,730. Filed April 10, 1895.

COMBINED ELECTRIC HYDRAULC SCREW-CONTROLLED ELEVATOR ENGINE. J. Parkinson, Los Angeles, Cal., 571,731. Filed June 25, 1895.

COMBINED ELECTRIC HYDRAULIC ELEVATOR. J. Parkinson, Los Angeles, Cal., 571,732. Filed Dec. 3, 1895.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. G. J. Forrey, Carlisle, Pa., 571,435. Filed Feb. 29, 1896.
A third-rail system in which the third rail is energized only as the car passes over it.

CABLE CARRIER. E. L. Heidenreich and G. Monrath, Chicago, Ill., 571,440. Filed Aug. 15, 1896.
The improvements are directed more especially to carriers suspended from a cableway and furnished with an electric motor controlled by the operator on the car for hauling logs.

RAIL SUPPORT. W. B. Potter, Schenectady, N. Y., 571,454. Filed Aug. 25, 1896.
Comprises a body of insulating material, a metallic cap having a fixed lug and a removable lug, the two lugs adapted to engage with the flange of the rail, and means, consisting of a slot through the shank of the lug and a tapered pin passing through the slot, for securing the removable lug in place.

RAIL SUPPORT. W. B. Potter, Schenectady, N. Y., 571,455. Filed Aug. 25, 1896.
Similar to above.

AUTOMATIC TROLLEY SWITCH. L. M. Erb, Leavenworth, Kan., 571,517. Filed Feb. 29, 1896.
Comprises a shiftable tongue and a trigger lying in the path of the tread of the trolley wheel and adapted to be moved upward by the upward pressure of the trolley and thereby shift the tongue.

TROLLEY FOR ELECTRIC CARS. S. F. Tufts, Westbrooke, Me., 571,710. Filed Oct. 9, 1895.
Consists in so mounting the contact wheel that it will have a vertical and a lateral motion.

ELECTRIC BRAKE. E. A. Sperry, Cleveland, O., 571,409. Filed June 20, 1896.
Comprises motors operating as generators to supply a braking current and electromagnetic devices, an auxiliary source of electromotive force independent of the motors and the trolley current, and a device for causing the current from the auxiliary source to pass through the brake magnets when the braking current ceases.

ELECTRIC CONTROLLER. E. A. Sperry, Cleveland, O., 571,410. Filed July 31, 1896.
Comprises a contact cylinder, a limit switch mounted on the core of the magnet, an arm for opening the switch, and a cam actuated by a movement of the controller handle for operating the arm.

Regulation:—

ELECTRIC GOVERNOR FOR WATER WHEELS. W. W. Hanly, Baltimore, Md., 571,363. Filed June 19, 1896.
Intended for use in electric plants run by water power. A solenoid acts as the governing medium.

REGULATING POLYPHASE CIRCUITS. A. H. Armstrong, Schenectady, N. Y., 571,467. Filed May 2, 1896.
Consists in combining with the main electromotive force derived from the generating source another constant electromotive force and then varying the phase relation between the main impressed electromotive force and the constant electromotive force from coincidence of phase to direct opposition.
CONTROLLER FOR ELECTRIC PUMPS. F. W. Merritt, Duluth, Minn., 571,600. Filed Feb. 14, 1896.
Means to maintain the pressure at a certain point by breaking the electric circuit of the pump motor when the pressure rises to a certain limit and closing the circuit when the pressure falls to a certain limit.

Switches, Cut-Outs, Etc.:

CONTROLLING ELECTRIC ARCS. E. Thomson, Swampscott, Mass., 571,463. Filed June 26, 1896.
Employs a compound field for acting upon the arc.
MANUFACTURE OF ELECTRICAL RESISTANCES. A. J. Marquand, Cardiff, and D. Lowden, Barry Rock, England, 571,489. Filed June 25, 1896.
Composed of asbestos cloth having deposited in its texture carbon resulting from the decomposition of carbonaceous material in contact with the asbestos cloth.
LIGHTNING ARRESTER. A. de Khotinsky, Boston, Mass., 571,669. Filed Sept. 24, 1896.
Consists of two carbon plates having their proximate surfaces grooved and a centrally slotted non-conducting septum between them, the edges of the slot coinciding with the axial or central lines of the groove.
ELECTRIC CUT-OUT. B. F. Rout, Stanford, Ky., 571,734. Filed March 27, 1896.
Particularly adapted for use in house circuits.

Telegraphs:—

ELECTROMAGNETIC SIGNAL-RECEIVING INSTRUMENT. S. D. Field, Stockbridge, Mass., 571,351. Filed Aug. 11, 1896.
For use in relays and annunciators.
TELEGRAPH SWITCH MECHANISM. F. P. Scott, Terre Haute, Ind., 571,695 Filed March 25, 1896.
The switching mechanism is operated by an electric motor controlled from a distant station.
COIN, CONTROLLER MECHANISM FOR TELEPHONES. R. D. Gallagher, Jr., Chicago, Ill., 571,590. Filed March 14, 1896.

Telephones:—

TELEPHONE TRANSMITTER. D. N. Rowan, Irvington, N. Y., 571,399. Filed Dec. 10, 1895.
Comprises flexible non-conducting shelves, electrodes, and granular conducting material suspended on the shelves between the electrodes.
MICROPHONE TRANSMITTER. E. A. Barkalow and N. Crawford, Kokomo, Ind., 571,504. Filed July 31, 1896.
Employs a carbon pencil within the microphone box running parallel to the transmitter diaphragm .

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED NOVEMBER 24, 1896.

Alarms and Signals:—

ELECTROMAGNETIC SENTINEL. F. B. Badt, Chicago, Ill., 571,739. Filed Feb. 15, 1896.
Means for detecting the approach of a mass of magnetic material, such as armor clad warships.
STATION POTENTIAL INDICATOR. R. D. Mershon, Pittsburg, Pa., 571,839. Filed Dec. 23, 1895.
Comprises a local circuit in which the impressed and counter electromotive forces of the main line are approximately reproduced in miniature, and a voltmeter for indicating the value of the resultant electromotive force.
FIRE ALARM SIGNAL BOX. G. F. Milliken, Boston, Mass., 571,950. Filed Dec. 14, 1891.
The circuit is not opened by the signaling wheel until after a lapse of time longer than the longest closed circuit period of any signal.
BINDING POST FOR ELECTRIC BELLS, ETC. F. W. Manger and O. H. Huebel, Brooklyn, N. Y., 571,977. Filed March 24, 1896.
Means whereby the binding post may be attached which will prevent its turning with the clamping nut.
AUTOMATIC TEMPERATURE ANNUNCIATOR. J. A. Young, Indianapolis, Ind., 572,081. Filed May 11, 1896.
Consists of a suitable base upon which is mounted a temperature thermometer and a suitable mechanism, so connected to a system of wires and batteries that an alarm is sounded by means of a gong when a certain degree of temperature is reached.
ANNUNCIATOR. F. A. Jennings, Ithaca, N. Y., 572,057. Filed May 11, 1895.
Designed to indicate the time status of railway trains.

Conductors, Conduits and Insulators:—

MEANS FOR INSULATING ELECTRIC CONDUCTORS. T. Gilleaume, Mulheim-on-the-Rhine, Germany, 571,760. Filed Nov. 2, 1895.
Relates to conductors with paper and air space insulation; embodies special means of maintaining the air spaces and protecting the walls of the latter against crushing.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. O. B. Shallenberger, Rochester, Pa., 571,849. Filed Nov. 8, 1886.
Comprises a potential reducing converter connected in supply circuit, two or more secondary circuits derived from the converter, consuming circuits connected with the secondary circuits at different points, and translating devices connected in the consuming circuits.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. W. F. Marzahn, Buffalo, N. Y., 571,780. Filed Sept. 21, 1896.
Embodies a drum armature, with ventilating tubes disposed in the ends thereof.
WHEEL WITH ELECTRICAL MOTOR HUB FOR VEHICLES. C. Theryc, Marseilles. France, 572.036. Filed July 31, 1896.
Intended for bicycles.
SPEEDING DEVICE FOR RACE TRACKS. H. G. Wilshire, Los Angeles, Cal., and M. C. Massie, Washington, D. C., 572,080. Filed May 12, 1896.
INDUCTOR DYNAMO. C. P. Steinmetz, Schenectady, N. Y., 11,576, re-issued. Filed May 5, 1896.
Comprises inwardly projecting pole pieces provided with field magnet windings, armature coils mounted upon the polar faces, and a revolving inductor.

Lamps and Appurtenances:—

SWITCH FOR ELECTRIC LAMPS. H. R. Quinby, Rochester, N. Y., 571,791. Filed Dec. 4, 1895.
Hanger-board switch.
ELECTRC ARC LAMP. H. R. Quinby, Rochester, N. Y., 571,792. Filed March 12, 1896.
Feed mechanism for lamps of the enclosed arc type.
ELECTRIC ARC LAMP. C. Eschwel, Long Island City, N. Y., 571,946. Filed Sept. 11, 1896.
Relates to the feed mechanism.
ELECTRIC ARC LAMP. G. R. Lean, Cleveland, Ohio, 571,974. Filed May 23, 1896.
Details of construction.
ELECTRIC ARC LAMP. G. R. Lean, Cleveland, Ohio, 571,976. Filed July 7, 1896.
The combination with a depending arm, and a yoke at the lower end of the arm, of an outer-globe holder removably connected to the yoke, and an inner or arc inclosing globe holder hinged to the arm above the yoke.
CARBON HOLDER. G. R. Lean, Cleveland, Ohio, 571,975. Filed May 23, 1896.
ARC LAMP. J. Rae, New York, 572,064. Filed Nov. 26, 1895.
Enclosed arc type.
GLOBE ATTACHMENT FOR ELECTRIC LAMPS. E. Schrantz, St. Louis, Mo., 571,802. Filed Aug. 15, 1896.
Means for attaching a globe to incandescent lamp sockets.
ELECTRIC LIGHT CORD ADJUSTER. G. L. Gulliford, Bement, Ill., 571,761. Filed May 9, 1896.
A spool shaped electric light cord adjuster provided with slots in its heads which receive the cord, while the slack of the cord is wound on the spool.

Miscellaneous:—

ELECTRIC IGNITING DEVICE FOR GAS BURNERS. G. F. Kreiger, Kiel, Germany, 571,769. Filed May 4, 1896.
Details of construction.
GAME APPARATUS. A. W. Fall, Hoboken, N. J., 571,997. Filed Jan. 7, 1896.
Comprises a water receptacle and a float, constituted in part of magnetizable material and a single rotatable magnet pivoted to the under side of the receptacle.
ELECTRIC FAN FOR VENTILATING STREETS OR ALLEYS. V. V. Hedges. Coffeyville, Kan., 572,008. Filed Nov. 13, 1895.
Comprises a motor, a casing for the same, a shaft driven by a motor, fans carried by the shaft, a support upon which the motor casing is revolubly mounted, and means for making and breaking the circuit by the rotation of the motor casing.

Railways and Appliances:—

ELECTRIC STREET OR STATION INDICATOR. H. Alwies, St. Louis, Mo., 571,738. Filed Aug. 10, 1896.
Comprises a web with the names of the stations disposed thereon, mounted upon rollers and means for operating same at predetermined points by current supplied from the main conductor.
ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 571,832. Filed Feb. 17, 1886.
A track conduit system.
ELECTRIC RAIL BOND. G. H. Short, Worcester, Mass., 571,888. Filed April 23, 1896.
MEANS FOR GENERATING ELECTRICITY FROM CAR WHEEL AXLES. M. Moskowitz, Newark, N. J., 571,951. Filed July 19, 1895.
Part of system described in The Electrical Engineer, Nov. 25, 1896.
UNDERGROUND ELECTRIC POWER SYSTEM FOR RAILWAYS. W. L. King, Winston, N. C., 572,013. Filed May 21, 1896.
Details of construction.
TROLLEY FINDER. W. J. Donahue and W. B. Hausman, Philadelphia, Pa., 571,994. Filed Oct. 10,1895.
Consists of a wheel having right and left hand grooves increasing in diameter toward the center and merging with the central groove on diametrically opposite sides of the wheel.
ELECTRIC MOTOR RAILWAY TRUCK. J. A. Brill and G. M. Brill, Philadelphia, Pa., 571,825. Filed June 25, 1888.
The combination with the axle box frame, of a motor sleeved at one end on one of the truck axles, a cross bar extending between the side bars of the frame, and a connection for the free end of the motor to the cross bar.

Regulation:—

SYSTEM OF ALTERNATING CURRENT REGULATION AND DISTRIBUTION. B. G. Lamme, Pittsburg, Pa., 571,836. Filed April 6, 1896.
Comprises an alternating current generator, feeders supplied thereby, a direct-current circuit and a rotary transformer having a single compound wound field magnet and an armature located in the resultant field produced by the compound winding and connected to the alternating current and direct current circuits.
ROTARY TRANSFORMER REGULATION. R. D. Mershon, Pittsburg, Pa., 571,863. Filed April 6, 1896.
Consists in compounding the field of the transformer and establishing a difference of voltage between the same and the generator, which difference decreases as the load upon the direct current side increases.

Switches, Cut-Outs, Etc:—

ELECTRIC SWITCH. J. T. Norton, Boston, Mass., 571,927. Filed Jan. 28, 1896.
A flush push button switch.
ELECTRIC SWITCH. M. Moskowitz, Newark, N. J., 571,952. Filed June 11, 1896.
Adapted for use in circuits between dynamo and storage battery when charging the battery.

Telegraphs:—

TELEGRAPH. L. W. Hildburgh, New York, 571,948. Filed March 5, 1896.
Means to adapt systems employing alternating currents for the simultaneous transmission of two or more messages in the same or opposite directions without the employment of special apparatus.

Telephones:—

APPARATUS FOR MULTIPLE SWITCHBOARDS FOR TELEPHONE EXCHANGES. C. E. Scribner, Chicago, Ill., 571,906. Filed Feb. 7, 1893.

Comprises several pairs of connecting plugs, conductors joining the different members of each pair, branches connecting each of the conductors with one terminal of an operator's telephone, and retardation coils included in the branches.
TELEPHONE. C. E. Scribner, Chicago, Ill., 571,907. Filed Feb. 7, 1893.
Electro-magnetic telephone receiver.
TELEPHONE EXCHANGE SYSTEM. C. E. Scribner, Chicago, Ill., 571,910. Filed Oct. 16, 1894.
Consists of an arrangement of apparatus and circuits for the telephone switchboard adapted for use with either grounded or metallic circuits or with a "mixed system."

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

NEW G. E. PACKED CARD RHEOSTATS.

THE new line of rheostats built by the General Electric Co., and illustrated in the accompanying engravings, are known as packed card rheostats, deriving their name from their method of construction.

To form a unit resistance card a wire ribbon of German silver of definite length and size is wound upon a tube of asbestos formed on a steel mandrel and which, when the mandrel is withdrawn, is flattened and creased in a press to give it the card shape. In building the rheostat any desired number of these unit cards are placed side by side and separated by asbestos. The whole is then clamped by suitable end plates and bolts and forms a resistance section. To increase the radiating capacity of the resistance section iron plates are inserted between cards and project beyond the general surface of the section. The same general structure is followed in all rheostats and motor starting boxes of the packed card type, the cross section and length of the resistance wire or ribbon alone being varied. The use of the flat card allows a very large resistance capacity to be placed in a small space while the creases hold the coils firmly against displacement.

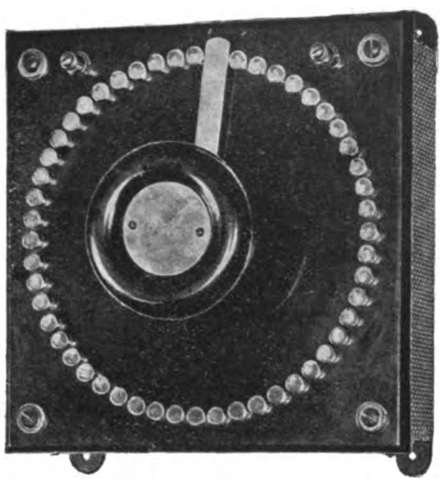


FIG. 1.

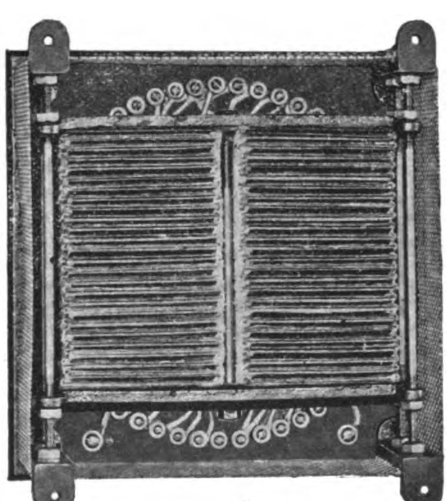

FIG. 2.

The advantages of this method of rheostat construction may be thus summarized. Absence of combustible material, exceedingly large radiating surface for weight and bulk of resistance material, chance of short circuit or similar troubles eliminated by complete insulation of the resistance, easy replacement of damaged cards when necessary, ability of resistance to withstand overloads; it expands and contracts freely, and as the burning of one card only impairs the use of the apparatus until a new one can be inserted, or the old one be short circuited, no overload can destroy the rheostat.

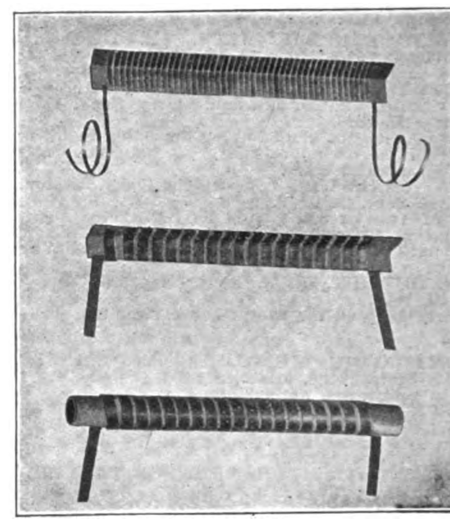

FIG. 3.

The switches used with these rheostats differ with the use to which the device is put. The steps of the field rheostat switches vary in number from 25 to 50—the majority having 50 steps to provide for close regulation—and are mounted on 10x10 inch slate bases. The motor switches, with the exception of the three largest sizes are also mounted on slate bases, the number of steps up to and including 10 horse-power being the same.

The starting rheostats for motors are built with or without automatic release switch, the standard switch being automatic. This automatic release is essential to the successful operation of isolated motors for if the current stops, the circuit is automatically opened and remains open until closed by hand. The motor armature is thus protected against injury by any sudden rush of current, if the supply of current in the mains be suddenly thrown on after having been cut off as sometimes happens with street mains. With the automatic switch the starting resistance is all in as soon as the motor is shut down from any cause.

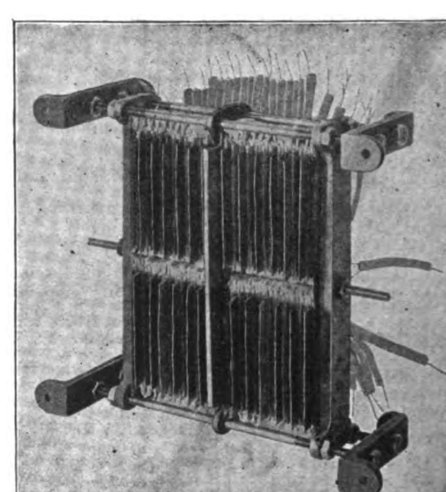

FIG. 4.

The generator field rheostats are constructed to be mounted either in front or behind the switchboard; the motor starting rheostats for the front of the switchboard only. The former are built for 500, 250 and 125 volt circuits, the latter for 110,

Fig. 5.

220 and 500 volt circuits, those for 110 and 220 volts being adapted for use also on 125 and 250 volts.

In the engravings, Fig. 1, shows the standard generator field direct current rheostat, a back view being shown in Fig. 2. Fig. 3 shows the wound tube and pressed card and Fig. 4 the iron plates between the cards. Fig. 5 shows the standard motor wiring direct current rheostat and automatic switch.

THE AMERICAN ELECTRIC HEATING CORPORATION'S FOOT WARMER.

As shown in the illustration, the American Electric Heating Corporation of Boston have just put on the market an electric foot warmer and foot rest combined, of such substantial form and apparent usefulness as to command special consideration from the public. The device generally is of cast iron, finished in black enamel. The heat is applied directly to the under side of the top plate by the enamel process, making

New Electric Foot Warmer.

a durable device that will stand any sort of treatment that it is likely to be subjected to. As it requires but 50 watts it may be attached to any lamp socket by means of the usual plug and cord (with which it is equipped) and can be placed in any desired location about the room or office. It is not inconvenient to move about as it weighs less than 10 pounds, and never reaches a temperature, under any conditions, that would be uncomfortable to handle. In about ten minutes after the current is turned on the foot plate is quite warm and it reaches a maximum temperature of about 145° F. in from 15 to 20 minutes. The working temperature of the device is such that in a very few minutes after placing the feet on it, one experiences a comfortable feeling of warmth, which condition does not change with continued use. In other words, the maximum temperature has been determined by careful experiment as being that at which one can comfortably keep the feet on continuously without producing the disagreeable effect incident to holding them over a register too long. The device is such that it can be used the year round as a foot rest and will add much to the comfort of those sitting continuously at a desk.

It is clear that the foot warmer will have a wide application. There are thousands of people whose occupation confines them in small booths, cashier's offices, ticket offices and the like, through the winter months where it is impractical to have a stove on account of the limited size of the compartment. There are many stenographers, bookkeepers and others who suffer (by reason of impaired circulation) for the want of such an appliance, in rooms which, to one in full vigor, are perfectly comfortable. Invalids and elderly people will not be forced to make others uncomfortable around them with a high temperature in the room if they may keep their feet warm. In cold weather the temperature of a room betwen the surface of the floor and an elevation of a few feet above it is, in most buildings, many degrees different, and it is a difficult thing to so regulate the temperature that one is not suffering from drafts and cold feet or, on the other hand, suffocating from excessive temperature. This device certainly will prove a boon to many.

HOUSTON AND KENNELLY'S "ELECTRICAL ENGINEERING LEAFLETS."

Attention is directed to the important announcement made in our advertising pages, with regard to the Houston & Kennelly Electrical Engineering Leaflets. As is well known, these Leaflets are issued in three series, Elementary, Intermediate and Advanced, meeting the educational necessities of three grades of students. Each book is a handsome volume of about 300 pages, cloth bound, interspersed with numerous cuts, chiefly plain diagrams made specially. The Leaflets have been a great success and have been used everywhere, not only by individuals, but by classes, schools, Y. M. C. A.'s and colleges; often by men in lighting stations and on electric railways. Hitherto the price has been $2 per volume, but henceforth it will only be $1.50, for which price a copy will be sent postage free to any address. All three books in the series can be heartily recommended, either for reading singly, or for successive study as the subject becomes better understood.

CONSOLIDATION OF GAS AND EDISON INTERESTS IN SAN FRANCISCO CO.

A recent special meeting of the stockholders of the Gas Light Company was held, at which the Board of Directors was authorized to organize the San Francisco Gas and Electric Company, upon the terms and conditions agreed upon with the Edison people, and the capital stock of the old company was reduced from $10,000,000, divided into 100,000 shares of the par value of $100 each, to $300,000, divided into 100,000 shares, of par value of $3 each. In entering the new combination the Gas Company stockholders turn over to it all of its street mains and other property used in the manufacture of the illuminant material for $10,000,000 of the stock of the gas and electric corporation. This includes its plants at Howard and Fifth streets, at the Portero and at North Beach, with the site and new office building on Post street, above Powell. There is other property, however, belonging to the Gas Company's stockholders, estimated to be valued at $300,000, which is not included in the deal, the liquidation of which requires that the old corporation shall continue in existence. Among it is land on Second and King streets, the lot on the corner of First and Natoma, and mortgages held on its property adjoining that was sold some months ago. To close these up the San Francisco Gas Light Company will continue under its reduced capitalization until the stock holders are all paid, when it will disincorporate. The Edison Light and Power Company has already agreed to join the combination, it receiving stock to the amount of $2,750,000 and its outstanding bonds, to the amount of $800,000 with interest thereon, making $1,066,000, being guaranteed by stock to that sum in addition, or $3,816,000 in all. The capital stock of the San Francisco Gas and Electric Company will be $20,000,000.

Charles Wirt, 1028 Filbert street, Philadelphia, has appointed as Southern agents, the Electric Supply and Construction Company, Savannah, Ga., who will carry a full stock of Wirt brushes and supply the Southern trade.

CHICAGO FUSE WIRE & MFG. CO.

The Chicago Fuse Wire and Manufacturing Company announce in another column a new catalogue of their well known line of Tested Fuse Wire and Links. Mr. W. R. Goodman, manager of this company, who has been identified with this line for the past eight years, has, by constant and vigorous handling of the business, brought the goods into general use throughout the United States, and to a considerable extent in foreign countries. They further announce that the present outlook for business is very favorable.

THE CALLENDER AUTOMATIC TELEPHONE EXCHANGE SYSTEM.

The ingenious automatic telephone exchange system of Mr. Romaine Callender, illustrated in The Electrical Engineer some time ago, has been acquired by the Callender Telephone Exchange Co., Ltd., of Brantford, Canada; capital, $100,000.

Franchises have been obtained in Troy, O., and Piqua, O. Construction has already begun in Troy, and a complete set of apparatus will soon be shipped to that city from Brantford. The work at Piqua will proceed shortly after Christmas. It is said that all the Bell subscribers at Troy will go over to the Callender exchange, and 80 per cent. of those at Piqua. The Callender Co., will shortly move its headquarters to Ohio.

"THE LIVING AGE."

The importance of "The Living Age" to every American reader, as the freshest and best compilation of gleanings from the field of British periodical literature has been long recognized. Founded by E. Littell in 1844, it has never ceased to occupy a prominent place among the foremost magazines of the day. In pursuance of the same general plan adopted by its founder, and to give the best the world can offer, the publishers have arranged for the introduction of certain "New Features" so widening its scope as to embrace translations of noteworthy articles from the leading publications of France, Germany, Spain, Italy and other continental countries, many of which contain matter of great interest and value to the American reader, yet which, for obvious reasons, are absolutely beyond his reach but for the timely help of this delightful medium. In addition a monthly Supplement will be given, containing three departments devoted to American literature. Its prospectus more fully describes these new features, the first of which appears in a November issue.

A year ago the price was reduced from $8 to $6 a year. This reduction brings the Magazine within the reach of a much wider class, and certainly at this price, with these improvements, it is at once the cheapest and the best literary weekly in existence. In no other way can its equivalent be obtained for less than many times its cost. Reduced clubbing rates with other periodicals offer still greater inducements, and to new subscribers remitting now for the year 1897, the intervening numbers of 1896 will be sent gratis. The "Living Age" Co., Boston, are the publishers. "The Living Age" and The Electrical Engineer will be sent to any address at the club rate of $8.50 per year.

ADVERTISERS' HINTS.

C. A. ECK, 157 Oraton street, Newark, N. J., advertises direct current dynamos and motors of high grade in sizes ranging from ⅛ to 10 horse power. They are described very fully in a catalogue which will be sent on request.

THE CENTRAL ELECTRIC CO., Chicago, offer a complete line of X-ray apparatus.

G. A. FREI CO., 17 Bromfield, street, Boston, Mass., illustrate in their "ad." this issue a static X-ray machine for all kinds of X-ray work and demonstrations in static electricity.

THE CAMPBELL AND ZELL COMPANY, Havermeyer building, New York, will send to those desiring it a book entitled "How to Generate Steam Economically," which should be of interest to all steam users.

WM. TAYLOR, 203 Broadway, New York, has considerable to say regarding the points of superiority of Packard transformers.

SCHWEDTLE & SIEBERT, 35 Fairfield avenue, Bridgeport, Conn., manufacture steel stamps, stencils, burning brands, seals, checks, badges, etc.

MR. ARTHUR A. KENT, of the Kent Electric Manufacturing Company, Worcester, Mass., was a visitor to New York City last week attending to business in connection with the small induction motors for fan work, etc., which they are now placing on the market.

NEW YORK NOTES.

WM. TAYLOR, 203 Broadway, has been appointed Eastern sales agent for the well-known Packard transformers.

THE MATHIESON ALKALI COMPANY, of New York City, are to build a large factory at Niagara Falls, N. Y., in which to manufacture caustic soda, by electrical process.

MR. E. P. HOPKINS, electrical expert of J. B. Colt & Co., has been awarded the John Scott medal of the Franklin Institute for improvements in the arc light for the purposes of projection.

IDEAL ENGINES.—The Harrisburg Foundry and Machine Works are building a large engine for the official residence of the president of Brazil, for electric lighting. The engine will be direct connected to a General Electric generator.

"FROM THE MAIL." This is the title of a very clever and pretty little book issued by the Vacuum Oil Co., to help the sale of their lubricating oils for machinery. It opens with a portrait of Mr. Edison and a testimonial from him. There are many others from all over the world, printed in the languages of the respective countries of origin. Those for this country represent many of the leading concerns and apply to engines, dynamos, etc. The book is one of the artistic productions of the Orr Press of Bartlett & Co.

MR. C. B. STERLING has become vice-president of the Standard Electric Lamp and Novelty Company, 248 West Twenty-third street, and has started on a long western trip to deal with the many inquiries and requests for agencies that have reached the concern. Mr. Sterling is well known from his connection with the Central Electric Heating Company, and other electrical enterprises. The field for miniature lamps, Crookes tubes and other specialties made by the company is large, and with the brightening prospects of general trade is likely to be larger.

NEW ENGLAND NOTES.

THE CONNECTICUT TELEPHONE AND ELECTRIC CO., of Meriden, Conn., have issued a very neat and tasteful catalogue of their new telephonic apparatus. It is their second catalogue and exemplifies steady growth and improvement in all branches. The first part of the pamphlet is devoted to transmitters, of which a large variety are shown, and then come receivers in equal profusion, all with details and prices for the different styles. Other portions of the book describe switchboards, batteries, switches, lightning arresters, etc., and numerous testimonials are quoted. The concern will be glad to receive inquiries as to private lines or exchanges.

THE UNION TRACTION COMPANY, of Rutherford, N. J., are to erect a new power house and car barn. The entire contract for this work has been let to the Berlin Iron Bridge Company, of East Berlin, Conn. The buildings will be of brick with steel frame work, and the plant when completed will be up to date in all respects. The car barn is 97x100 feet, adjoining which will be the offices, store rooms and repair shop. The engine room is 50x65 feet, and the boiler room 40x65 feet. The roofs are supported on steel trusses, and the covering is to be corrugated iron throughout. The roof of the engine house is lined with the Berlin Company's patent anti-condensation fireproof roof lining, which always gives proper protection against fire and condensation, and is in fact the only lining which has stood the test in use for roofs of this nature.

WESTERN NOTES.

THE BARNEY & SMITH CAR CO., of Dayton, Ohio, have completed and delivered to the B. & O., 10 combination baggage and passenger cars. These cars are of the latest design, being equipped with gas, heated by steam, and painted blue, and are 60 feet in length.

MR. E. M. HARRISON, in the Harrison International Telephone Company suits, has filed a long answer in regard to the allegations of fraud and wrecking, and claiming that he was induced by the misrepresentations of his associates on the board of directors to participate in their irregular actions.

SOUTHERN NOTES.

MR. T. H. RUSSOM has been appointed General Car Foreman of the Mt. Clare shops, B. & O., vice Mr. C. H. Williams, resigned.

THE CAMPBELL & ZELL CO., the well-known boiler-making concern of Baltimore, was put in the hands of a receiver last week, owing to the difficulty of collections, etc. The assets are put at $432,000 and liabilities at only $163,000. The large business is being carried on as usual.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXII. DECEMBER 9, 1896. No. 449.

ELECTRIC LIGHTING.

THE NEW ELECTRIC LIGHT AND RAILWAY POWER STATION OF THE EDISON ELECTRIC ILLUMINATING CO. OF PATERSON, N. J.

INTRODUCTORY.

LINKED with the history of Paterson, N. J., is the name of Alexander Hamilton, who realized immediately after the Revolution that manufacturing industries were necessary to utilize our raw products, and supply those manufactured articles which had been previously shipped to us by England. He selected Paterson as a natural manufacturing center, it having the advantages of considerable water power and close proximity to the metropolis of the country. Under his guidance the water power was improved and made valuable; the factories soon outgrew the capacity of the water power, and the city of Paterson became dotted with factories of all kinds, the silk industry taking the lead. There are over one hundred silk mills in Paterson now, and it has been called "the Lyons of America." Among the other prominent products at the present time are locomotives, structural iron and flax thread.

Early in the art Paterson was supplied by electric light from the Hochhausen system. In the year 1888 this system was bought by the Paterson Electric Light Company, who installed the Thomson-Houston arc and series system for municipal lighting, and also a duplicate of the Edison three-wire system for power and domestic lighting.

FIG. 3.—A CORNER OF THE BUSINESS OFFICES.

Later in the same year the Edison Electric Illuminating Company, of Paterson, were formed in competition with the Paterson Electric Light Company, and they installed a three-wire plant, operating under the Edison patents. They located their station on Paterson street, near Market, and it was constructed according to the best engineering practice of that date, and has always proved a very profitable investment. To compare the station of 1888 with the station of 1896 has a historical value and shows great progress in every department of equipment and construction of lighting and power stations.

A fierce competition was carried on between these two companies, which resulted in the Edison Company absorbing its rival in April, 1890. Since that time both stations have been operated by the Edison Electric Illuminating Company, using the old Paterson Electric Light Company's station only as an arc light plant, and the Edison Company's as a combined lighting and power plant.

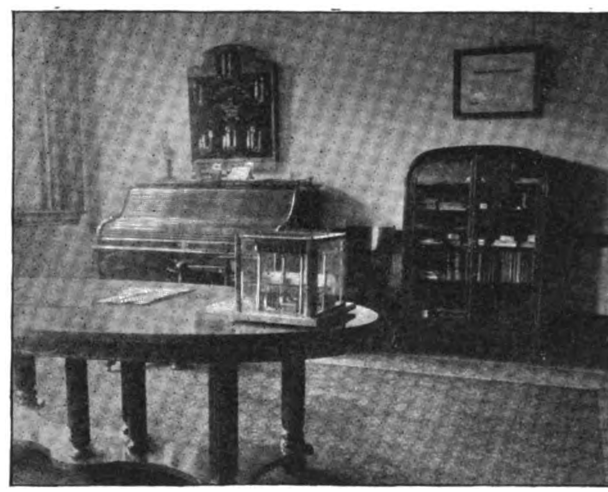

FIG. 4.—OFFICE OF THE GENERAL MANAGER.

With the advent of electric railways, the Edison Company made a bid and succeeded in securing all contracts to supply, with power, the railways in Paterson and its vicinity. Under conservative management, the business increased so rapidly that at a meeting of directors, in the latter part of the year 1894, it was decided that Mr. William Brock, general manager of the Edison Electric Illuminating Company, of Paterson, make a report on the best method of meeting the increasing demand for power and light, which was taxing the two stations to their utmost capacity. As a result of this report, it was decided on account of abundant water for condensing, and because the site was nearer the center of distribution of the Paterson system, to locate the plant near the Passaic River, and on one of the raceways from the Passaic Falls. The location secured was at the corner of Van Houten and Prospect streets, where one of the largest plants of its kind in the United States is now located.

THE STATION BUILDING.

Our engraving, Fig. 1, shows an exterior view of the new station building, which is of selected Haverstraw brick, with blue stone trimmings. The total length of this building is 384 feet and the width 92 feet. Fig. 2 shows the plan of the station and raceways around the building, as well as the location of the engines, dynamos and boilers. This arrangement was laid out by Mr. William Brock, and the building details were developed with the assistance of Mr. J. W. Ferguson, of Paterson, N. J., who was also the contractor for the entire structure. All the brick is laid in cement mortar. The contract for this building was let on August 1, 1895, and it was completed and turned over to the owners on February 1,

1896, which was remarkably quick time, considering the stability and character of the structure. It required over 80,000 bricks to be laid a day, in order to complete this building within the specified time.

In the ground plan, Fig. 2, it will be noticed that the executive building occupies the front of the structure. It is 70x55 feet, with three stories and basement, and with a wire tower 20 feet square and 81 feet high. The offices, meter-room, storeroom and exhibition room, are on the first floor, while the general repair shop and storerooms, as well as the armature winding department, occupy the two upper stories, which are reached by an electric elevator.

The main entrance to the building is through the wire tower. The walls of this tower are lined with wiring ducts, which are concealed by being overlaid by fancy tiling, and reach from the cellar to the top story, where the distribution boards and lightning arresters for the overhead system are placed .The stairs winding around this tower give another method of reaching the upper floors. A general view of the offices is given in Fig. 3, and that of the general manager's office in Fig. 4. Of course, the main interest in a structure of this kind centers in the engine room. The whole back of the office and storeroom section is solid masonry, the only opening between the engine room and the office building being a door on the office room floor. This forms a perfect fire wall, and divides the semi-combustible structure from the non-combustible structure, there being no combustible material used in the whole engine room or boiler room, or in any of the appliances, except the window frames, and such precautions have been taken in this part of the structure that it is very doubtful whether the company are not justified in saving their insurance premium.

THE FUEL SUPPLY AND UTILIZATION.

The station has been built from the investor's standpoint, and every means that could be adopted to improve the operation and reduce the cost of production of current has been carefully studied and adopted, if it warranted the investment; consequently, in describing those methods and appliances which have been adopted, it is more logical to start at the beginning of the process and note the interesting and special points in this plant, as they occur in the process of current generation.

The coal used is low grade "buckwheat," and it is delivered in the conveyor hopper, Fig. 5, across the raceways from the boiler room, shown in section Fig. 6, and conveyed to a 1,200 ton bin in the top of the boiler room. The conveyor, put in by the Hunt Conveyor Company, continues its course and passes underneath the boiler room floor, where the ashes from the boiler are delivered automatically to the conveyor, and carried to an elevated ash bin, from which the carts are loaded by a chute. The coal on leaving the storage bin passes into a weighing bucket, there being one for each boiler, where it is retained and weighed before being discharged on the boiler room floor, and where it is for the first and last time handled manually when being thrown on the grate. These boilers are provided with a shaking grate, and the ashpit slopes away toward the conveyors so that there is no cleaning to be done underneath the firebox.

Enough coal may be uselessly passed between the coal pile and boiler by careless firing, which, if saved, would pay a div-

FIG. 1.—THE NEW LIGHTING AND RAILWAY POWER STATION OF THE EDISON ELECTRIC ILLUMINATING CO., PATERSON, N. J.

idend, and hence special attention was devoted to this part of the plant. On opening these boiler doors, an ideal fire about an inch and a half thick, is seen, with a four-inch streamer flame uniformly distributed over the whole grate surface, the natural draught being used without choking, and the resultant gases from combustion being transparent.

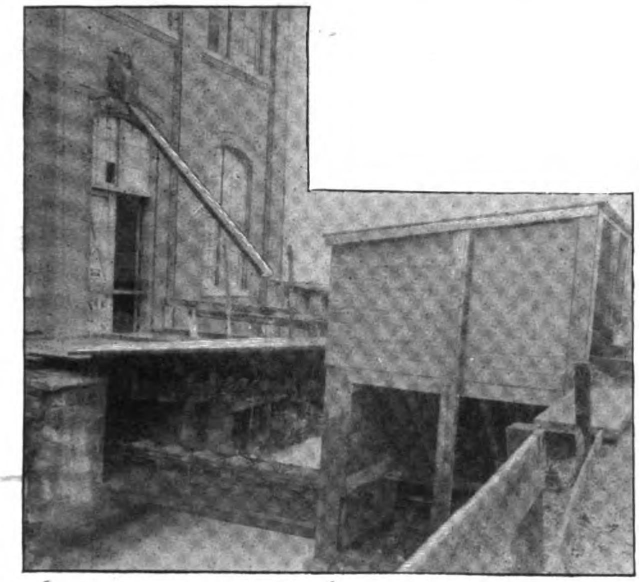

FIG. 5.—COAL HOPPER AND CONVEYOR.

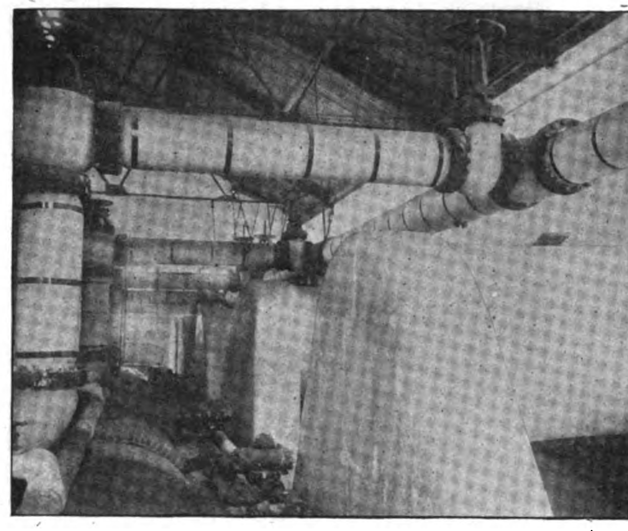

FIG. 8.—STACK CONNECTIONS AND BREECHINGS.

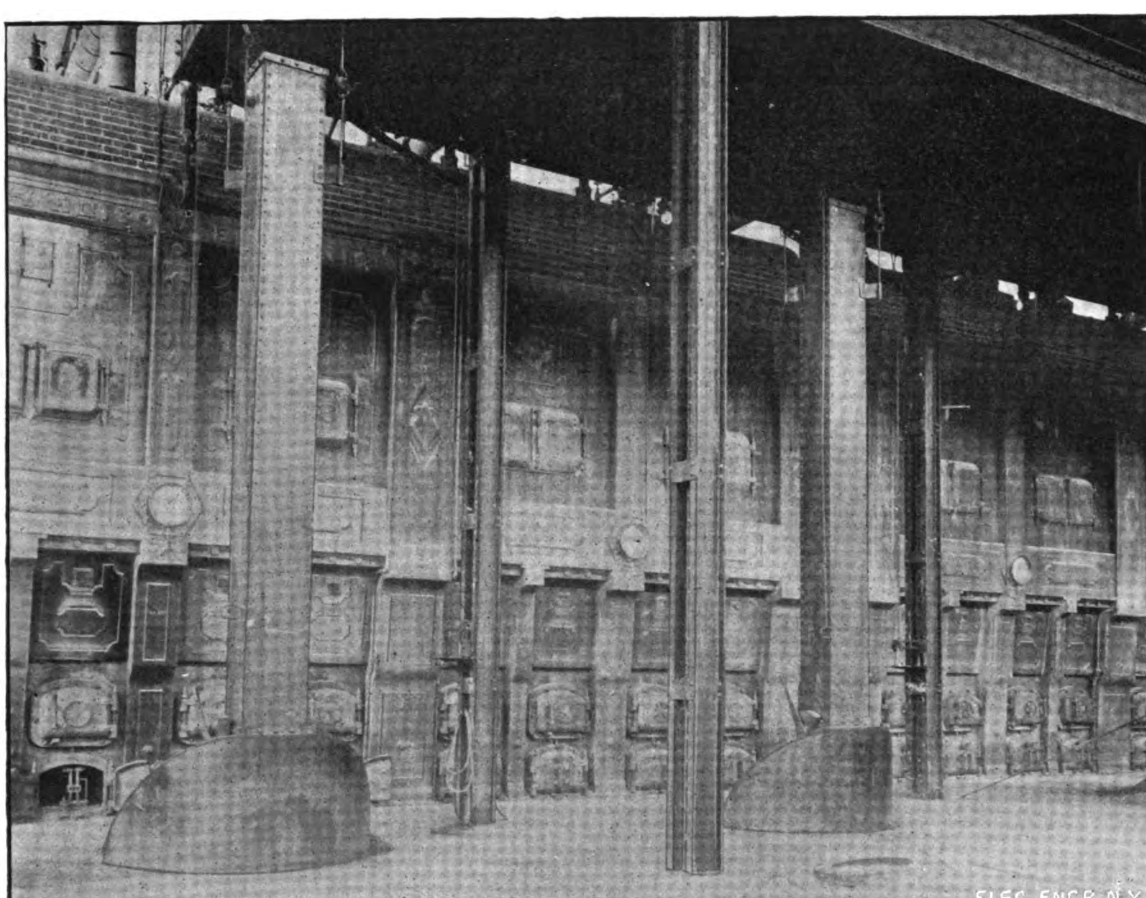

FIG. 7.—VIEW OF STIRLING BOILERS, EDISON ELECTRIC ILLUMINATING CO., PATERSON, N. J.

THE BOILERS AND SMOKE STACK.

The boilers are of the Stirling type, shown in Fig. 4, and of 500 horse-power each, run at 150 pounds pressure. The present battery consists of six boilers, and the future extensions provide for a duplicate battery. The gases, after all the heat that can be is extracted from them on passing around the boiler tubes, are again passed through a Green economizer, where the hot gases circulate through a system of tubes and heat the feed water, and are again reduced in temperature before reaching the foot of the stack. The storage of energy in the feed water allows the boilers to respond readily to a sudden call for steam. If the gases are still too hot, they are impeded in their course up the chimney by means of an automatic damper regulator.

The heat radiated from the stack connections and breech-

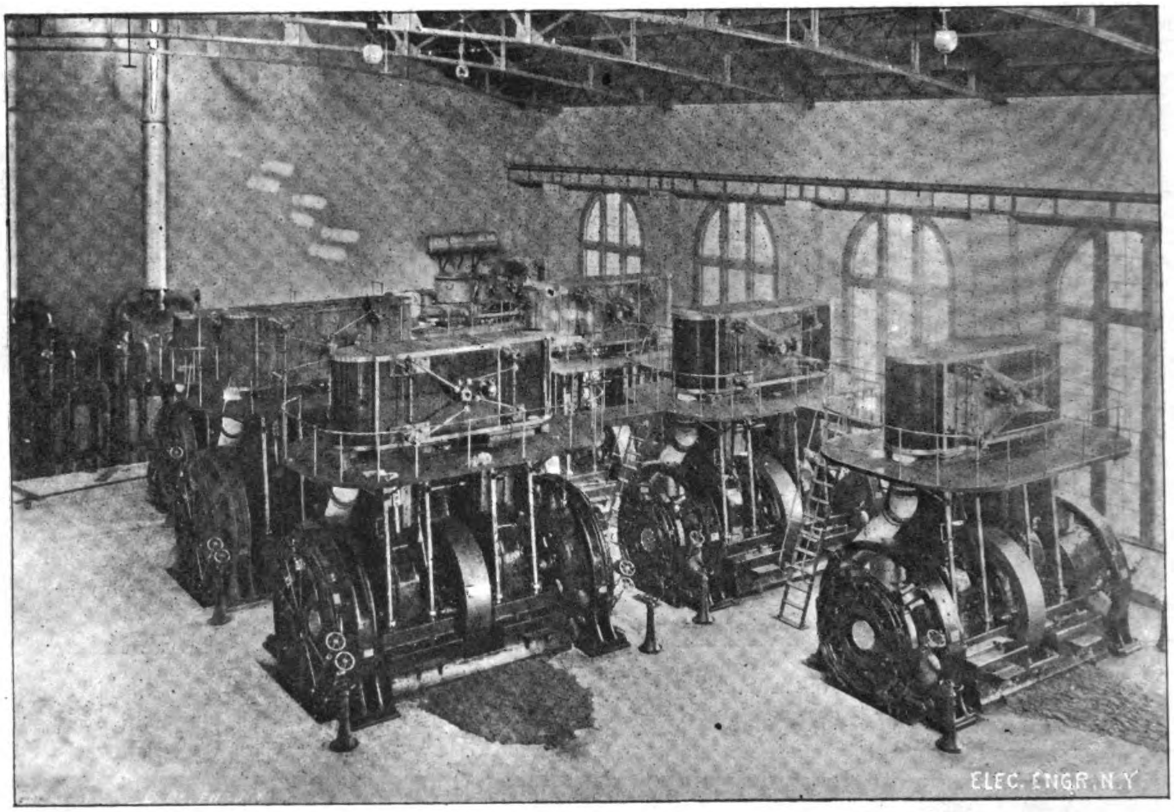

Fig. 10.—Edison Electric Illuminating Co., Paterson, N. J. View of Engines and Generators from Controlling Gallery.

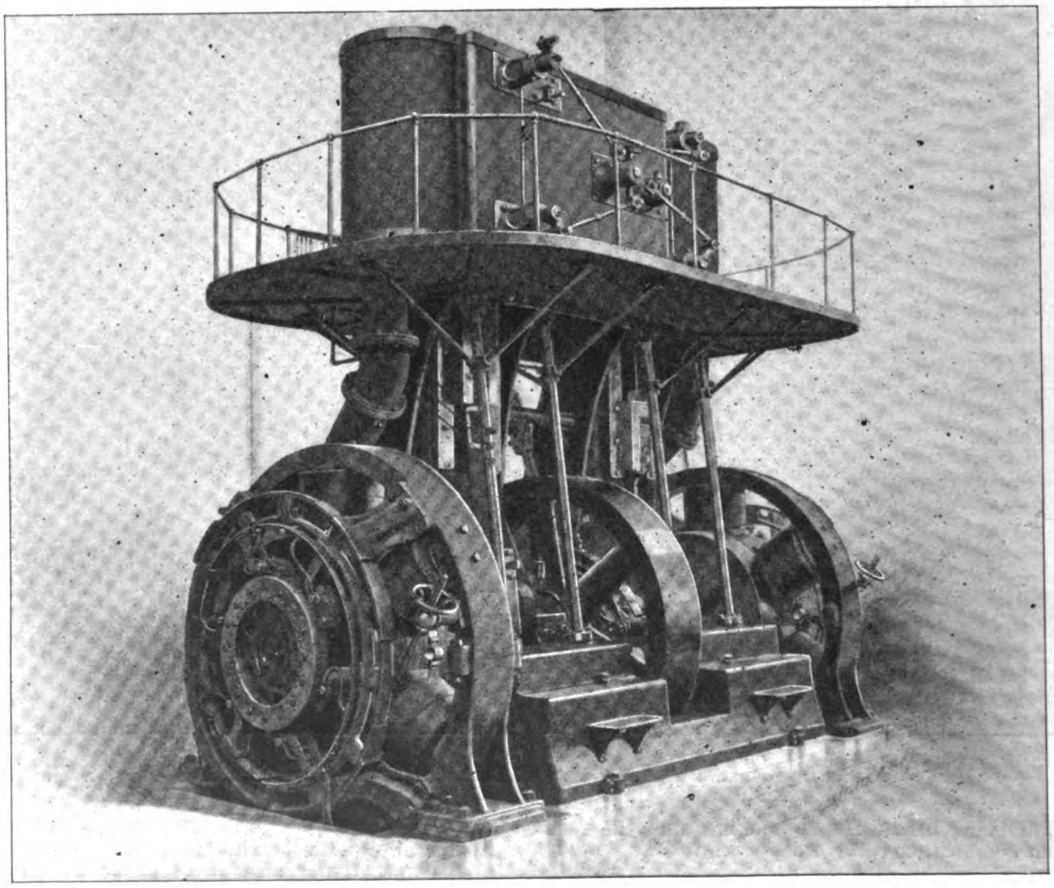

ig. 10a. —Ball & Wood Compound Condensing Engine, Driving General Electric Railway Generator, Paterson Edison Station.

ings is largely saved by having them covered with a fireproof covering, as shown in Fig. 8, their treatment being the same as that used for steam piping. Heat is again saved here, which more than pays the interest on the investment. The

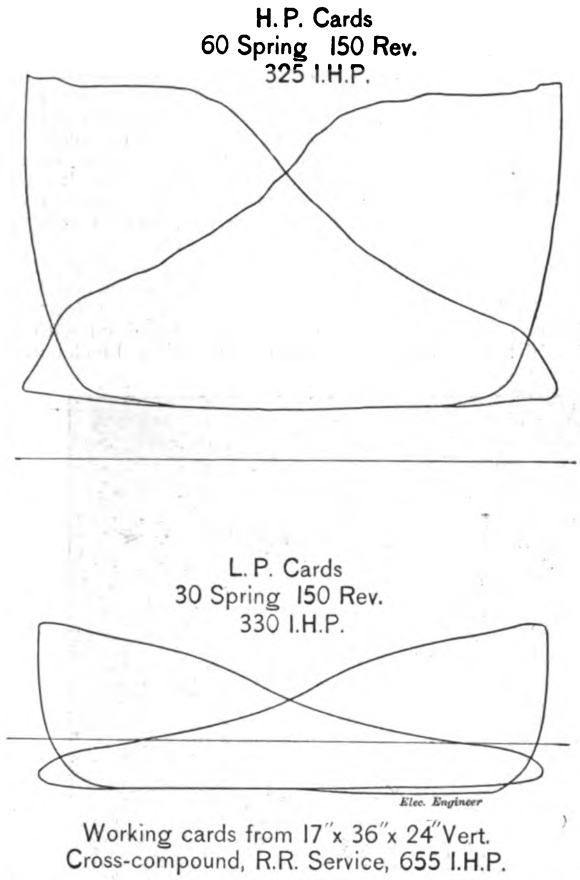

FIG. 11.—INDICATOR CARD FROM BALL & WOOD COMPOUND CONDENSING ENGINE.

water supplied to the boiler is taken from the hot well by two Worthington pumps and forced through the Greene economizer, thus reaching the boiler at a temperature of 250 degrees Fahrenheit. Every boiler is provided with a hot water meter, which has a by-pass around it, so as to be readily taken out of service for recalibration, and there is a main hot water meter to again check these individual boiler meters. All drips and entrained steam are also metered before being delivered to the boiler by traps.

As the performance of the boiler is the relation between the water it evaporates and the coal it burns, this relation can be determined every day for each boiler by reading the water meters and taking the weight of coal burned. These results excite considerable interest and also competition between the different firemen, resulting in better firing and less coal consumption for the output.

The dumping grates under the boilers are of the "Common-Sense" type, furnished by Messrs. Hine & Robertson, who also supplied the steam engine indicators and planimeters.

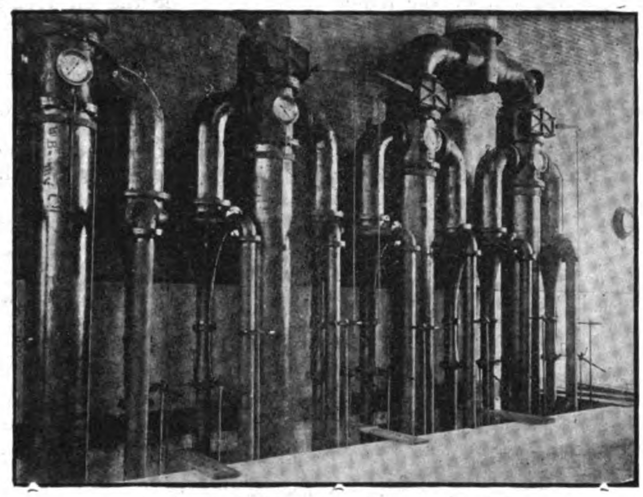

FIG. 12.—THE BULKLEY CONDENSERS.

To increase the draught beyond the natural draught of the chimney, which is now 1 inch of water, a blower is used, consisting of an engine directly connected to a rotary blower, furnished by the Kensington Engine Works. Besides the general economy of this arrangement, an artificial draught for an electric light station has the additional value that it enables the firemen to steam quickly for a rapidly increasing load, which is often caused by cloudy or foggy weather, and in this way brings on suddenly a heavy lighting load. At such times the blower can be used for forcing the draught with great advantage, as at these times the atmospheric conditions are usually extremely unfavorable to a natural draught. All boilers are provided with Henderson's angle check valve, which only allows the boiler to connect to the main pipe when the pressure is up to the main pressure, and which closes off any boiler if the pressure in it falls rapidly.

The smokestack is the highest but one in the State of New Jersey, and its construction deserves special attention. The

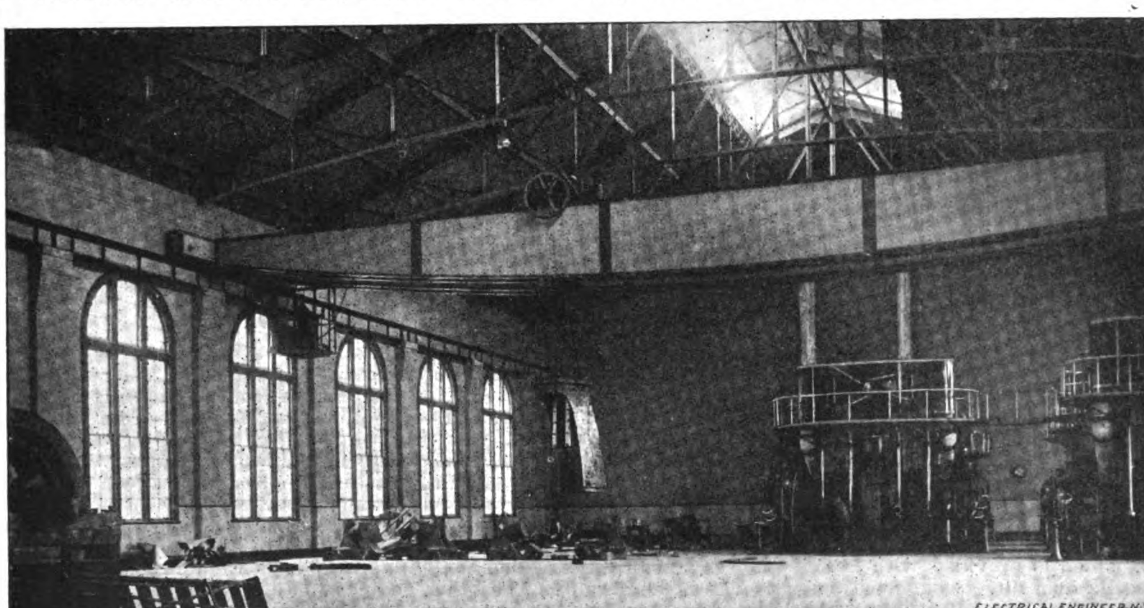

FIG. 14.—20-TON CRANE, 92-FOOT SPAN, IN PATERSON EDISON STATION.

height from the foundation to the top is 235 feet, with a 10-foot flue, and its diameter at the base is 22 feet; the other dimensions will be found in the detail drawing, Fig. 9. The foundation on which it is built is piling driven into the earth and over this is laid 5 feet of concrete. The chimney is double walled for 130 feet 9 inches, and at every 15 feet a wrought iron ring is set into the brickwork, in this way bonding the chimney together. There were 900,000 bricks used in the construction of this chimney, and an electric hoist was used during its construction, no outside staging whatever being employed. The material was hoisted on the interior of the chimney.

In passing out of the boiler room, we enter the oil room, where the oil circulating system terminates from all engines and dynamos in the building. Here the oil is filtered before being forced, by means of compressed air, up to the gravity tank, where it is again circulated through the oiling system. The rest of this room is provided with lockers, lavatory and bath rooms for the employés.

The boiler room being 15 feet 6 inches lower than the engine room, it gives a natural drip system to all steam piping, which is of wrought iron, screwed and expanded into cast iron flanges. These flanges are bolted together and have as a packing corrugated metallic gaskets. The piping is protected from radiation by the H. W. Johns Company's fire covering. The steam valves were furnished by the Eaton, Cole & Burnham Company.

THE ENGINE EQUIPMENT.

Above this room on the engine room level is located the machine shop, which is provided with lathes, planers and drills, each having its own direct connected motors. The machinery has been so selected that all fittings and repairs necessary for the plant can be made here.

The engine room is 92x206 feet, the walls are 31 feet from the floor to truss, and the total capacity is 15,000 horse-power.

All the engines are of the vertical marine type, Fig. 10, built by the Ball & Wood Co., of New York. The engine equipment now installed is as follows: Four 600 horse-power compound condensing engines for railway work, with 140 pounds of steam pressure and 150 revolutions. The high pressure cylinder of each engine is 17 inches in diameter, the low pressure cylinder 36 inches in diameter, and the length of stroke 24 inches. Each engine is capable of delivering 625 horse-power without vacuum. The valves of these engines are of the Corliss type, double ported. Their location forms one of tne novel features in the engine, and reduces the idle steam clearance to 3 per cent. The steam exhaust valves are at the top and bottom of the cylinder instead of at the sides, and the valve can be raised from its seat by any undue pressure which may be caused by water being entrained in the cylinder, no strain being thrown on the engines from this cause. The valves are actuated from a wrist plate, which is connected by means of link and eccentrics to the governor. This latter is of the inertia type, in which the eccentric is part of the inertia mass distributed in the fly-wheel. The forces which actuate the eccentric are large and are extremely sensitive to the slightest changes of speed. All moving surfaces are oiled by a continuous gravity system, and oil is delivered to the crank pin by a centrifugal oiling device. The four pillow blocks on which the main shaft rests are provided with movable babbitt liners, and the two center pillow blocks are provided with adjustable wedges, and their adjustment can be effected while the engine is in operation if necessary. Fig. 10 A gives a view of the engine room from the regulating gallery.

The card of the engine, Fig. 11, shows very little wire drawing, and the steam in passing between the high and low pressure cylinders is superheated by means of live steam coils before entering the low pressure cylinder. The steam from the low pressure cylinder is exhausted into the condenser, which maintains a 26-inch vacuum.

The other engines in this plant are of the same type, and there are two 600 horse-power engines, identical in dimensions and speed with the above, for the low tension three-wire system, and one 315 horse-power compound condensing engine running at 180 revolutions with 140 pounds steam pressure.

For the arc lighting system two 700 horse-power compound condensing engines running at 130 revolutions per minute, with 26-inch vacuum, are employed. The high pressure cylinder is 20 inches in diameter, the low pressure cylinder 41 inches and the length of stroke 24 inches. This engine connects by

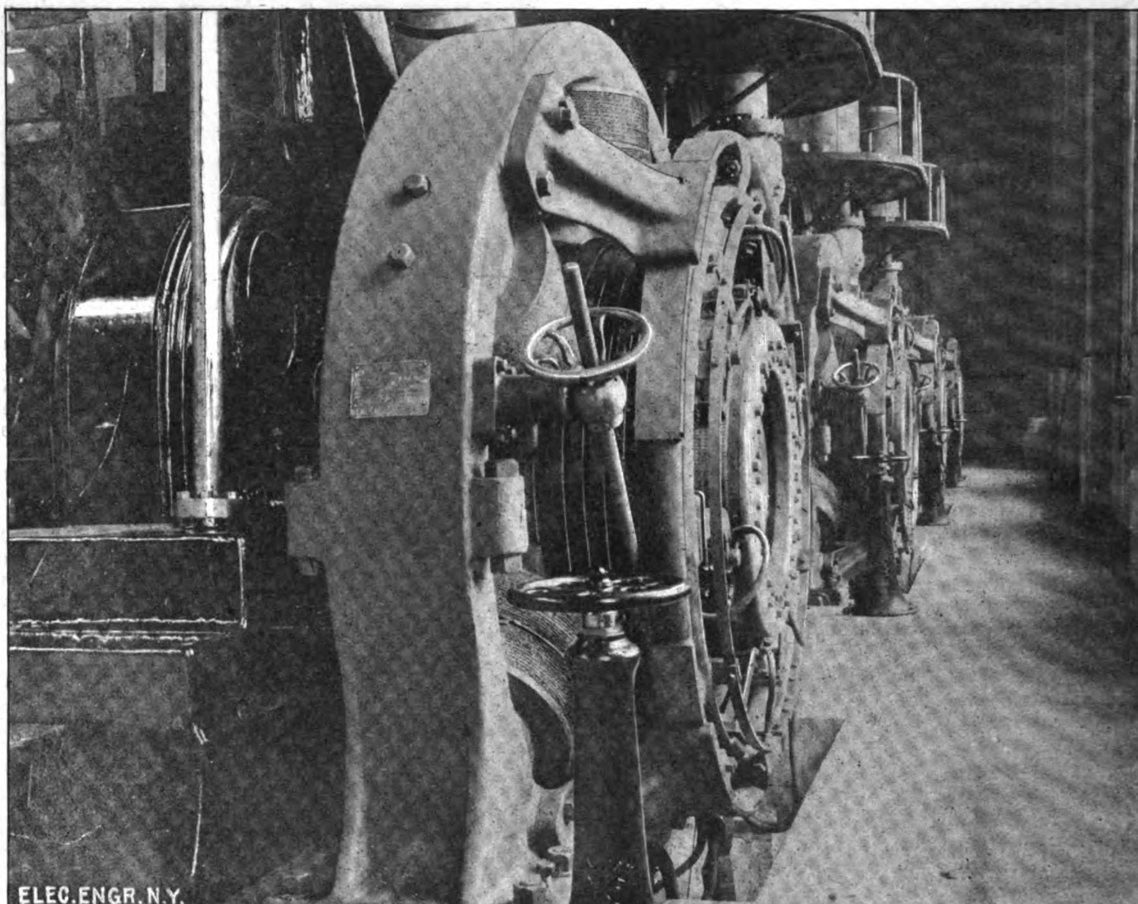

FIG. 15.—VIEW OF RAILWAY GENERATORS, PATERSON EDISON STATION.

means of a rope drive to the quill for the arc lighting machines. All the cylinders in these engines are provided with steam jackets and are guaranteed to deliver an indicated horse-power hour, for 15½ pounds of dry steam. These engines are designed to give their maximum efficiency at 80 per cent. of their full load, and it will be noticed from the load curves that this will be their average duty. The steam traps were furnished by the Albany Steam Trap Company.

THE CONDENSING APPARATUS.

Each pair of engines exhaust through an 18-inch pipe into two Bulkley injector condensers, of which there are now eight in all, located about 34 feet above the water level in the hot well, as shown in Fig. 12. The condensing water flows through a 30-inch main, under a head of about 22 feet, a separate vertical pipe leading to each condenser. After the vacuum is started by a pipe from the city water pressure, the water is syphoned over into the condensers, entering them in a thin circular film. The exhaust steam thus enters a hollow cone of moving water, and in condensing, imparts to it a velocity that enables it to expel the air and vapor through the contracted neck of the condenser, into the discharge pipe below. A vacuum of 27 inches or more is thus maintained at no cost, as the water right goes with the property. Should the water supply from the raceway fail, the condensers will then be supplied from the Passaic River by direct connected centrifugal pumps.

ENGINE ROOM CONSTRUCTION AND ACCESSORIES.

The floor of this station presents novel features of construction. It provides for both a fireproof and an insulated structure. Fig. 13 shows the cross-section of this floor with the ribs of cement moulded underneath the flooring. Inserted before the cement is tamped in position are two twisted 1-in. iron rods, one in the upper part of the rib or web, and one in the lower part. Moulds of wood were used to form the cement floor, which, after the cement had set, were removed. The floor was subjected to a test after two weeks, with a load of 400 pounds per square foot, and it showed no deflection or cracking. This floor was laid by Jacob Sharp, of Paterson, N. J., and on being treated with ozokerite, will be a fair insulator, so that the attendant will be protected from shocks while adjusting brushes.

All assembling of engines and dynamos and handling of material was done by a 92-foot 20-ton Shaw crane, shown in Fig. 14, which can handle material in any part of the engine room or switchboard gallery. Two McClelland combined oil purifiers and storage reservoirs are in use, furnished by the McClelland Oil Purifier Co.

THE RAILWAY AND INCANDESCENT GENERATORS.

Each engine is directly coupled to two six-pole, 225 kilowatt, 150 revolutions, 500-volt generators for railway work, built by the General Electric Company, having a total output of 820 amperes and 550 volts. Fig. 15 shows a perspective view of these dynamos on one side of the engines. There are four sets now installed, with a total output of 3,280 amperes. The armatures are overhung, and each pair is supported by four bearings having ample wearing surface, so that there will be no appreciable wear, nor does the shaft show any deflection. It is interesting to note here that the ultimate output of this plant would have been cut down 20 per cent. if outboard bearings had been necessary. Fig 10 A shows the unit complete.

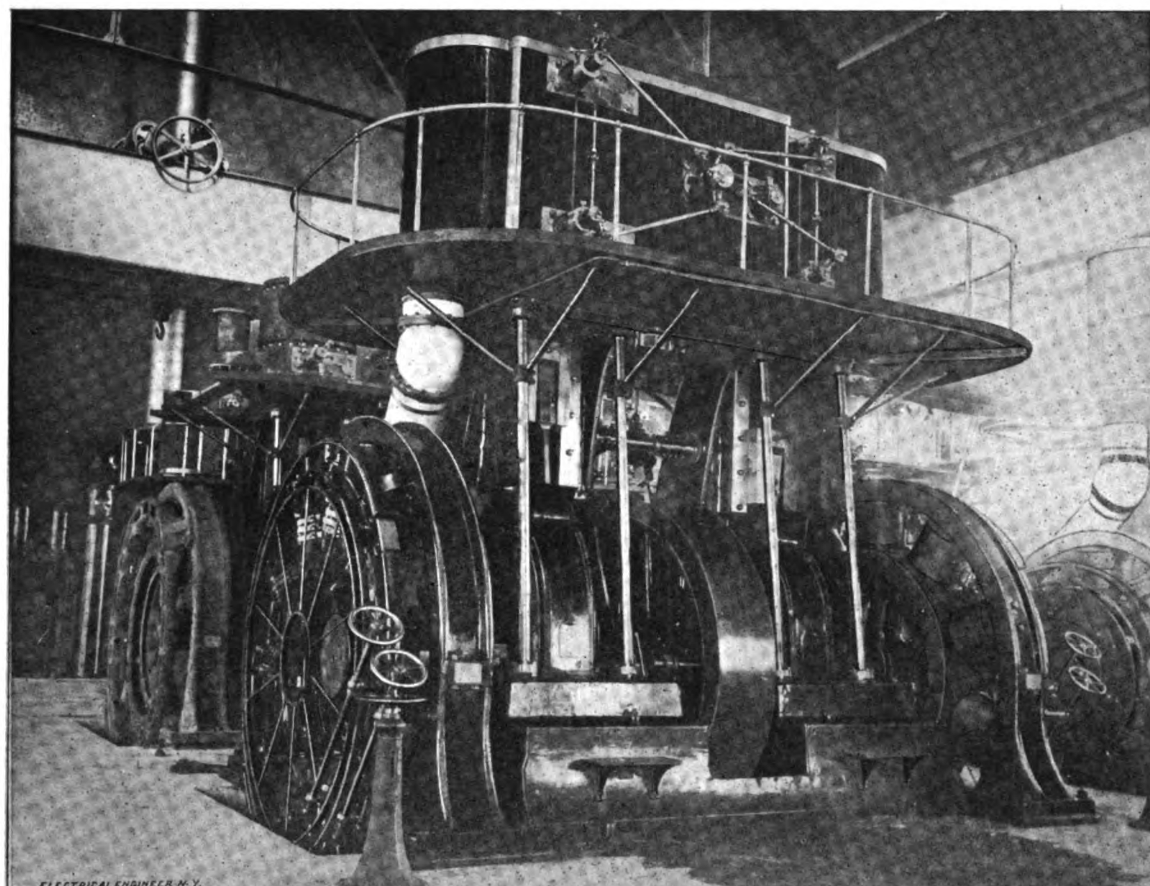

FIG 16.—GENERAL ELECTRIC INCANDESCENT GENERATOR UNITS, PATERSON EDISON STATION.

The armature of these generators is of the slotted, ventilated type, with developed surface winding, and with radial carbon brushes, which are all mounted to a brush holder rig which can be adjusted by screw and handwheel. These generators are 10 per cent. over-compound.

Four of the incandescent dynamos are of the ten-pole, 200-kilowatt, 150-revolution, General Electric type, Fig. 16, overhung and connected to the same style of engines as those driving the railway generators. The armatures of these machines have a smooth body and have a two-path winding. The side of the armature is used as a commutator, and gauze brushes bear directly on the armature winding. There are two units provided with two 200-kilowatt generators each, and one unit directly connected with two 100-kilowatt generators, with a total output of 6,660 amperes.

THE ARC GENERATORS.

The arc light plant, located on the west side of the building,

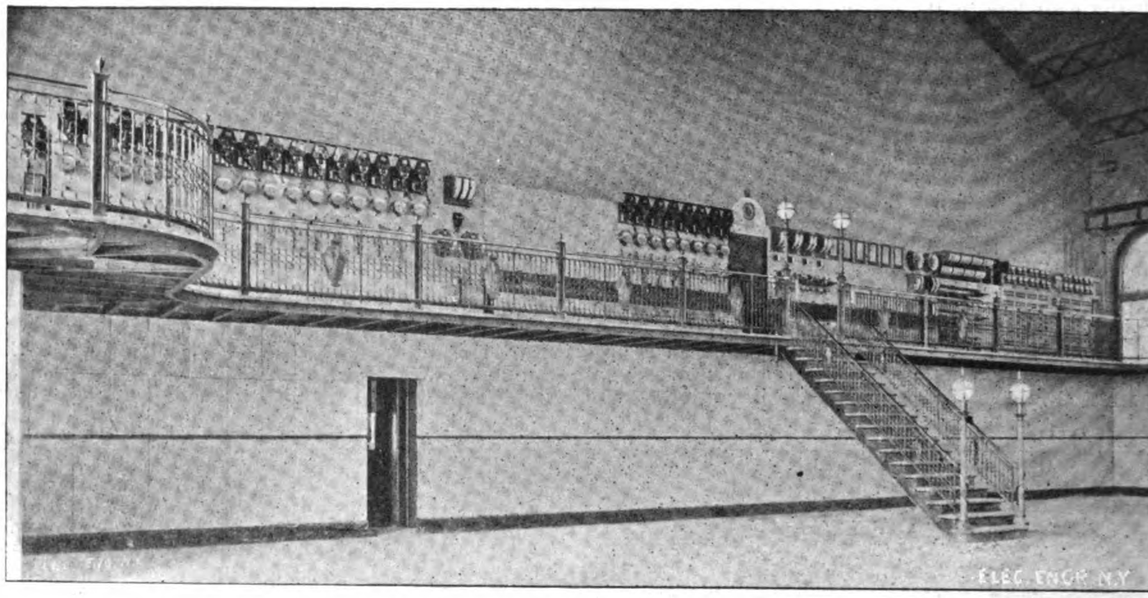

FIG. 17.—THE SWITCHBOARD GALLERY, PATERSON EDISON STATION.

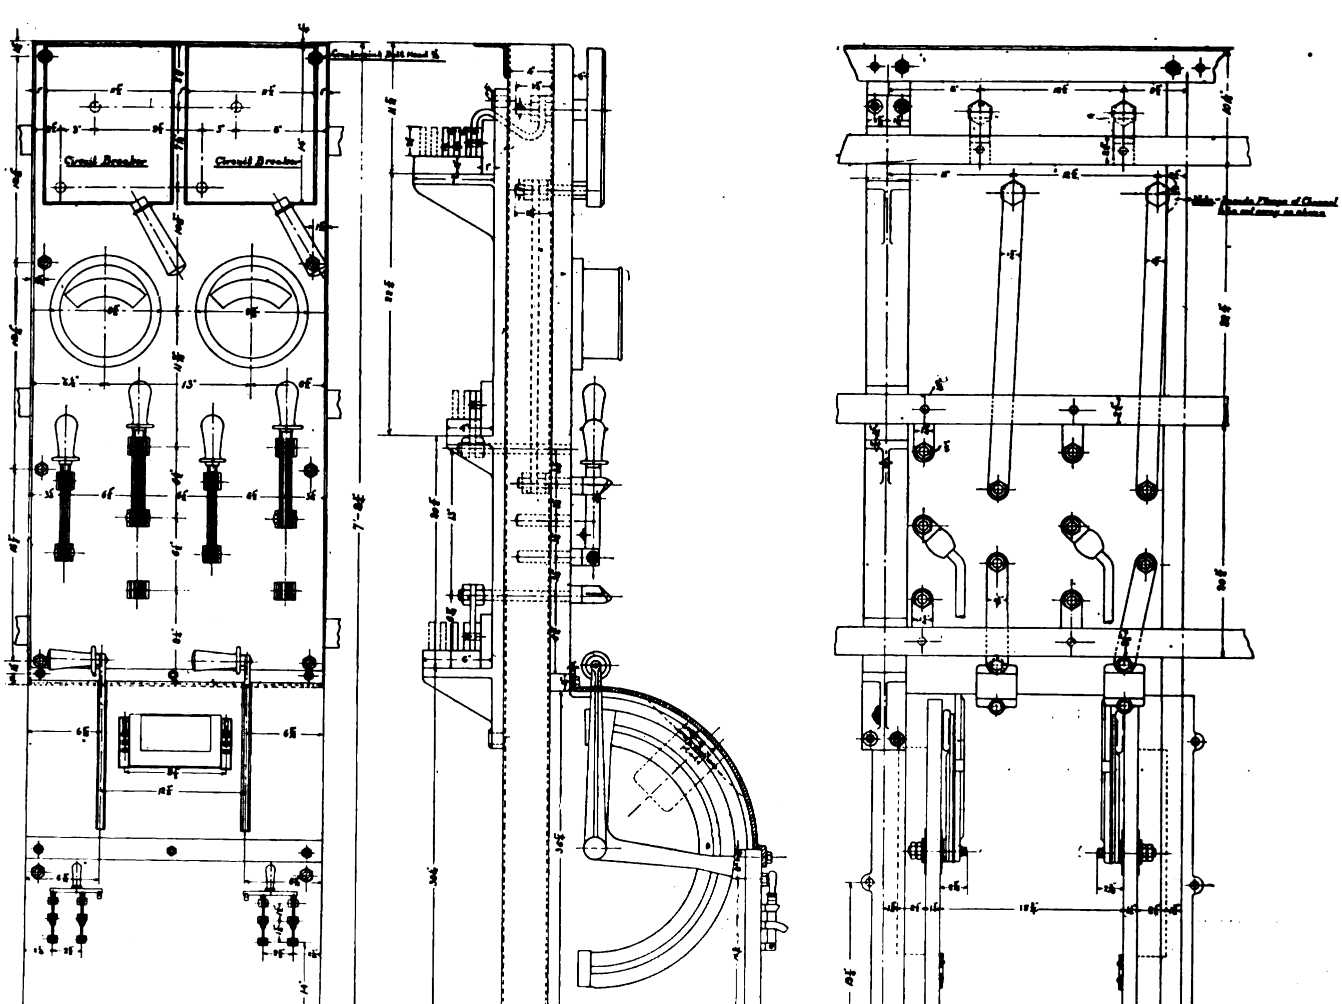

FIG. 18.—DYNAMO RAILWAY SWITCHBOARD, PATERSON EDISON STATION. FRONT, SIDE AND REAR VIEWS.

Designed by Messrs. Herrick and Burke, Consulting Engineers.

consists of nineteen 50-arc light machines and four 125-arc light machines. These are of the Brush and Thomson-Houston type, and are connected by belting to a continuous quill by Hunter friction clutches. This quill passes through the center of a hollow shaft, to which is secured the driven pulley from the engine. The driving gear from the engine is

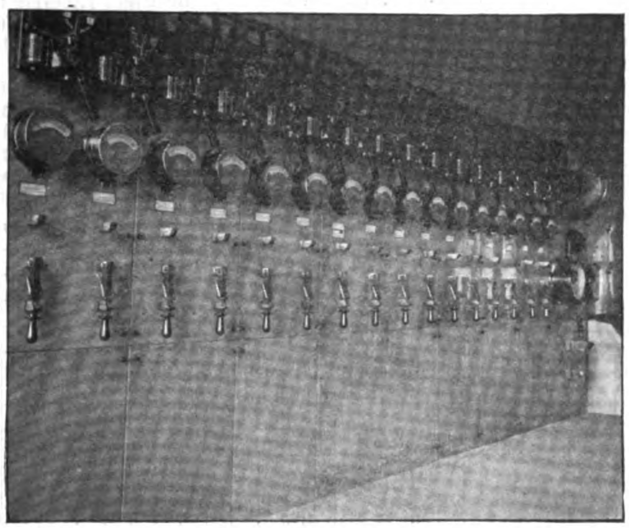

FIG. 19.—THE RAILWAY FEEDER SWITCHBOARD.

rope, provided with the Hoadley transmission system, which consists of a continuous rope, several turns of which are carried around the helical groove of the driven pulley, in order to increase the adhesion between the pulley and rope, and a slack loop is held under the tension by means of a tension pulley, and the same pulley also passes the rope back to the beginning of the driving pulley spiral. The driven pulley from the engine is also provided with a friction clutch, so that any dynamo can be run from any engine.

The compressor used for the oil circulation system is also used for blowing out dynamo armatures, hose and nozzle be-

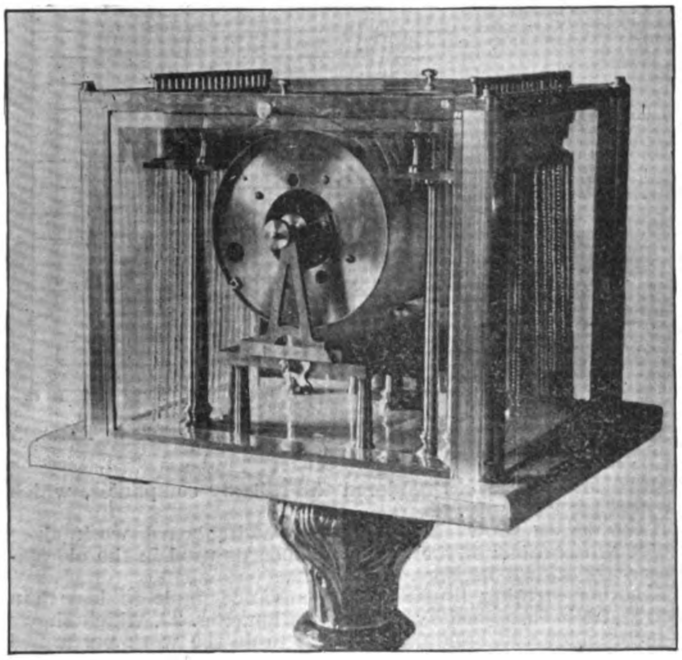

FIG. 20.—TIME RECORDER FOR RAILWAY FEEDERS.

ing used for the purpose of reaching all the parts of the armature, and after the dynamo has been shut down the attendant is required to clean all armatures by the air blast. All conductors from the generators are carried underneath the floor by means of split porcelain insulators secured to iron work under the floor, and these conductors are insulated with fireproof covering, so as not to be a conductor of fire or to increase the fire hazard. They pass up behind the wall under the gallery to the switchboard.

THE SWITCHING AND REGULATING APPARATUS.

The switchboard occupies a gallery 92 feet long, shown in Fig. 17, extending across the north end of the building and 10 feet above the engine room floor, and is reached by a stairway, so that the switchboard attendant has a view of all dynamos and engines in the plant. The supporting structure under the switchboard is iron framework covered with artificial marble. The beams for the gallery floor have a footing in the wall, and the platform in front of the switchboard is overhung 5 feet, forming a cantilever structure; there is 4 feet of space behind the board, giving ample space for all conductors and passageway. The gallery floor is of selected slate, the ironwork supporting the switchboard marble is all insulated from contact with the iron structure of the gallery, being built up on marble, and the iron frameworks of the different switchboards are again insulated from each other. The switchboard itself is of Ellis pink Tennessee marble, quarried so that all veining matches, furnished by the Evans Marble Co.

On the right hand of the doorway is the three-wire incandescent and power board, and to the right of this is the arc light board. The switchboard at the left of the door is for the railway service.

The different appliances for this board were designed for and purchased by the company, and the whole switchboard was assembled and erected by its employés, under the supervision of Messrs. Herrick and Burke.

Fig. 18 shows one dynamo railway board for a pair of dy-

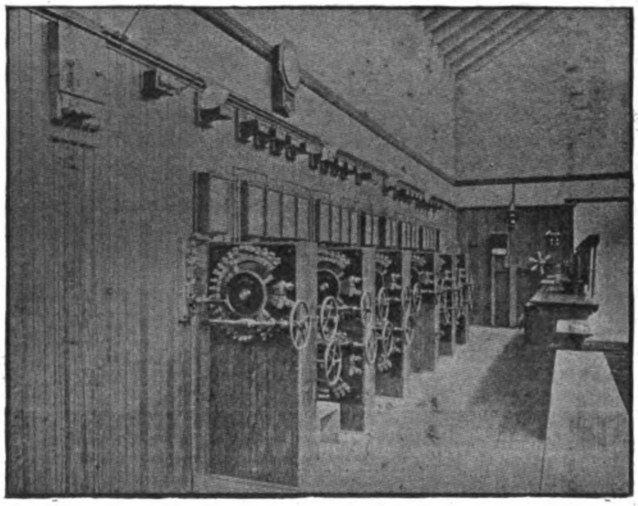

FIG. 21.—1888 INCANDESCENT SWITCHBOARD, PATERSON EDISON STATION.

namos. At the bottom of this board are the field switches which are double-pole and connected to a lamp bank, so that the fields are discharged through a lamp bank on withdrawing the switch. This switch also interlocks with the regulator so that it cannot be pulled out unless the regulator is at the lowest limit, and all the field regulating resistance is in series with the field and the voltage of the dynamos as low as possible. The regulator is of the quadrant type, on which there are four rows of staggered steps, and 80 changes of resistance are made in moving through 45 degrees, the current and potential rising as the regulator handle is raised.

The dynamo switches are of a recently designed snap switch type, and the positive, or the one leading to the trolley, is double throw, so that the system can be operated either at two potentials or two different railway companies can be operated independently of each other, if necessary. The negative switch is single throw and the equalizer is not brought to the switchboard.

Each dynamo is provided with a dynamo galvanometer, which is located on the dynamo regulator cover, with its pilot switch, which indicates which way the main dynamo switch is to be thrown when the dynamo potential is the same as bus, and each dynamo is independent of all others. The above appliances were designed by the electrical engineers for this plant, and were made by the General Incandescent Arc Light Company.

The amperemeters are of the Weston round dial type, having an oxidized copper finish, which is the finish of all the instruments and appliances on this board. Above the ammeters of

each dynamo is located a circuit breaker, which is of the General Electric Company's magnetic blow-out type. The current from these dynamos passes along the back of the board through bus bars, which are supported on marble insulators, and before it reaches the feeder board, the main negative current passes through a shunt, which gives the total ampere

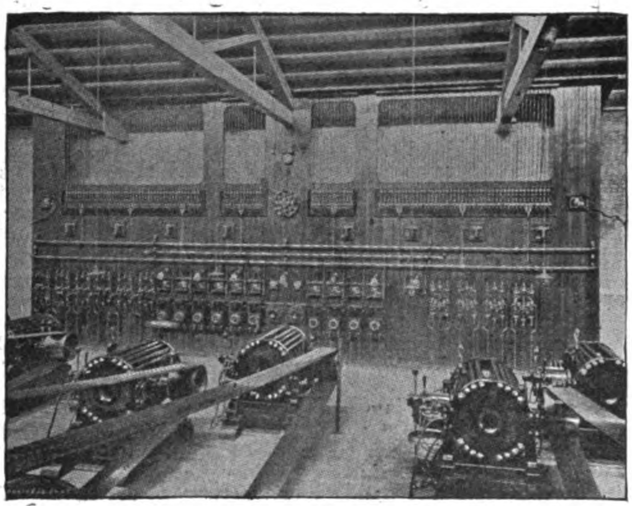

FIG. 22.—1888 ARC SWITCHBOARD, PATERSON EDISON STATION.

reading and also passes through a main 6,000 ampere snap switch, which controls sixty-three miles of road operated by this board. This current is carried off to the ground feeders and connections. The high and low positive both pass through Thomson recording wattmeters and are carried to the feeder board.

There are 82 feeders which cover a territory of 31 square miles, and operate different railroad systems, having a total of 120 cars in operation. Each pair of feeders, which feed into a continuous trolley section, is provided also with magnetic circuit breaker and double throw switch, so that its potential can be either raised or separated from the others in case of trouble. Fig. 19 shows this feeder board.

The incandescent three-wire board is located to the right of the stairway, and is of the same general design as the railway board, having the field switches at the bottom and quadrant regulators above these field switches. The two dynamo switches, the right being positive and the left being negative, are double throw of 2,000 amperes each, so that the machines can be thrown on either high or low potential, and above these are located the dynamo galvanometers and double pole galvanometer switch. Above these again are the edgewise dynamo ampere meters, the width of the panel being 16 inches.

FIG. 23.—SPACE OCCUPIED BY 400 H. P. IN OLD PATERSON EDISON STATION.

with a capacity of 400 kilowatt. The total output of this board is 1,000 kilowatt, or 6,660 amperes. The current is carried along the bus bars at the back of this board and passes through the pressure panel on which are located the main wattmeters, for high and low positive and negative buses, the main amperemeters, and the main voltmeters. It is also provided with a pressure switch by which the pressure of any feeder can be compared with the standard feeder. The current is then distributed to the feeder board and through edgewise ammeters to the distribution system. The arc light board is located on the extreme right and is provided for 32 feeders and 32 dynamos, and is of the well known Brush type. The ammeters are of the General Electric Company's new arc ammeter type; the voltmeter reads to 6,000 volts, and the pressure switch is of special design, built by the Ideal Electric Co. All feeders and circuits are carried out on the wall back of the switchboard through the cellar, under the floor of the office building, to the underground and overhead systems.

In furnishing power to the railway systems, it is very important to know what kind of service has been rendered, and for this purpose the instrument shown in Fig. 20 has been devised by Mr. Brock and constructed by Mr. M. E. Sanger, of New York, and which indicates when any feeder is open, also the length of time it was open, thus keeping an exact

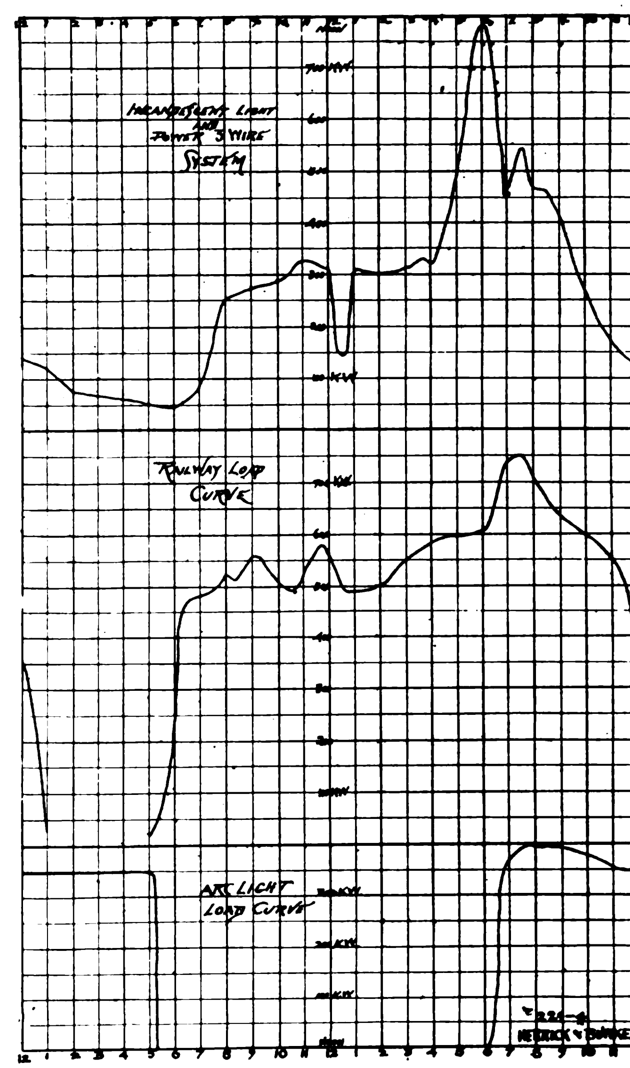

FIG. 24.—LOAD CURVES OF ARC, INCANDESCENT AND RAILWAY SERVICE.

record of the services rendered the railway companies, which is filed for reference.

In order to show the advance in switchboard work since 1888, illustrations of the two switchboards used in the old stations are shown in Figs. 21 and 22.

Another striking illustration of advance made in less than ten years is furnished by the illustration, Fig. 23, which shows four engines and dynamos required to do the work performed by one of the small units illustrated in Fig. 10.

THE ECONOMY EFFECTED.

This station took its load from the other two stations without a moment's interruption of any service, and the improvement in the coal item alone will be 2.8 pounds of coal per kilowatt hour, against 6.9 pounds of coal in the old incandescent station, and 4.3 pounds of coal in the old arc light station. One switchboard attendant can handle the three different systems, and by combining forces in the new station 45 per cent. of labor is saved in the current production. The output of the

three-wire plant can be increased to 25 per cent. with the same drop on feeders on account of the more favorable position of the new station.

The load curves of each of these systems is shown in Fig. 24, and the combined load curves are given in Fig. 25. The load factor for the total plant for October was 53 per cent., and it will be noticed how these three loads combine to bring the steam plant in condition for maximum all day efficiency.

There are a few feeders in the outlying districts which cannot be supplied at the proper potential from the high bus during the lighting hours. Two dynamos of 50 kilowatt each are connected to the quill of the arc light system, and these are run for these feeders. After 12 o'clock midnight the incandescent load falls off, so that these dynamos can carry the whole incandescent load, and the incandescent plant is shut down from midnight till morning hours, when the load commences to rise again.

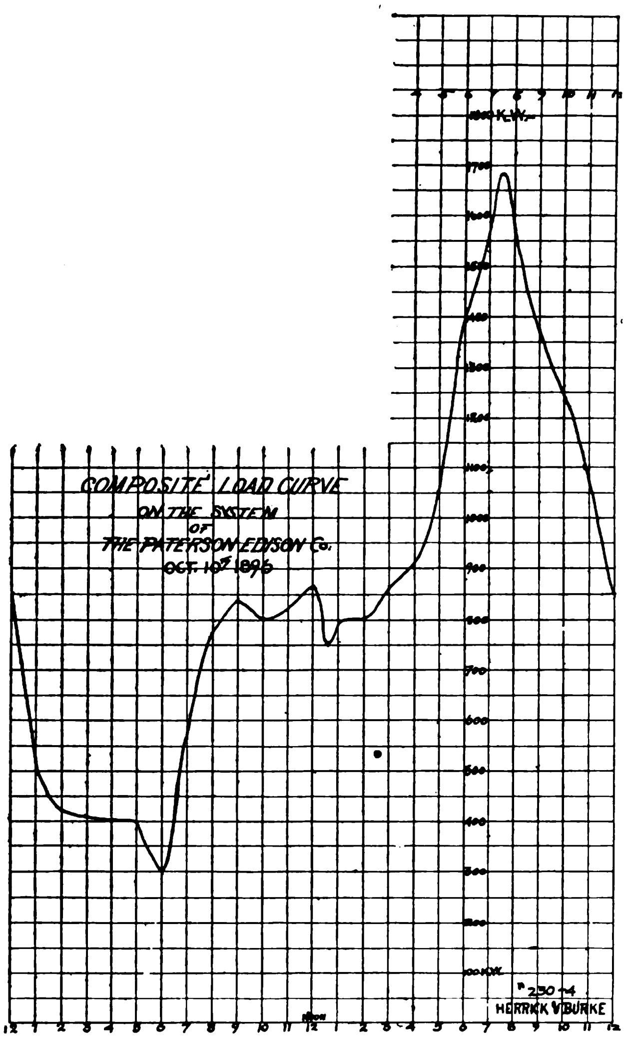

FIG. 25.—LOAD CURVE OF COMBINED SERVICES.

The load on this station is divided up as shown by the load curves. The method of charging for the current is by car miles for the railway, by the Edison chemical meter for the three-wire incandescent and power, and by contract for the arc light. The maximum load in kilowatts for October was 780 kilowatt incandescent, 750 kilowatt railway, and 400 kilowatt arc light, and as the population of Paterson is 100,000, this gives an output of 19 watts per capita.

The officers of the company are: William T. Ryle, president, and the financier of the company; William Strange, vice-president; Arthur Ryle, treasurer, and William M. Brock, secretary and general manager, to whom great credit is due for the conception and erection of this plant, assisted by Mr. J. W. Ferguson, builder and general contractor, and Messrs. Herrick and Burke, consulting and designing electrical engineers.

CICERO, ILL.—The town of Cicero, a suburb of Chicago, proposes to have an electric light plant of its own to illuminate Oak Park and the western part. Plans and specifications from four different companies estimate a cost of $25,000.

INTERCHANGEABLE ELECTRIC SIGNS.

BY THEODORE WATERS.

IT is a fact which must have forcibly struck every electrical man, that the use of electrical effects for advertising purposes, has become very much extended of late. But it may not be generally realized that the manufacture of special electrical advertising devices has grown until it has reached the dignity of a distinct department. It will be found upon investigation, however, that a number of firms have been organ-

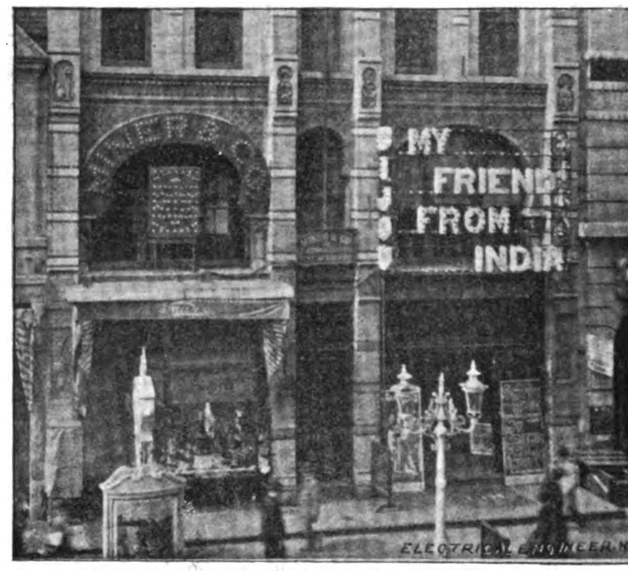

FIG. 1.—ILLUMINATED LETTER SIGNS.

ized with the definite purpose of manufacturing this class of goods. It is indeed a niche which must sooner or later have been filled, for nothing could more fully suit the requirements of the advertising agent than various combinations of electric lamps for the purpose of attracting and holding the attention of the all too fickle public. Upon the general background of night the most brilliant and bizarre effects have been obtained and it does not seem at the present time as though any other agent is soon likely to supersede the electric current in this direction.

The newest feature of the business is the number and variety of interchangeable signs now in use in various places. By

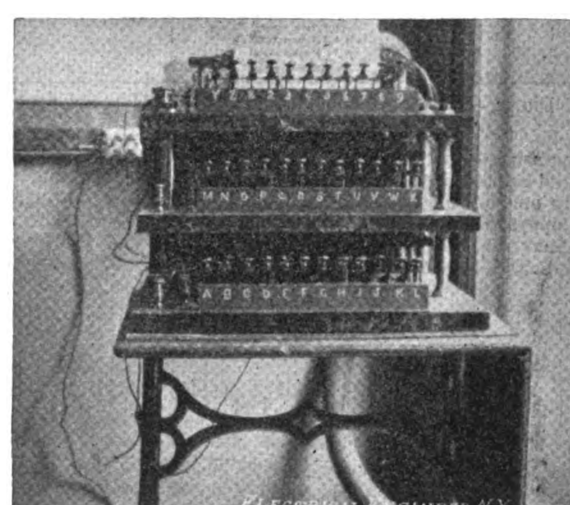

FIG. 2.—KEYBOARD FOR ILLUMINATED LETTER SIGN.

interchangeable signs are meant those devices on which the lettering may be changed at the will of an operator, so that names, mottoes, catch phrases, etc., may be spelled off for the delectation of the onlooker. Some of these devices are very ingenious in arrangement and construction and the var-

iety of their form is sufficiently great to warrant them being collected and described.

Interchangeable or movable letter signs may be divided into two groups. One group comprises those boards on which only

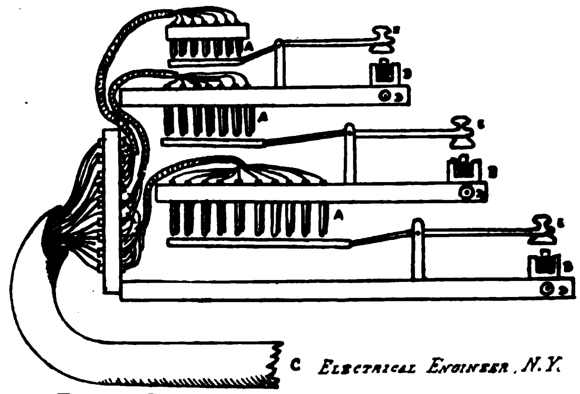

FIG. 3.—DIAGRAM OF KEYBOARD CONSTRUCTION.

one letter at a time can be shown. The other group includes those on which a whole word or sentence may be made visible. Each has its advantage from the advertiser's point of view. It is claimed for the one that the story is instantly told and no time is wasted; it is claimed for the other that the sense of

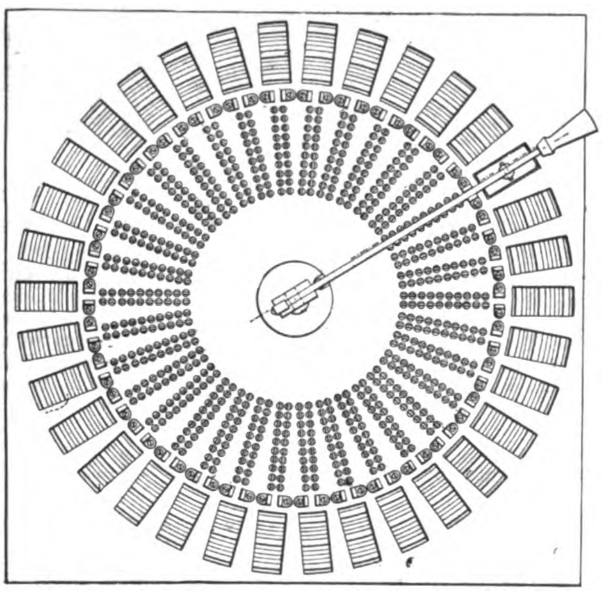

FIG. 4.—DIAL SWITCH FOR ILLUMINATED LETTER SIGNS.

expectancy engendered while the name or sentence is being spelled out adds to its advertising value. Of the single letter group one of the most interesting is now being manufactured and operated by Miner & Company, of New York City. It is the invention of Mr. Mortimer Norden. The lamps on the sign board are arranged as shown in the illustration, Fig.

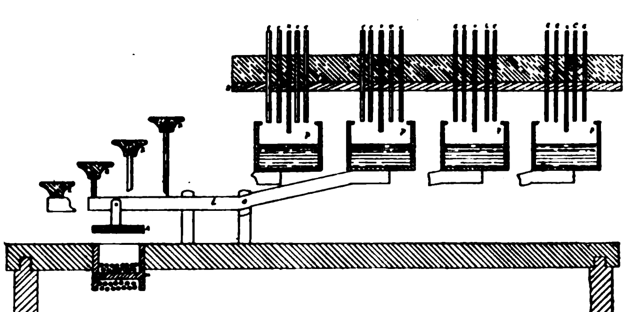

FIG. 5.—MERCURY SWITCH FOR ILLUMINATED LETTER SIGN.

1, on the board under the sign of Miner & Company. On inspection it will be found that any letter of the alphabet may be formed by lighting various combinations of these lamps.

The sign is operated from a machine very much like a typewriter in appearance, Fig. 2. It consists of a number of levers corresponding to the letters of the alphabet, which, when depressed at the front or button end make with the other end an electric connection between a number of clips, each pair of which corresponds to a lamp on the board. Every pair of clips forms the terminals of a circuit. The end of the lever coming between them bridges across the intervening gap. For instance, the wires attached to the lamps used in any one letter, are connected to a line of clips, A A A, in the rear of the operating machine, shown diagrammatically in Fig. 3. When the button, E E, marked with that letter, is depressed, the other end of the lever rises between the line of clips and every lamp necessary to the formation of the letters is thrown into circuit and lighted. The lever is held down by an electro-magnet, B B B, which is operated by the current. One lamp in series gives the proper current reduction for the magnet

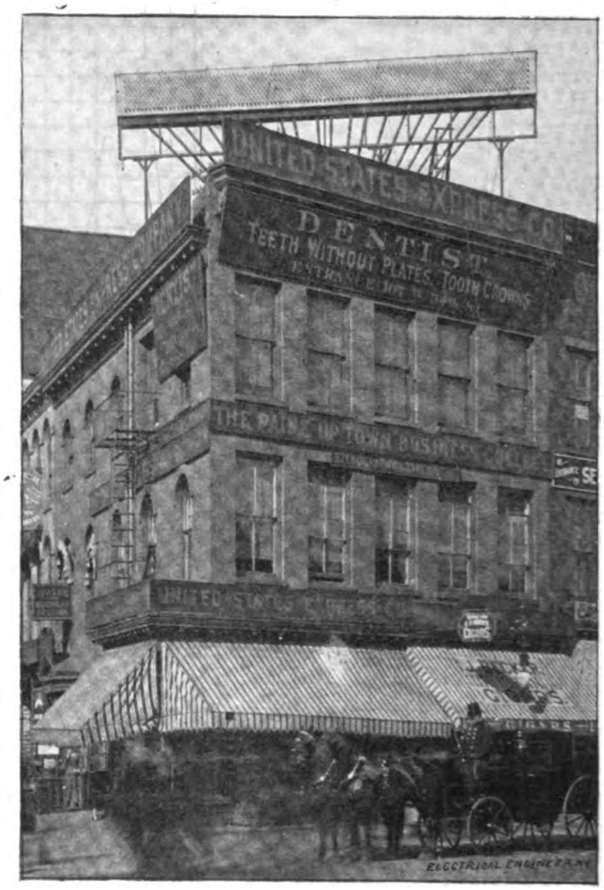

FIG. 6.—ILLUMINATED LETTER SIGN.

and the latter can be short circuited and the lever released by the simple pressure of a push button connection, D, arranged for the purpose, the lever being carried back to its original position by a spring. Naturally, some lamps on the board are used much more constantly than others in forming the letters, and much ingenuity and forethought was spent on the apparatus to so balance the wiring as to have it equal on both sides of the three wire circuit.

Messrs. Miner & Company believe in a board arranged with lamps as described, but they also operate several other entirely different machines for selecting the lamp letters. Another much more simple arrangement than the one just described is obtained when the clips attached to the lamp wires radiate from a center and are thrown into circuit by the simple shifting of a contact bar, as shown in Fig. 4. The latter would naturally carry the neutral leg in three wire systems. As many double clips or knife switches as there are lamps in a letter radiate from the center. As each pair of clips carries a wire from a lamp, it is obvious that when the knife bar, which can be turned to any point of the compass, passes between them, the letter formed by the lamps connected to any particular group will be lighted. As in the first machine, the bar once depressed is held in position by an electro magnet which thus keeps the desired lamp letter in circuit until short circuited by push button contact. The bar,

as in the first instance, is lifted from between the clips by a spring as soon as the magnetic action ceases.

The same firm is working on a mercury contact device which is intended to produce the same effect as accomplished by the above devices. Instead of making contact by a lever and clips, the end of every wire coming from the lamps is brought to and held in a position so that a mercury cup on being raised or depressed will make and break the circuit. The machine is in appearance like the one first described. The

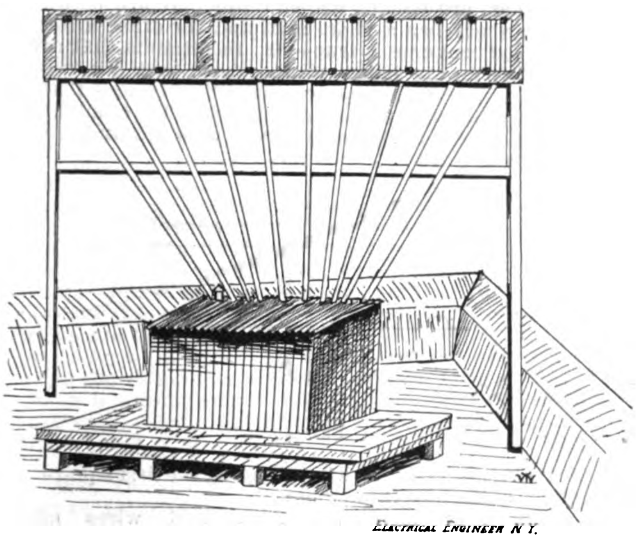

FIG. 7.—ILLUMINATED SIGN AND SWITCH CABIN ON ROOF.

ends of the wires coming from each combination letter on the board occupy a position pointing downward, Fig. 5. They are close together so that when the mercury cup, P, is raised on the end of a lever the points of the wires C C, are plunged into the mercury and a contact is at once made.

Still another device made by the firm consists of a series of metal tubes laid one inside of the other. The object of this is to do away with excessive wiring. There are as many tubes as there are lamps on the board. One wire runs from each tube to a corresponding lamp. A lever, as in the machine just described, operates between clips extending up from the tubes. Of course, only those tubes are included in a row of clips and consequently in circuit, as are needed for the lighting of each letter. This is the least complicated of all the devices thus far described.

Another single letter sign which has been operated by one

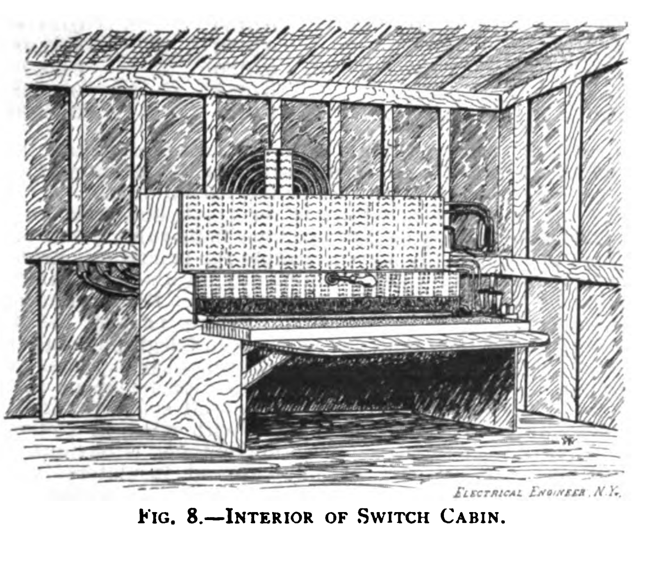

FIG. 8.—INTERIOR OF SWITCH CABIN.

of the New York daily papers is built on the typewriter principle. The contact is made differently, however. Instead of the opposite end of a lever rising between clips, the part directly under the depressing button makes contact with a piece of metal beneath it. But there is no magnet to hold it in position, and the great objection to it is its propensity for arcing. Its most unique feature is the arrangement of lamps on the board. The latter is, so to speak, a frame arranged in the form of a square, carrying its diameters and diagonals. The whole affair is covered with lamps arranged in the same manner as the frame. There is also an extra lamp at each corner to complete the design of some letters. Nearly every letter of the alphabet may be obtained on this sign. The contrivance is designed by Mr. Mason, of New York.

A typical example of the second class of interchangeable electric signs may now be seen in nightly operation on the roof of a building at Thirty-fourth street and Broadway, New York City. The sign, Fig. 6, as far as the public is concerned, is a solid oblong bank of lamps, out of which any letter, sentence or legend may shine at will. As a matter of fact there are 1,084 10-candle-power frosted lamps in the bank. The selecting apparatus is located in a frame structure built on the roof of the building under the sign, as shown in Fig. 7. The lamps on the sign are placed as close together as is possible without actually touching. The sign itself is located high above the roof and the cables are conducted up through heavy iron pipes.

The most interesting part, however, is the selecting apparatus. Its arrangement is unique. The operating table, Fig. 8, is made of slate. It lies flat and is bored full of quarter-inch holes. There are 1,084 of these; one for every lamp on the sign. The holes are half full of mercury, and each one connects by wire with a lamp. A three-wire circuit is used, the lamps naturally being evenly balanced between the positive and negative. The neutral leg is attached to a metal mercury trough which occupies a position along the edge of the board. The only thing necessary to complete the circuit is to connect the mercury in the holes with that in the trough. The letters are then formed in this simple manner.

The desired letters are marked out on a brass plate and brad nails are soldered on to it just far enough apart so that when the brass plate is inverted, the nails forming the letter will stick down into the proper holes. The brass plate is also made to connect with the mercury trough by means of an extra lug or hook soldered on to one end of the brass plate. Any letter or series of letters may thus be formed and the constantly changed sign is an object of such interest that it is nightly gazed at by crowds of people. Every lamp is properly protected by fuses, as are also the sections of the bank so that no unusual stress is possible. The sign and apparatus is owned by the Electric Sign Advertising Company, of New York. The work on it was done by the New York Electric Equipment Company. Power is supplied by the United Electric Light & Power Company.

TELEPHONY AND TELEGRAPHY.

THE TELEPHONE TRUNK LINE SYSTEM IN GREAT BRITAIN.—I.[1]

BY J. GAVEY.

THE author gave a brief history of long distance telephony, dwelling principally on the difficulties which were encountered. These consisted of : 1. Induced currents due to electromagnetic induction. 2. Induced currents due to electrostatic induction. The action of these disturbances was illustrated graphically.

The conditions which are necessary to obviate interference, due to the above causes, between two neighboring circuits, one of them at least being a metallic loop, are the following.

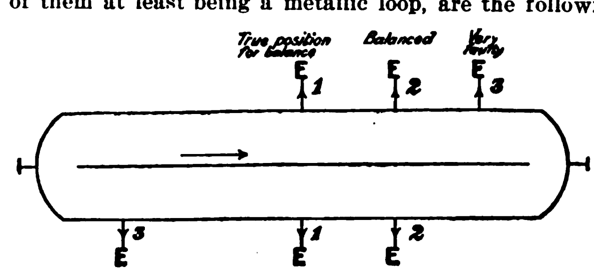

FIG. 1.

For practical purposes each circuit which has great length compared to its depth is considered to consist of two sides alone, the ends being negligible.

1. Each of the wires of one loop should maintain throughout the same or an average equal distance from each of the wires of all neighboring loops.

2. The two conductors of each loop should be of the same material.

3. They should have the same conductivity.

4. Each half of the circuit, including apparatus in direct circuit, should possess the same co-efficient of self-induction.

[1] Abstract of a paper read before the Institution of Electrical Engineers, London.

5. They should have similar electrostatic capacities.
6. They should have the same degree of insulation, whether high or low.
7. The resultant faults due to loss of insulation should be in the center of each wire of the loop; but if not there each should occupy similar positions at equal distances electrically from the extremities.

Conditions 1 to 5 are readily met, and, once attained, they are stable. No. 6 is more difficult to ensure, for the insulation of either arm of a loop may at any time be lowered by innumerable accidental causes, so that the most careful attention to maintenance is necessary to remove this source of trouble. No. 7 is at times a source of considerable difficulty, especially in the case of telephone trunks erected on poles carrying high-speed Wheatstone wires, when the latter are worked with shunted condensers. Thus, in Fig. 1, with the resultant earths at points 1, points 2, or at other symmetrical positions, the circuit is silent; but with positions 3 disturbance becomes evident, for the currents entering at these points traverse the telephones in establishing the electrostatic redistribution. Normally, the currents due to electromagnetic induction would be more considerable than those arising from electrostatic induction in a single-wire circuit with an earth return.

The methods of construction of telephone trunk lines differ but slightly from those adopted in the erection of ordinary telegraph lines, the principal difference arising from the necessity for providing the balanced circuits referred to above.

Taking, first, the simple case of two contiguous metallic circuits, if they be arranged so that the two arms of each loop are at diagonally opposite angles of a square (Fig. 2.), then the condition No. 1 is observed, and the circuits are balanced for distance whether the wires are run straight or whether they revolve; and in a similar manner a loop on a horizontal arm (Fig. 3) is balanced against a single wire on a saddle with an earth return, so long as the single wire is at the apex of an isosceles triangle of which the loop forms the base. With this exception, to obtain a balance between one loop and a second circuit external to it, whether metallic or with earth return, the wires of each loop must revolve uniformly the one round the other. In underground work this revolution is a uniform spiral, but with open work the wires simply change their positions regularly on each successive pole. In England the method adopted is almost uniform, and it consists in continuous changes of position, every wire being moved transversely at an angle of 90 degrees at each pole, so that a complete revolution is effected in every four spans. Other methods of crossing have been adopted on the Continent, but the above is perhaps the most simple way of achieving the end in view. In some cases the wires are run parallel, and crosses introduced at intervals to obtain an approximate balance.

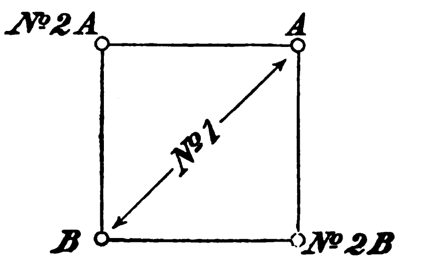

FIG. 2.

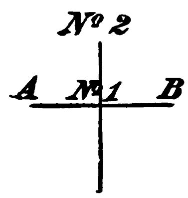

FIG. 3.

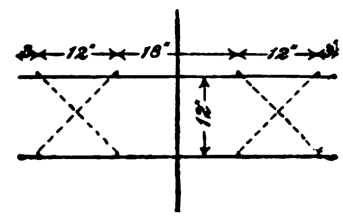

FIG. 4.

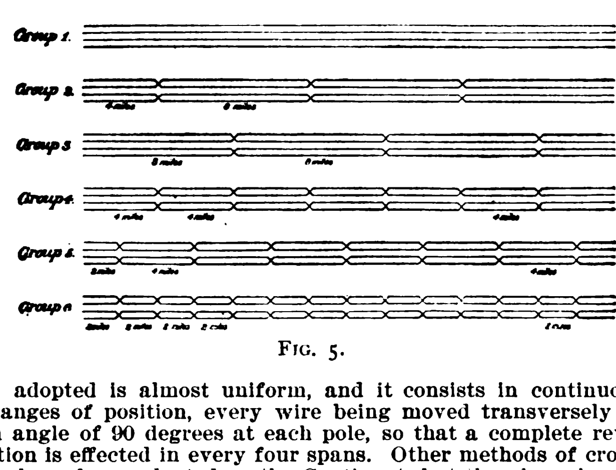

FIG. 5.

The present practice is to erect four wires on arms 48 inches long, divided as shown in Fig. 4, the arms being fixed on the poles 12 inches apart from center to center. Thus two arms provide space for four metallic circuits, the four wires on each side of the pole forming a section of a 12-inch square, the diagonal wires in these squares being taken up by each circuit.

Of course, as previously pointed out, the two diagonal circuits in one square are perfectly balanced against one another, and therefore free from mutual disturbance; but in dealing with a large number of telephone loops, if the relative average distance between each of the two wires of any one circuit, say, in the right-hand square and those of the two wires forming each circuit in the left-hand square be measured, it will be found, when all wires have the same twist, either right or left-handed, that the average distances between wires of the circuits, the diagonals of which are at right angles to one another, are equal., whilst those that are parallel are not. If one square has a right-hand and the other a left-hand twist, then the converse is true—viz., the circuits that are parallel at each pole are balanced and those that are traversed are not. It is found in practice that disturbances that arise between neighboring twisted circuits can be eliminated by crossing systematically. Thus, dealing with a number of circuits on one route, the four wires forming the first square may be revolved uniformly throughout.

The next four have the A and B wires of each circuit crossed eight miles from the starting point, and at intervals of eight miles onwards. The third group have the first cross four miles from the former point, then the remainder of the crosses succeed at intervals of eight miles. The wires of group 4 are crossed throughout at intervals of four miles. Those of group 5 have the first cross two miles from the terminals then the remainder of the crosses at four mile intervals. Group 6 is crossed at intervals of two miles. It will be observed, on examination of Fig. 5, which illustrates the arrangement, that each circuit is balanced against all the neighboring ones; and by this simple method it has been found possible to establish a series of wires absolutely free from overhearing.

The resistance and the inductive capacity of the various overground wires used in practice are as follows:

Lbs. per m.	Resistance. Stand. ohms.	Capacity to E.	Capacity, wire to wire.
100	8.782	0.0144	0.00864
150	5,·54	0.0147	0.00882
200	4,391	0.0150	0.00900
300	2.929	0.0153	0.00918
400	2.195	0.0156	0.00936
600	1.464	0.0158	0.00948
800	1.098	0.0160	0.00960

It will be observed that with the standard distances at which the wires of a loop are erected in this country the capacity, wire to wire, is 0.6 that of the wire to earth.

The use of underground wires for trunk lines was utterly impracticable so long as gutta-percha, india-rubber, and other kindred materials only were available for insulating purposes. The introduction of what is practically an air-space cable by the use of paper insulation appears to offer the solution of a difficulty looming in the immediate future, namely, the finding of space for the numerous wires, both telegraphic and telephonic, which will be required between busy centers. Unfortunately, the need for two wires for each telephone circuit results in the rapid filling up of all aerial supports; and the undesirability of overcrowding poles with wires in a climate like ours, subject to snowstorm interruptions, is obvious.

Hitherto, the capacity of underground insulators, which roughly equalled 0.3 of a microfarad per mile, seriously limited the use of subterranean conductors. The capacity to earth of paper cables has already been reduced to a figure varying from 0.06 to 0.08 microfarad per mile with small conductors weighing 20 pounds to 40 pounds per mile; and although these are not well adapted for long trunk circuits, their use for relatively short circuits will soon become general. For heavier conductors weighing 100 pounds or 150 pounds per mile, the capacity to earth is about 0.1 microfarad per mile. At the end of the year 1895 the mileage of telephone trunk wires in Great Britain and Ireland, actually complete or in course of completion, had reached the following figures:

	Miles.
Postoffice system	20,522
National Telephone Company's system	28,999
Giving a grand total of	49,521

Further and rapid growth may be confidently expected, so that the present mileage will soon be largely exceeded. Every great town in the country is, or will be, connected with the telephone trunk wires of the State; and it is probably not unsafe to predict that within the course of a few years practically the whole of the commercial business of the country will be transacted by telephone. In the neighboring manufacturing and commercial districts this condition of things has already been nearly attained.

The method of working the telephone trunk system of the country, with due regard to all the interests at stake, has been a matter of careful consideration on the part of the Postoffice Department in conjunction with the responsible officers of the Telephone Company.

The general system adopted is as follows: All the trunk circuits are terminated at the respective postoffices. Connection between the trunk and the local subscribers' switches is established by means of "junction circuits." For each trunk circuit one junction is provided to the local postoffice switch, and one to the company's principal exchange switch. These junctions are used solely for switching.

For conveying instructions, call or service circuits are established in the ratio of two circuits to each local switch for every 20 or less number of trunks. Half these circuits, known as "up" call circuits, connect the local switches with the recording tables, and they terminate in headgear telephones which are worn continuously by the ticket operators. The other half, known as "down" call circuits, serve to connect successive groups of 20 trunk jacks direct with the switches of the local subscribers, and they likewise terminate in headgear telephones.

At the smaller offices, where a few trunk circuits only exist and the traffic is but slight, the call wires are fitted with indicators, and at the larger offices the call wires are terminated on indicators during the slack periods, as it would obviously be absurd to retain an operator listening continuously for a few intermittent calls.

The method of working is, briefly, as follows: A demand for a trunk call is conveyed to the local switch operator; the latter at once, without initiatory ring or signal, transmits the request to the recording operator, who enters the particulars on a ticket, which is then timed in telegraphic code and sent to the trunk section affected. It may thus be said that a local subscriber's want is immediately made known to the trunk operator at the neighboring postoffice; although the actual time of putting through and the commencement of conversation depend, of course, on the number of prior calls, and the time lost in obtaining the distant subscriber's attention.

When the call matures—i. e., when the trunk circuit is free, or previous calls have been disposed of—the trunk operators at each extremity come in on the "down" call circuits, and request the junction operators to join specified junctions through to the subscribers who are wanted. This done, the trunk operators then ring up the subscribers, and on receiving replies they connect them direct to the trunk circuit.

HAWAII REFUSES AN AMERICAN CABLE FRANCHISE.

A special dispatch from Honolulu, of Nov. 17, says: A new contract has been proposed by the Pacific Cable Company, which organization includes such men as D. O. Mills, former Mayor Hewitt, of New York, and Mr. Hill, of the Great Northern Railway.

This company asks for a contract by which they are to have two years in which to obtain concessions from the Japanese Government and the Australian colonies relative to the laying of cables from Hawaii to Japan and from Hawaii to Australia. The company offers to purchase $375,000 of the new 4 per cent. Government bonds, presumably at par, and to forfeit $125,000 in case an inter-island cable is not laid within a year. If the desired concessions from either or both Japan and Australia are obtained within two years the company will forfeit $125,000 in each case if it fails to construct the cable within three years thereafter. On these lines they ask twenty years' exclusive franchise.

Acting Minister of Foreign Affairs W. O. Smith yesterday notified John W. Foster, attorney for Col. Z. S. Spalding, that after due and careful consideration on his request for an extension of concessions already granted to Colonel Spalding the Government has decided that it is not advisable at this time to extend any of the franchises or privileges he may now have regarding the laying of a cable from the United States to Hawaii so as to include an exclusive franchise for a cable line between Hawaii and Australia or Japan, or both. While the Government regretted that it was unable to comply with the request, the executive wished to express hopes for Colonel Spalding's success in building the line originally proposed between the United States and Hawaii.

THE TELEPHONE IN THE EDUCATION OF DEAF MUTES.

According to the experiments of Dr. Bertram Thornton, the telephone promises to be of material use in the education of those deaf mutes who possess a fragment of hearing power, and it has this advantage over the single speaking tube, that is sometimes used. In the first place, with it a teacher can instruct a group of children at the same time; secondly, it is not necessary for the teacher to apply his mouth close to the transmitter, the pupils have a full view of his features, expression and lip movements, which is not the case when he has to direct his attention and his voice into the mouth of the speaking tube or trumpet. It is well known that in most cases of deafness the actual hearing part of the apparatus, so to speak, is capable of performing its function, but the mechanism for collecting the sound waves and transmitting them to the cochlea and its appendages is defective. This is also the case in a large proportion of instances of deaf-mutism. In using the ordinary speaking tube, the voice of the speaker is increased in intensity to an almost painful degree, and the lips have to be placed close to the mouthpiece. By using the telephone an intensification of the voice at least equal to the most improved form of ear trumpet is obtained at a distance varying from 6 inches to 1 foot from the mouth of the transmitter. Dr. Thornton has found this fact an immense help in the teaching of deaf mutes. He mentions two cases in which the utility of the telephone was materially manifested. The first was that of a young woman with nerve deafness so extreme that it was necessary to speak at the top of one's voice within two or three inches of her ear to enable her to hear. With the telephone he was enabled to converse with her in a subdued voice, with his mouth twenty-six inches away from the transmitter. In this case she received some assistance from reading his lips, though she was only a beginner in the accomplishment. In another case, a man with a similar degree of deafness was able to hear his wife and another person conversing with him in tones raised hardly above a whisper, they being inside the room and he outside, with the door shut. The value of the telephone in deafness, it is claimed, is not yet half appreciated, and many progressive aurists are now devoting a good deal of time to the study of the subject.—Ex.

GOVERNMENT TELEGRAPH WIRES.

Gen. A. W. Greely, chief signal officer of the War Department, in his annual report says that interruption to telegraph communication has been so infrequent during the year as to be practically nil. The most frequent cause of interruption has been maliciousness, through a tendency of lawless individuals to pull down poles, cut wires or shoot off insulators. The speedy resumption of communication after such occurrences has been due to a great extent to the adoption of the bicycle as a means of transportation for repair men in place of the more expensive horse and wagon. The bicycle affords the more rapid as well as more economical method of travel. Frequently breaks in a line have been repaired by the use of the bicycle in less time than would have been consumed in obtaining a horse and vehicle. At some stations in a single year the original value of the bicycle has been saved to the Government.

LAYING SUBMARINE TELEPHONE CABLES AT TOLEDO, O.

The Central Union Telephone Cable has recently laid 900 feet of fifty pair submarine cable across the Maumee River, at Cherry street, Toledo, O., in two cables, each 450 feet long, under the direction of Mr. E. M. Jackson, superintendent of construction. This cable is made up of seven strands of No. 28 wire, American gauge, twisted together. Each of these stranded conductors is insulated .145 inch with okonite. Each pair of conductors is twisted in spirals 3 inches long laid up with jute and armored with No. 6 iron wire galvanized. The cable, which was made by the Okonite Company., Limited, is buried in the river bed, the laying being done by an expert diver. It is secured at each bank in such a manner that if at any time it is hooked and dragged by passing craft it will tear away from the terminal box, but will be recovered by means of the twisted wire stay rope.

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—X.

BY LIEUT. B. A. FISKE, U. S. N.

THE ELECTRIC TELESCOPE SIGHT.

At 2,000 yards, a ship of twenty feet freeboard subtends a vertical angle of less than one-fifth of a degree. The distance at which a gun captain stands behind his sights may be said to be 120 inches from the front sight and 60 inches from the rear sight; so that this angle of 1-5 degree is represented on the front sight by about 2-5 of an inch, and on the rear sight by about 1-5 of an inch. Now, in order to shoot correctly, the gun captain must fire so that the projectile will leave the gun just when the exact points of the two sights are in line with the target. It is not very easy to do this, as the records of gun practice at sea most sorrowfully prove.

A little reflection will show why correct firing is so difficult. In the first place, the construction of the ordinary bar sights is such that, unless the sights are on a level with the target in a vertical plane, it is extremely difficult to tell if they are pointed in the proper direction in a horizontal plane; and not only this, but when the ship is rolling away from the target, the rear sight and the gun itself masks the target completely; in the second place, the line of sight sweeps over the entire vertical target in 1-5 of a second (supposing that the ship is rolling 1 deg. per second, which is very slowly), so that the gun captain has only one-fifth of a second of time in which to make up his mind whether the sights are on the target, and to fire if they are on the target. Now the three objects which he is trying to get into line are the target, the front sight and the rear sight, of which one is 2,000 yards distant, another about 10 feet, and the other about 5 feet; so that he is called upon instantly to focus his eye on three points at distances of 2,000 yards, 10 feet and 5 feet, and the human eye is so constructed as to make this impossible. But the formidable difficulty is that, during the one-fifth of a second in which the gun captain must do the things above enumerated, he must, in addition, have the pupil of his eye behind the rear sight in an exact line with the line prolonged from the front sight to the rear sight. If the pupil of his eye is not exactly on this line he cannot recognize the instant to fire, except approximately, and if his eye be as much as 2-5 of an inch above or below the line, and he fires when his front or his rear sight rests on the target, his gun will really be pointing 20 feet above or below the point of the target on which the sight rests. It is not an answer to point out the wonderfully fine shooting done by some men, because the records of target practice show that such shooting is, to say the least, exceptional. Now, a telescope of large field and small magnification has been found to practically eliminate all the errors of sighting, and to make it possible and easy for an ordinary man, with hardly any practice at all, to shoot fairly well always, and badly never, as was proved before an official board in the U. S. S. San Francisco, by the writer using in many cases absolutely untrained men, including firemen and coal heavers.

(Twenty-nine shots were fired, each shot counted either 5 or 4 (5 being the maximum). The deviation of the projectile to the right or left, as observed from the ship, was so small in each case that it could not be measured with any means at hand; it was therefore estimated, using the known dimensions of the target as reference. Sixteen out of the twenty men firing had never used the sight before. One man who made an average of 90 out of a possible 100 had never, so he stated, fired any kind of a gun, musket or pistol.)

The large clear field of view with the two cross-wires, one vertical and the other horizontal, lets a gun captain see (even when the horizontal wire is far below or above the target) just how much the gun must be moved to the right or left; everything is exactly in focus, so that there is no strain on the eye whatever, and (which is the most important), the gun captain cannot sight wrong even if he tries. He cannot take a fine sight, or a coarse sight, or a bad sight. The cross-hairs are either plainly on the target, or plainly not on the target; and just so long as he looks through the telescope at all, he can see the cross-hairs in only one place, and that is in the fixed axis of collimation of the telescope. Since a telescope can be made to endure about as much rough usage as a football, it is surprising that any sights except telescope sights are used in modern ships. Of course they cannot be used on the guns themselves, because the guns recoil, but they can be placed on some non-recoiling part of the gun-support laterally moveable with the gun. The latest form of telescope sight has a field of view of 19 deg. in each direction, with a magnification of about two diameters, and is so strong as to be less liable to injury in service than is the ordinary long bar sight; so it can be kept in place all the time, ready for instant use. In order "to make assurance doubly sure," a strong sheet-iron cover thoroughly japanned is arranged to cover the sight when it is not in use.

A ship which can adjust her gun sights quickly, when the range is changing quickly, will have a great tactical advantage over a ship which cannot. It has been found, in practice, when the range is changing rapidly, that the range finder and range indicator can measure and signal ranges so rapidly that it is impossible to set the sights and get ready to fire before a new range necessitates a new adjustment of the sight.

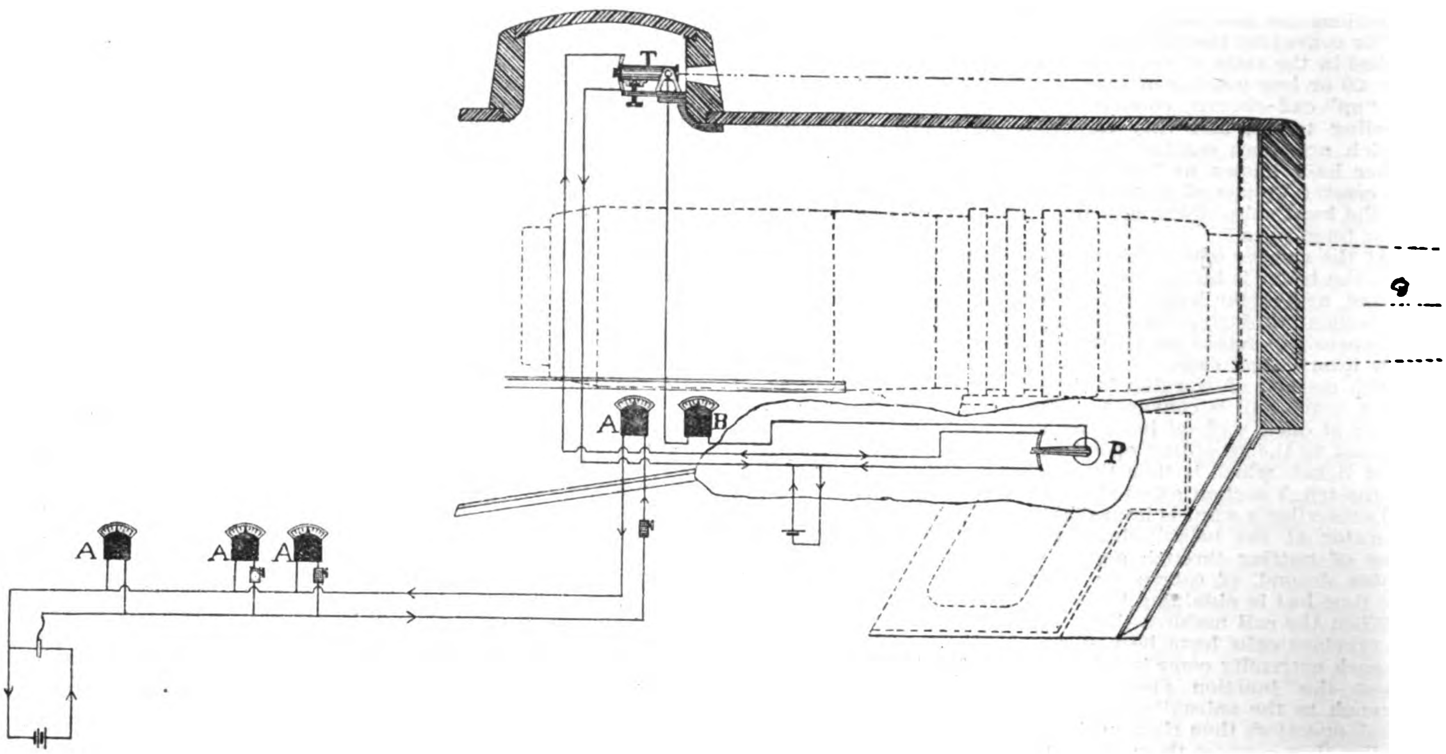

FIG. 34.

To secure the tactical advantage to be obtained by meeting this difficulty, the electric telescope sight has been devised to so work in co-operation with the range indicator, that the setting of the sight occupies but an instant, and does not interfere with the firing of the gun, or distract the attention of the gun captain.

As shown in Fig. 34, one of the receivers of the range indicator circuit is placed alongside of a similar indicator, which shows the distance corresponding to the angle between the bore of the gun and the line of sight of the telescope, placed in the sighting hood above the gun. Evidently the telescope and the guns are converged at the correct angle when the indicators indicate the same distance.

The operation is as follows: The gun-firer places his telescope at whatever position in the vertical plane he finds convenient. He does not need to know the range, except approximately.

The elevator man watches both the range indicator and the gun elevation indicator, and merely works the elevating mechanism so as to make the latter read the same as the former.

When the gun-firer sees his cross-hairs rest on the target, he presses the electric firing button.

To prevent his firing when the indicators indicate differently, the firing circuit is broken at two places—one place being his firing key and the other place being a similar key near the elevator man. The gun cannot be fired unless both the elevator man and the gun-firer press their keys; and neither presses his key unless he is ready. The elevator man keeps pressing his key so long as the two indicators indicate the same thing; but, if the range suddenly changes, he releases his pressure on the key until by moving the elevator wheel he has made the gun elevation indicator indicate the correct distance; he does the same thing, if the gun-firer changes the position of his telescope and the indication of the gun elevation indicator. It will be noticed that this operation on the part of the elevator man is a very simple one, since he merely has to move his wheel a fraction of a revolution in one way or the other, to keep the needle of his indicator at the same mark as the needle of the range indicator beside it.

On the base of the telescope sight are arrangements for correcting for speed and drift. The electric sight has not yet been tested in service, but it is merely a combination of the

Horizontal field in gun port = 9.5°. Vertical field = 3°. Eye of gun captain being 60 inches behind rear sight. Ship is 2,000 yards distant.

mechanical telescope sight with a simplified form of the helm indicator and steering telegraph.

In the case of guns that recoil along the line of fire, especially with the smaller calibers, the telescope sight is attached directly to the support of the gun, which moves laterally and vertically with the gun, but does not recoil.

Fig. 36 shows the field of view of the telescope sight which the writer mounted on the support of a rapid-fire gun on board the Yorktown in 1892, and afterwards in the U. S. S. San

Francisco in 1893 and 1894, the gun being frequently fired in both ships to test the sight. Fig. 35 shows, in comparison and on the same scale, the field of view obtained looking through the port in the gun shield, when using the ordinary sights on a 6-inch gun, in the Yorktown, on the shield of which the sight was tested.

LITERATURE.

AMERICAN TELEGRAPHY; Systems, Apparatus, Operation. Second Edition.—By W. Maver, Jr., New York. Wm. Maver & Co. Cloth. 450 illus. 564 pages. Price, $3.50

We are glad to see this valuable and useful book reach its second edition, and to know that the sales continue steadily large. It is not merely a reprint in this case, but the matter has been revised and added to, there being about 7,000 words of additional matter and 11 new cuts. Among the new things and topics introduced are the storage battery in telegraphy; new repeaters; the Morris duplex with battery at one end; Burry self-winding stock transmitter; motor transformers for furnishing current; new W. U. standard quad; new polarized and neutral relay, etc. As usual, everything is done carefully and thoroughly, and the book remains one on which the author can safely stake his reputation as a consummate master of the theory and art of telegraphy. It is a book without which no electrical library is complete, a book that every ambitious and conscientious telegrapher should know intimately from one cover to the other. Various improvements have been made in the general get-up of the book which is a handsome, well printed volume.

OUR NEW PRESIDENT, MARCH.—By Juliet S. Norton, Union Mutual Music Co., New York.

Miss Norton's new march has the ring of victory. The word "triumphal' has been purposely omitted, it is evident, as the music tells its own story. The leading theme is pleasing and characteristic, and is agreeably relieved by a variant in the bass with a treble accompaniment, working up to an excellent close. The march should be popular.

MARRIED.

MR. F. S. PALMER, general manager of the Electric Heat Alarm Company, of Boston, was married on Nov. 30, to Miss Nellie Lauretta Schultz, of North Cambridge, Mass., and will be at home, 56 Frost street, North Cambridge, on Wednesdays after December 9. Mr. Palmer is well known in the East and has received congratulations from hosts of friends, who all wish him well.

CONTENTS.

THE CAPITALIZED VALUE OF INTELLECT IN INDUSTRIES.

IT is said, and probably with truth, that there never was a time when intellect enjoyed a larger share of the increment of wealth, in the shape of profits and salaries than at the present time. Ability to manage and direct is paid for at a high rate, and the services of men of executive talent are actively in demand. The tendency of the times toward the massing of capital and enterprises is the reason for this, and the economy resulting from skillful direction explains also the increase in the reward of labor, either directly or by the shortening of the working hours.

Yet when the creative and organizing faculty is reduced to a basis of capital, there is often an outcry, and to-day much of the agitation against the "watering of stock" is aimed at the share which goes to the far-sighted planner of the enterprise, who not only saw the new opportunities, but seized them and made them yield profit not only to individuals, but to the world at large. This is the trouble with so much of the current socialism; it acts as a discouragement to genius and would deprive inventor, writer, organizer and artist of his part in the returns from new work. We are glad to find this aspect of a social problem dealt with clearly and ably by Mr. T. C. Frenyear, a gentleman well known in electrical engineering circles, who has contributed to the last number of the "Annals of the American Academy of Political and Social Science," an excellent article on "The Ethics of Stock Watering." His main, and incontestable, proposition is that the value of contributions to an undertaking not in tangible property or cash, should be generally recognized by capitalists, by the public and in legislation.

Incidentally, there is suggested to us by Mr. Frenyear's thoughtful article one reason why newspapers, lay and technical, are almost invariably, to a greater or less degree, on what may be called the anti-monopoly side of great questions. The technical press, for example, is constantly required by duty to build up new industries in its field, but it must always be averse, by the very nature of things, to a state of affairs which would assign to a few persons all the profits of that industry when built up and would thus tend to bar out the press from the natural rewards of its own efforts.

Turning to another aspect of a large question, we find the flaw in the argument for much of the proposed municipalization of various enterprises. Every time the matter comes up, it is said that the government or the municipality can create such and such a plant for so much, ergo, the existing plant must go out of business or be surrendered at a bald, sheer cash valuation. But what of the antecedent brainwork, the invention necessary to call new apparatus into existence, the local enterprise and energy that furnishes a given spot with the new facilities, the energy and organization that reaches out to meet the new wants and new demands of larger and larger areas of supply? These are surely entitled to some recognition and reward. But if one accepts the views of a nationalist like "Prof." Frank Parsons, of Boston, as enunciated again by him last week, when the municipality does not crowd out private enterprise, it is only to tax it down to the last degree of endurance on its actual cash value. The benefits derived by Boston to-day from its rapid transit system, inadequate like the systems of every other large city, are simply tremendous when compared with the relatively small profits reaped by the West End system by its remarkable enterprise and its huge expenditure. The clamor for a two or three-cent fare is based on the same short-sighted idea that all an enlightened city should permit is a pittance for courageous capital and nothing for exceptional brain power.

We cannot but agree with Mr. Frenyear that the "unearned increment" is often that which is most truly earned. It does not belong to the public necessarily, nor does it by any means always reach its rightful owners; but when the civilized world

gets through with rewards to its pioneering spirits, there will be no more increments at all for anybody.

THE PATERSON CENTRAL STATION.

AMERICAN central station engineering has, until recently, scarcely been a credit to the profession, but many of its shortcomings are unquestionably the relics of a pioneer period and to that extent ought not to be too harshly criticised. The large companies in the cities of the first magnitude, such as New York, Boston, Chicago, and a few others, were the first to inaugurate a more scientific era of central station construction, and their example is now being rapidly followed by companies in other places of lesser size. Prominent among these is the Edison Illuminating Company, of Paterson, N. J., whose station we describe in detail elsewhere in this issue. It is indeed a matter for congratulation to find an electric plant of this nature designed with the fixed purpose of equipping it only with the best and most advanced apparatus which the art affords, in regard both to the electrical and to the steam equipment. What lends additional interest to the Paterson station is the fact that it is a composite station, in so far as it supplies current for incandescent and arc series lighting as well as electric railway current. The economies possible in a station of this type must be apparent. We believe that more of these plants will be installed in the near future, or rather that the older plants which have outlived their usefulness will be "scrapped" to make way for modern high duty apparatus.

Much credit is due to Mr. W. M. Brock, of the Paterson Co., for the manner in which he has added to the models in central station plants of which there are but too few for the good of the industry. Mr. Brock has had the courage of his conviction that Paterson could support a first-class station just as well as New York or Chicago could.

TRANSMITTING POWER TO CITIES.

ONE of the most striking of modern developments in electricity is the manner in which adjacent water powers are being annexed by large cities. The recent transmission of power from Niagara to Buffalo is but one episode in a great development which hardly yet attracts the attention that it deserves. Instances already become numerous, but if the work goes on at the present rate, power transmission plants will soon be among the commonplaces of electrical enterprise. What is more particularly noticeable is that distances of 20 or 30 miles no longer count, at least in this country. Perhaps the best instance in Europe is still the 19-mile transmission from the Falls of Tivoli to Rome, but here examples of that magnitude multiply. The American cities that have absorbed distant water powers just as they absorb suburbs are by no means few. Buffalo has reached out electrically 22 miles to Niagara; Fresno, 35 miles to the San Joaquin River; Portland, 14 miles to the Willamette; San Bernardino, 29 miles to the San Antonio Mountains; Hartford, a dozen miles to the Farmington River; Salt Lake City, a good ten miles to the Big Cottonwood Canyon and the Wahsatch Lakes; Sacramento, more than 22 miles to Folsom. Supplementary to these come the installations now operating, or in process of construction, at cities such as Austin, Tex.; Riverside, Cal.; Springfield, Mass., and Minneapolis, Minn.

So far all this work has depended on the utilization of water power, but it is not unlikely that in the near future we may see the energy of coal transformed at the pit's mouth in the same way, and sent a long distance over aerial wires instead of in cruder form over iron tracks. There does not seem to be any specially good reason why Pittsburg should burn coal and remain dirty, when the coal might just as well be burned somewhere else, oustide the city limits; for if it were not cheaper to resort to electricity, it might pay to get out the gas and pipe that. People do not use any milk or cheese or butter the less nowadays because the cows are kept in the country.

ADVANCE OF ELECTRIC TRACTION.

AS we go to press this week two important items of news reach us as to further gains in behalf of electric traction. One is to the effect that the New York, New Haven and Hartford is to equip at once some of its short lines in the vicinity of Hartford with the third rail system, to be running in the spring; and that a power-house is to be built at Berlin for the work. Another item of equal importance is that the Metropolitan Company of New York is to equip its Fourth and Madison, Sixth avenue and Eighth avenue lines all with the underground trolley system, on the model of the Lenox avenue line. As was to be expected, the compressed air system has been tried and found wanting again for the purposes of city street traction; and it would appear that while the Metropolitan is satisfied with the cable on Broadway it does not want any more of it.

THE CONSISTENCY OF A CAPTIOUS CRITIC.

WE append two items, both taken from the same issue of the London "Electrical Review," a very nice little paper when not suffering from the mental dyspepsia which in the present instance, prevented its right foot from knowing what its left hand was doing. The paper for which the "Engineer" is jumped on so savagely was that read by Mr. McCulloch before the Am. Street Ry. Assn., and printed by at least a dozen technical journals. As will be seen, the London "Review" itself praises the paper in one place although pouring green bile over it in another. We trust our contemporary will soon be convalescent, clear-headed, and able to spell correctly:

"Our contemporary, The Electrical Engineer, of New York, does not pose as a comic paper, but none the less it succeeds in producing matter eminently entertaining to the average Britisher. In the issue of November 4 two columns were devoted to the discussion of steam power plant under the above exceedingly suggestive title (Steam Consuming Apparatus). A few months ago American lighting and power stations were considered as national asylums for the makers and sellers of leather belting, and not by any means the least instructive part of the said article is that which trots out the direct coupled plant as a modern development of American practice, whereas, notwithstanding that Edison long ago produced direct coupled plants, it was on this side of the water that the advantages of direct coupling were first fully explained and insisted on. The result is that probably neither here nor on the Continent could a single editor be found who would devote even so much as a single paragraph to the discussion of such an antidiluvian (sic) subject." Page 655.

"Few things could possibly better illustrate the difference between 'street railway' (i. e., tramway) enterprises in the United States and in this country, than the reports of meetings held by the respective tramway associations. Here, the Tramways Institute hears papers upon, and desultory discussions concerning, car starters of the coiled spring variety, new ideas in horse-shoes, or the best kind of winter food—varied by occasional references to gas motors or complicated conduit systems: over in the States they discuss matters dealing entirely with mechanical systems—and a typical bill of fare is that just gone through by the American Street Railway Association at their annual meeting, held this year at St. Louis. The subjects dealt with include such questions as 'Tracks and Track Joints: Construction, Maintenance and Bonding;' 'Trucks;' 'How to Increase Revenue by Transfers, etc.;' 'Modern Overhead Construction;' 'The Modern Power House;' 'Selection and Management of Employés,' etc., all of these being topics of a live and interesting nature." Page 666.

The "antidiluvian" matter referred to on page 655 was part of the "Modern Power House" paper, and is here properly mentioned as "live and interesting," on page 666. It is difficult, of course, to please both Dr. Jekyll and Mr. Hyde.

Electric Transportation.

MOTOR CARS ON THE BROOKLYN BRIDGE.

THE trains on the Brooklyn Bridge are now entirely operated by electricity, and the noisy, puffing, little steam locomotives in use since the first train was hauled across the Bridge have been at last discarded. The change was effected on November 30, when twelve motor cars were put into service operating the trains in conjunction with the cables more quickly, quietly and more satisfactorily than the steam motors. Fourteen motor cars are now in service, and the remaining six car equipments are being installed as rapidly as possible, to be put into service as soon as completed.

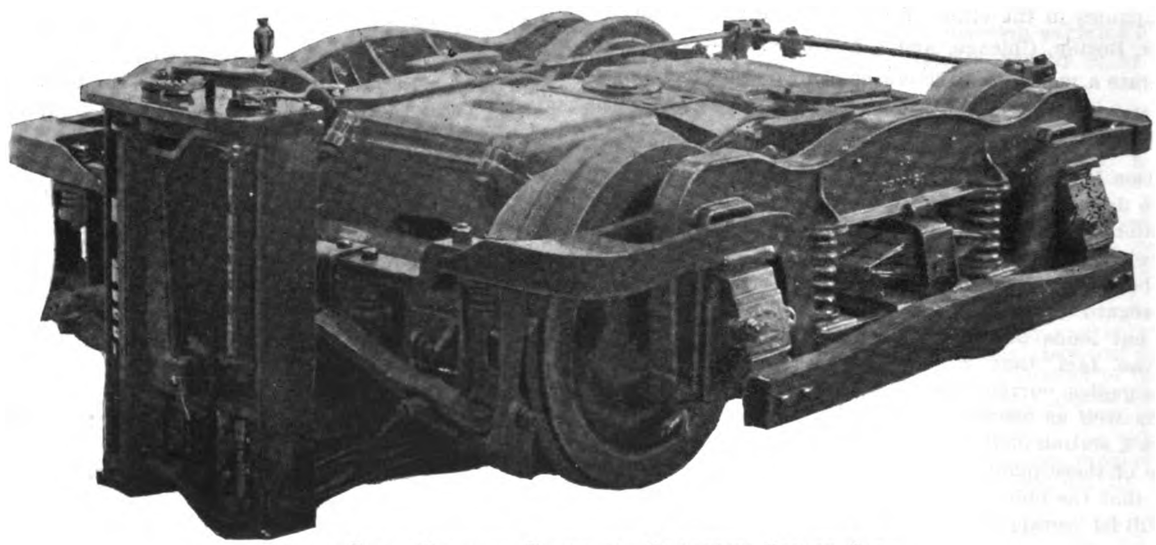

Fig. 1.—Fully Equipped Truck for Brooklyn Bridge Cars.

The motor cars do not differ outwardly from the regular passenger cars, except that the platforms are three inches longer. The length of the car is forty-five feet over all, and it weighs about twelve tons more than the ordinary car. The total weight with the motors is about thirty tons.

The trucks are from the shops of the McGuire Manufacturing Company of Chicago, and have been especially designed for this work. In these trucks the draft of the train is taken directly on the journal boxes, instead of through a swinging bolster, the entire top frame having a sufficient lateral motion to cushion on curves. The top frame is held in a central position in relation to the wheels by a novel double rocker connection between the trucks and the elliptical springs, part of the strength of these being utilized to cushion the side motion of the truck on curves, and return it to its normal position on the straight track. The weight of each truck is 10,000 pounds, wheel base 5 feet 6 inches, or 6 inches less than any other truck made for this purpose to accommodate two motors of the capacity of those used in this equipment. This is obtained by omitting the swinging bolster and substituting a better equivalent.

The general character of the electrical equipment is similar to that in use on the Metropolitan West Side and Lake Street Elevated Electric Railroads in Chicago, and on the electrically operated divisions of the New York, New Haven & Hartford Railroad. The equipment of each motor car consists of four G. E. 50 motors and two K. 14 series parallel controllers—motors and controllers also both especially designed to meet the peculiar requirements of the Bridge traffic. The motors have the usual characteristics of all General Electric railway motors. They are fully protected against the entrance of either dust or water, and for their power are extremely light, weighing each about 3,500 pounds. The armatures are of the slotted core type, each winding lying in its own slot. The

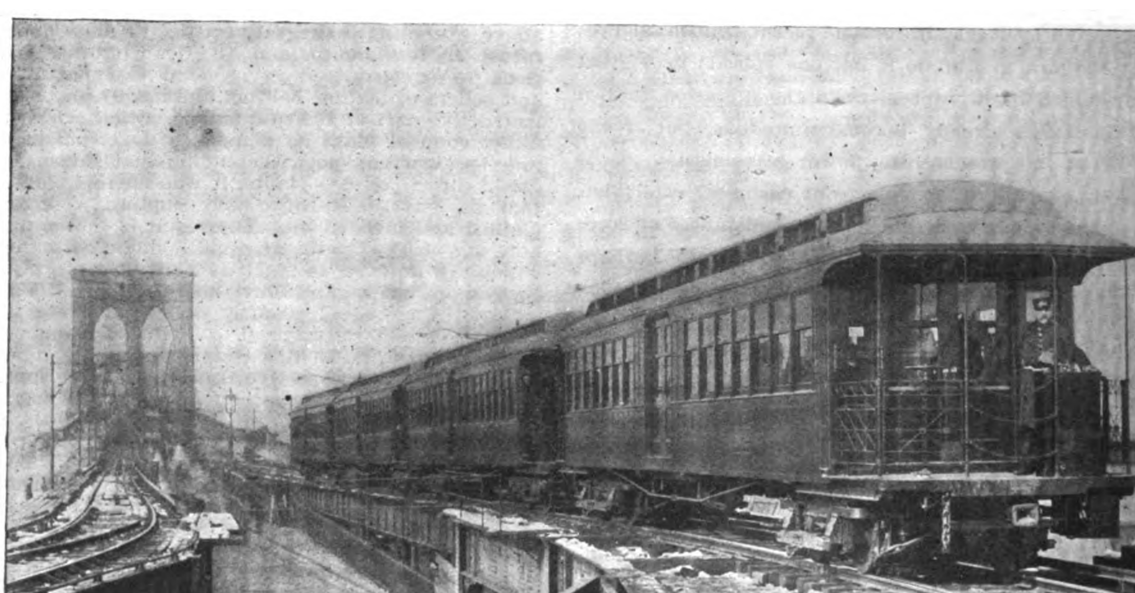

Fig. 2.—Motor Car Pushing Train Over Tilting Sheaves at the Brooklyn Terminal.

method of winding adopted allows of the removal and replacement of any of the armature coils with little or no disturbance of the others, while the crossing of two wires of large difference of potential is avoided. The motors are spring suspended, and the two forward ones are provided with a small roller at the front, upon which the cable can run and thus prevent injury to cable and motor. The illustration shows one truck of a motor car with a controller, and gives a fair idea of the compactness of the equipment. Each motor car has each track similarly equipped.

The series parallel controllers embody the magnetic blow-out principle, and in their operation, when the current is shut off, resistance is first introduced and the potential at the motor reduced before the circuit is broken. This avoids any strain on the motors due to sudden rupture of the current. When the circuit is broken the arc is immediately blown out, and the contacts do not suffer, the blow-out serving to chill the arc by spreading it over the surface of the breaking points instead of confining the root of the arc to its point of origin and consuming it.

The total number of notches is thirteen, six of the resistance points being in series and five in parallel. The reversing switch is, of course, arranged for four motors. The handle is interlocking and cannot be moved unless the controller handle points to the off position. The controller stands 46¾ inches high, 22¾ inches wide, and 10 inches broad, and is secured to the ironwork and floor of the platform. The resistances suspended beneath the cars are twelve in number. They are of the packed ribbon type set in open iron boxes.

Beneath each platform is an automatic circuit breaker, which effectually prevents any injury to the motors from a sudden rush of current. The breaker is set at 800 amperes, and should the current exceed this a latch is tripped by the action of a solenoid, and the contacts in the device are instantly separated, breaking the circuit. Additional protection is provided by cut-outs also embodying the magnetic blow-out principle, whereby the arc formed at the disruption of the fuse is magnetically extinguished.

The circuit breakers take the place of the well-known main circuit hood switches, and are wired in multiple instead of in series. In the experimental car to guard against any possibility of one being closed while the motorman was at the other end of the car and desired to open the main circuit, only one handle was provided. This handle could not be removed from the circuit breaker without breaking the main contacts, and when removed the circuit was locked open. In the new equipment no danger would ensue if both were thrown in, as the effect is simply to make the trolley connection alive on the controller, but the controller being open no current flows. In this respect the new equipment is superior to that used on the experimental car.

The current is taken from a third rail, in a manner similar to that used on the electric elevated roads in Chicago. This third rail runs on the outside of the service track and parallel with it across the Bridge and at all crossings and switches about one foot from the outside rail. The third rail used is the ordinary T-rail, bonded with No. 0000 bonds. They are laid on insulators, one of which is set at every fifth tie. These insulators are square, pyramidical pieces of vitrified clay, with a single petticoat, and are supported on iron pins fastened to the tie. The top of the pyramid carries two jaws, which grip the foot of the third rail and are screwed up by means of a bolt and nut. For the return the service rails are also bonded with No. 0 bonds. Between the journal boxes of each truck and on each side of it is an oak beam, from the center of which depends one of the contact shoes. These shoes are slung loosely from the jointed and slotted hangers, and have an easy up and down motion, as well as the ability to take any angle within a wide range, follow the surface of the rail at all times and make perfect contact. The shoes are of cast iron, about 12 inches long by 10 inches wide and ½ inch thick. Each weighs about ten pounds, and is wide enough to slide over all breaks on the third rail at all switches and crossings, and one shoe is always in contact. An insulated flexible cable connects the shoe to the motor.

The electrically equipped cars are known as the motor cars, and one is allotted to each train, forming part of it and carrying its share of the passengers. Its function is similar to that performed by the switching locomotives. The train empties at the terminal, the motor car draws or pushes it from the incoming platform to the tail track, and thence to the outgoing platform. It then moves the train over the tilting sheaves so that the grips on the other three cars may seize the cable, when the current is shut off and the cable performs its ordinary functions.

Under the conditions of the contract, the power of the four motors must be sufficient to propel the fully loaded train, weighing 120 tons, across the Bridge at the speed of the cable, 11.3 miles an hour, in case of breakdown of the cable. With the motors, the heaviest Bridge trains are readily hauled up the 3.78 per cent. grade, and so far as they are concerned, comply fully with the conditions. During the early morning hours the motor cars will handle the entire traffic of the Bridge after the cable has stopped running.

The motors will also help heavily loaded trains up the grades and keep the grips from slipping the cable. The substitution of the motor car eliminates one set of grips while adding twelve tons to the weight, and these grips are not always sufficient to handle trains which may be heavily loaded. As soon as the second set of tracks is ready and the additional cable running, it is expected that the headway will be reduced from 90 to 45 seconds.

The power to run the trains is taken from the Fulton street feeder from the Kent Avenue Station of the Brooklyn City Railway, the return wire being connected to the rails of the surface road.

The efficiency of the electric system under emergency was tested on the evening of December 2, 1896, when the operation was accidentally suspended. The rush homeward from New York to Brooklyn had already set in, and the entire operation of the Bridge for some half hour was thrown upon the motor cars. According to the Bridge authorities, the traffic was carried on without any appreciable loss of headway.

Roentgen Rays.

EXAMINATION OF CATHODE AND ROENTGEN RAYS THROUGH COLORED SCREENS BY THE FLUOROSCOPE.

BY JOHN CARBUTT.

1. The cathode rays in an excited Crookes tube viewed through a pale yellow screen, shows increased brightness of the yellow rays.

2. Viewed through a dark violet screen, the cathode rays present a phosphorescent glow, similar to that in a low volt lamp when held in the field of an induction coil.

3. Viewed through a green screen the cathode rays present to the eye a light emerald green.

4. Viewed through a dark red screen, the cathode rays present a pale red, on the carmine tint.

The screens are of thin polished plate glass 1½ m. m. thick, coated with gelatine, colored with aniline dyes, such as I use in making my photochromic screens.

Examination of Röntgen rays through plain glass and the afore-mentioned screens, shows that both cut off or absorb fully 50 per cent. of the Röntgen rays from reaching the screen of the fluoroscope. Screens of the following colors were placed side by side with the clear glass, viz., dark violet, green, light yellow and dark red, and when in juxtaposition, it was impossible to recognize which was clear glass and which was colored, and the eye was unable to detect any color sensation when looking through the fluoroscope with the colored screens in close contact.

These experiments confirm me in the opinion I have held from my first dealing with the Röntgen rays, that they are of the ultra ultra violet, because I find they absorb the entire spectrum, while a deep violet screen absorbs all but the red.

It was early determined by Prof. Röntgen that the X-rays could neither be deflected nor refracted, and I am not aware of any experiments having been made to determine the absorptive powers of the X-rays of the colors of the spectrum.

MR. EDISON'S X-RAYS EXPERIMENTS ON THE BLIND.

A LITTLE over a week ago the "Democrat and Chronicle," noticing that an editorial had appeared in our contemporary, the Rochester "Herald," giving Mr. Edison the credit of discovering that by means of the Röntgen ray some blind persons had been able to discern light, said that "Mr. Edison has laurels enough of his own without having those belonging to others placed upon his brow," and that "we don't think Mr. Edison would claim the credit of a discovery made by another man."

These remarks were based upon the fact that four days previously a dispatch had been received from San Francisco stating that Dr. G. Waverly Clark, a physician of that city, had made the discovery attributed to Mr. Edison. Our judgment was naturally confirmed by another dispatch sent out later to the effect that "Thomas A. Edison has verified the experi-

ments reported to have been made in San Francisco in which by means of a cathode ray a blind boy had been enabled to distinguish light."

It appears, however, from the following note from Mr. Edison that he is the original discoverer and that an article from him was in print before the San Francisco dispatch was published. The following is Mr. Edison's note, which we take pleasure in printing:

"Editor Rochester Democrat and Chronicle:

"Dear Sir: Article announcing discovery that a person blindfolded can see moving objects without the aid of a fluoroscope by the X-ray was sent to The Electrical Engineer, New York, and was in print before the San Francisco article was published there.

"I did not, however, experiment with blind persons. Nothing can be seen by the aid of the fluoroscope when one is blindfolded as stated in the San Francisco article, and there is good reason for the fact, because the X-ray, acting on the fluoroscope, is turned into ordinary light. The ray does not pass through to the eye. Last evening at the laboratory a child totally blind was made to see her hand and other objects by the X-ray, but nothing could be seen through the fluoroscope. It is difficult to imagine that the statement in the California paper is correct. Yours truly, THOMAS A. EDISON."

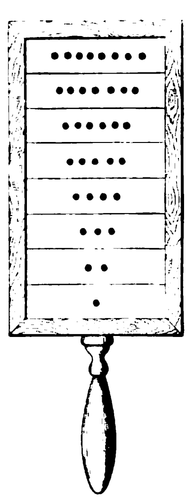
It is obvious from the above that Mr. Edison in this case, as in so many other inventions and discoveries, is the pioneer and entitled to the honors. The statement he makes in the note to this paper is of scientific interest in itself, not only in attesting the genuineness of his discovery, but in explaining the conditions of its successful application up to date.—Rochester (N. Y.) "Democrat and Chronicle."

A NEW X-RAY METER.

BY DR. F. S. KOLLE.

THE accompanying sketch represents a new X-ray meter, devised and used by me since November 12, with excellent results, being both handy, small and reliable.

It consists of a small mahogany frame and handle, grooved to contain eight sections of sheet aluminum, ranging from 1 to 12 mm. The sections have a consecutive number of holes drilled in them, filled with plugs of No. 8 lead wire, in such a way that No. 1 (1 mm.) upon being held in front of the fluoroscope and exposed to the ray emanations, a light area of cer-



KOLLE'S X-RAY METER.

tain dimensions and containing a black spot in its center, would be seen.

As the potential or tube efficiency is increased one section after another would become more or less transparent, all showing the dark spots, in the number corresponding to the plugs. No. 8 is 12 mm. thick and when perfectly transparent corresponds to an X-ray efficiency sufficient to make a radiogram of the adult chest and shoulders in from ten to eleven minutes, using the ordinary 60 sensito-meter dry plate and 10 to 12-inch spark coil.

The instrument can readily be made by any one, and can be adapted to suit its operator and apparatus. The quadrant of sections made by Reynolds and Branson, Leeds, is confusing, whereas in this instrument the operator does not stop to center the dots, as he becomes accustomed to the scale quite readily.

LETTERS TO THE EDITOR.

THERMO-ELECTRICITY HISTORY.

In 1801 it was noted by one Ritter that a current of electricity flowed in a wire when the two ends heated to different temperatures were pressed together. (Wiedemann, Vol. I., p. 627.)

Seebeck noted the same of two metals when one junction was heated. (Pogg. Ann. 1826.)

Magnus, in 1851, made further contributions to knowledge of the single metal current (Pogg. Ann. 1851), followed by Wiedemann, Becquerel, Matteucci and others.

Sir William Thomson in his Thermo-Dynamics gave mathematical and physical theories for the same. (See also Proceedings of R. S.)

Le Roux, in 1867, in a public lecture, showed an experiment with a sheet of copper, and a copper wire brought down to the same. This apparatus gave a current, and the lecturer drew attention to the part taken in the result produced by the oxide of copper at the end of the wire. (Ann. de Chim. et de Phys. 1867.)

In The Electrical Engineer of Aug. 5, 1896, Mr. C. J. Reed announces his new discovery of an electrical current produced by one metal, and so great is the importance of the discovery held to be that he coins a word for the name of the phenomenon, and the editor stands sponsor for the fact of the discovery, and suggests the possibility of utilizing the phenomenon for the purpose of obtaining current direct from coal.

Brooklyn, N. Y. HENRY D. HOOKER.

(The editor did nothing of the kind.—Eds. E. E.)

WANTED—A DEFINITION.

I should like to have a definition of the term thermo-electricity, as used by Mr. C. J. Reed in his article on the Jacques cell in your issue of December 2. My understanding of the term is, electrical energy developed by direct transformation of heat energy. If this is the meaning, then the fact that "the current obtained corresponds exactly to the electro-chemical equivalent of the carbon consumed and the carbonic dioxide produced" is proof positive that the action is not thermo-electric unless the e. m. f. of the cell is away below the theoretical e. m. f., which is not the case.

There is no avoiding the law of thermo-dynamics by transformation of heat into electrical, any more than by its transformation into other forms of energy, and if the energy of the carbon-oxygen separation were first transformed into heat and then from heat into electrical energy, only a small fraction of the total energy could be recovered, the balance going to heat up the cell.

If the electrical energy obtained from the Jacques cell is the equivalent or nearly the equivalent of the energy of the carbon consumed, it is proof that the energy of chemical separation of the carbon and oxygen is directly transformed in the cell into electrical energy.

New York, Dec. 2, 1896. WM. A. ANTHONY.

THE TRUTH ABOUT DR. LARDNER.

I find the following at the end of a paper on "Telephone Repeaters," by Mr. Thomas D. Lockwood, in the "Electrical World:"

"The versatile and brilliant writer and lecturer, Dionysius Lardner, while proving it to be absolutely impossible for any ship to carry coal sufficient in amount to enable it to cross the Atlantic by steam power, was confuted by the news that the feat had just been performed and that a steamer had arrived."

This statement has been disproved so many times, and it has been so long recognized as a baseless slur on the memory of one of the ablest popularizers of science who ever lived, that when Mr. Lockwood repeats it, it can only be inferred that he has found some new evidence to substantiate it; and I venture to express the hope that this will be soon forthcoming.

In the mean time, it may be pointed out that at the Bristol meeting of the British Association for August 25, 1837, at which it was alleged Dr. Lardner formally asserted the Atlantic steam voyage to be impracticable, two opposing projects then before the English public were under discussion; one being for a line of steamers between the west coast of Ireland and Boston, touching at Halifax; the other for a line direct between Bristol and New York. Lardner strongly favored the first and deprecated the second, because he believed that an unbroken voyage in the existing state of knowledge of steam engineering would not be found as profitable as one made in successive stages.

With singular prescience, he had added to the original sug-

gestion of the Boston-Halifax line the idea of a railway from the Irish terminus to Dublin, and steamers from Dublin to Liverpool connecting with the Liverpool, Birmingham and London Railway, so that the whole route, as he said, "would form one great continuous steam highway between the Capitals of the New and Old World." Such a line, he further insisted, would secure the contract for the British mails, the profits from which would counterbalance the losses due to lack of travel during the winter season.

When the discussion came up, Dr. Lardner said (London "Times" Report): "If there was one point in practice of a commercial nature which more than another required to be founded on experience, it was this one of extending steam navigation to voyages of extraordinary length." He was aware that since the question had arisen in that city it had been stated that his own opinion was adverse to it; that impression was wrong; but he did feel as steps have been taken to complete this experiment great care should be used in the adoption of means for carrying it into effect." Then he went on to advise the use of the best coal, to indicate what he thought the best ratio of power to tonnage, to recommend copper boilers, and the placing of coal in tanks, and finally, after more discussion, he reiterated that he "thought the voyage practicable, but he wished to point out that which would remove the possibility of a doubt, because if the first attempt failed, it would cast a damp upon the enterprise and prevent repetition of the attempt."

The charge which Mr. Lockwood repeats against Dr. Lardner had hardly gained publicity before it was immediately refuted, again and again in England, and later, in this country, when Dr. Lardner lectured here.

It was a suggestive example of the fate which is generally in store for the scientific person who dares to say what he believes, even if it be contrary to the interests of the promoters of an opposing scheme. The promoting tribe in 1837 was no different from its descendants of to-day, and it dealt with Dr. Lardner in that same kindly spirit, and with that perfect Christian consideration which has always characterized certain modern monopolies in dealing with those who have ventured to criticise either their alleged rights or wretched service.

New York, Dec. 2. PARK BENJAMIN.

TELEGRAPHIC STAGNATION AND ITS CAUSES.

In your issue of Oct. 21, you print an editorial headed "Telegraphic Stagnation," which shows that telegraphy is at a standstill without having recovered any of the eight million messages lost in 1894. In your issue of Nov. 18 you have an editorial with the caption, "The Decadence of the Manhattan Elevated," showing that this road has experienced a drop in its yearly traffic of 36,000,000 passengers since 1892.

It occurs to me that as both corporations are under the same control, like policies may have produced like results. The telegraph works with hand Morse, and the elevated burns cheap oil as an illuminant. The telegraph is in the semaphore stage, while the elevated is but an omnibus on stilts. To pay dividends by the "conservatism" found in both cases is like supporting one's self by chewing of gum. It would be better to be more radical and do some outside foraging. I am convinced that for progress it is unfortunate that telegraph managers ever knew the difference between a dot and a dash, or that an elevated railroad manager knows anything about steam. The telegraph manager hears his forty-dollar-a-month operator rushing fifteen words a minute over a five-hundred-mile line and knows by experience that this is the ultima Thule of efficiency. The railroad manager reveling in steam, smoke, cinders and grime frowns upon all electrical "experiments." Early training and a closed mind chain both to their idols for life. Li Hung Chang after his trip around the world found it irksome to hammer the ground with his head nine times on again approaching his exalted Emperor and was exiled from court for a year. Beware of innovations. PATRICK B. DELANY.

South Orange, N. J., Nov. 21, 1896.

SPEED INDICATOR FOR SHIPS.

The Electrical Engineer of Nov. 11 contains one of a series of admirable papers on "Electricity in Naval Life," by Lieut. Fiske, U. S. N., which treats of his speed indicator as used in the U. S. Navy. Some three years ago The Electrical Engineer described substantially the same thing as being my invention. In brief, the following language describes either designs; it is all a good electrical draughtsman would require to make working plans of such mechanism: "A direct connected alternate current generator of the inductor type secured to the driven shaft (the speed of which is to be indicated), in electrical connection with a meter whose dial is calibrated to read in distance units, instead of in volts or amperes."

As a matter of scientific interest, I might add I have gone further in the matter and developed recording mechanism which makes a chart of the engineer's speed at every moment of the voyage. JOHN C. HENRY.

Denver, Colo.

SOCIETY AND CLUB NOTES.

THE INSTITUTE TO DISCUSS THE THEORY OF THE ROENTGEN RAYS.

At the 111th meeting of the American Institute of Electrical Engineers, to be held at 12 West Thirty-first street, New York, Wednesday evening, December 16, a topical discussion will be held, devoted to a consideration of the relation of the Röntgen ray to physics. The discussion will be opened by Professor Rowland and Professor Elihu Thomson, Dr. M. I. Pupin, Dr. A. E. Kennelly, Mr. Osterberg and others have signified their intention to participate.

NEW YORK ELECTRICAL SOCIETY.

The 178th meeting of the society will be held at Columbia College, on Thursday, Dec. 10, at 8 p. m. The evening will be devoted to a demonstration of "How to Test the Commercial Efficiency of Dynamos and Motors," an entirely novel form of experimental lecture. A 3 horse-power dynamo and a 3 horse-power motor will be set up and tested in full view of the audience, by a special corps of experts. Professor F. B. Crocker will describe what is being done, and will make the actual tests; ex-President C. O. Mailloux will take the readings, and President C. E. Emery will record them on the blackboard. The audience will be informed of the reasons why each step is taken; will be able to see how the method of testing is conducted from stage to stage; will see the results placed on the diagram as soon as reached; and will thus enjoy a practical lesson in one of the most important branches of electrical engineering.

PERSONAL.

GEORGE W. BRECK.

The Jacob H. Lazarus scholarship, for the study of mural painting, was awarded last week to George W. Breck, president of the Art Students' League, this city. This scholarship entitles the holder to $1,000 a year for three years, and is paid by the treasurer of the Metropolitan Museum of Art. The successful competitor is obliged to spend these three years in study in Europe. Mr. Breck is about 30 years old. His home is in Washington, D. C. He has been a member of the Art Students' League since 1886,, and its president since 1894. The competitive drawings can be seen at No. 215 W. Fifty-seventh street. This success of Mr. Breck will greatly please his numerous electrical friends, to whom in days gone by his beautiful drawings of mechanical and electrical apparatus, many of which have adorned the Engineer, were a constant delight. He is a genuine and broad talented artist.

MR. C. R. FISH, who has for the past three years been general manager of the Suburban Light and Power Company, Boston, has resigned that position and has accepted a position of salesman under Mr. E. I. Garfield, manager of the New England department of the Fort Wayne Electric Corporation. Mr. Fish is well known in the East, and should make a valuable acquisition to Mr. Garfield's staff.

OBITUARY.

F. G. PRATT.

We regret to announce the death of F. G. Pratt, of the General Electric Company, which occurred November 7 last. Mr. Pratt was born at Keene, N. H., and graduating from the grammar and high schools of that town, entered Harvard. After taking his degree with honors with the class of '84, he returned to Keene, and became sub-principal in the High School in which he had received his early education. This post he filled for three years. He then became idenified with the Boston and Albany Railroad in the office of the Electrical

Superintendent, but his health failing he accepted a position with a suburban railroad, for which he did considerable surveying work. His experience in railroad operation opened up for him a position in the Union Switch and Signal Company. While with this company he invented and patented several valuable devices. In 1892 he entered the employ of the General Electric Company, and shortly afterward took entire charge of the catalogue department of that company. His special aptitudes and the breadth of his technical knowledge, extending as it did not only into the purely catalogue work, but also over the patent and engineering branches of the electrical business, adapted him peculiarly to the duties which fell to him.

Any one acquainted with the vast amount and variety of the printed matter and special information which the operation of such a large company necessitates, and the perfect shape in which it issues from the press will realize the responsibility which rested on Mr. Pratt's shoulders. Mr. Pratt was only thirty-six years of age at the time of his death. He was universally esteemed, and his death will be a source of regret to all who knew him.

MR. C. BAYLISS.—A dispatch of Dec. 2, from Mount Clemens, Mich., says: "Charles Bayliss, manager of the Mount Clemens and Lakeside Traction Company, committed suicide by shooting himself through the heart in his room at the Avery House this afternoon. Bayliss was thirty-two years old and came from Pittsburg six months ago. Family troubles and temporary insanity are the causes alleged for the act."

POWER TRANSMISSION.

CARD MOTORS DRIVING MACHINE TOOLS IN THE PATERSON STATION.

WE show in the accompanying illustrations several admirable examples of direct connected motors operating machine tools now running in the splendid station of the Edison Electric Illuminating Company, at Paterson. These consist of a Smith & Mills 20-inch crank shaper, Fig. 1, the motor operating it running at from 100 to 400 revolutions per minute.

In the Prentice drill, shown in Fig. 2, the speed of the motor is constant and the adjustments are obtained by utilizing the cones already provided for the press; the driving-head is at the

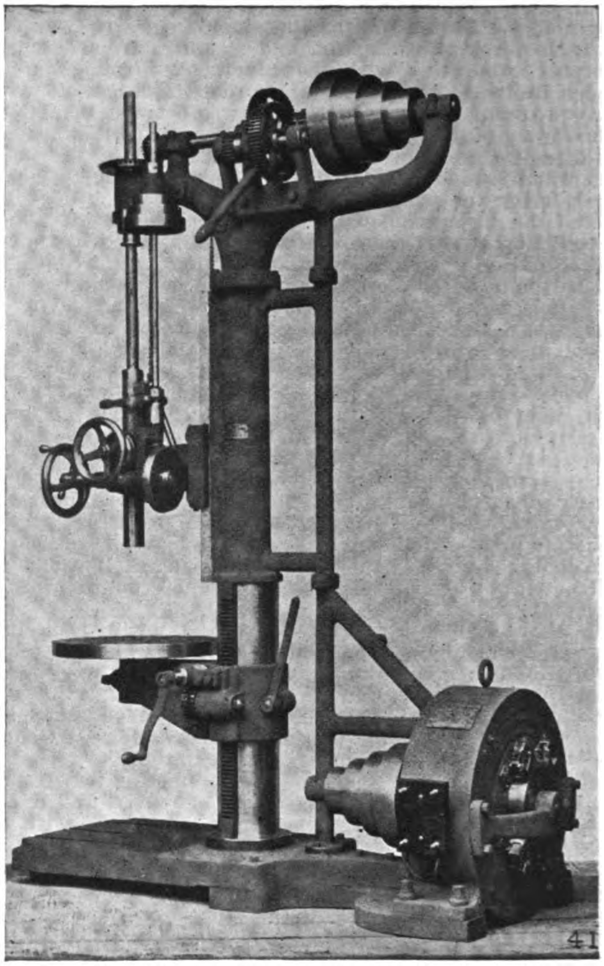


FIG. 2 —DRILL PRESS DIRECT DRIVEN BY CARD MOTOR.

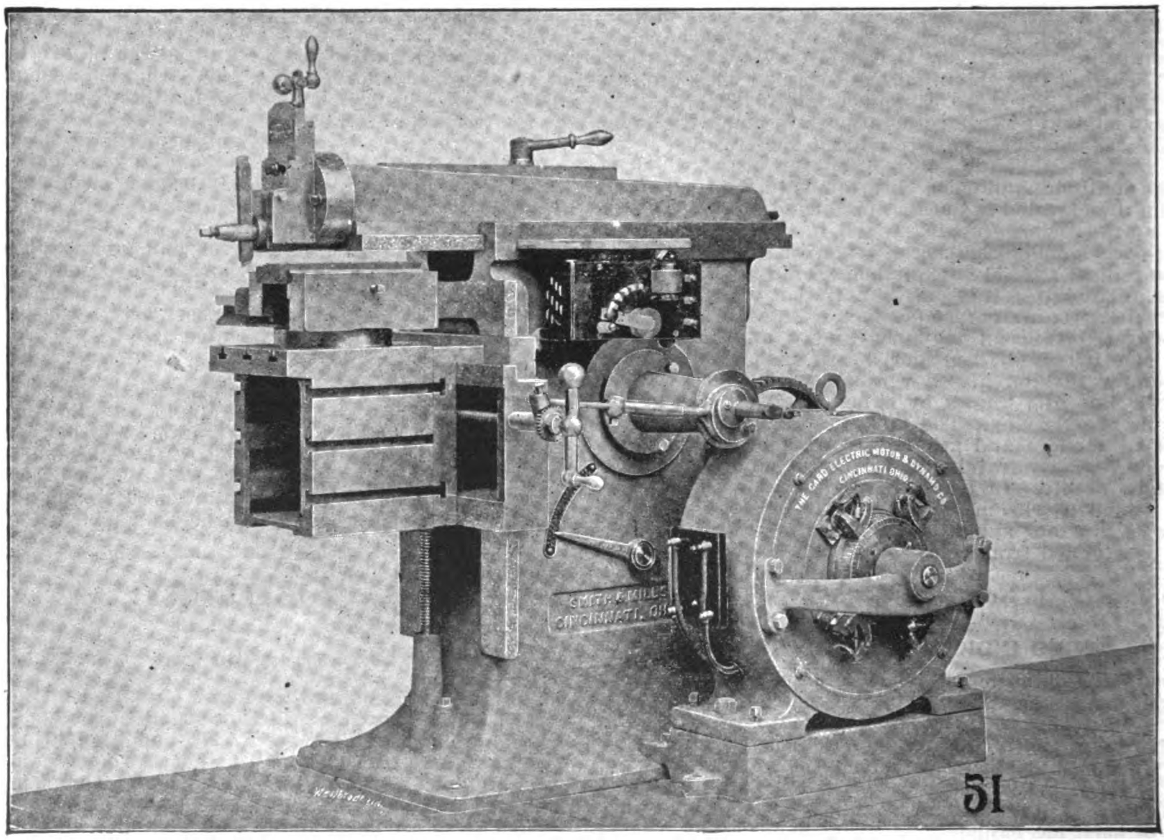

FIG. 1.—SHAPER DIRECT DRIVEN BY CARD MOTOR, PATERSON EDISON STATION.

top of the press; this arrangement proved to be the best balanced one and well suited to the general design of the tool.

In addition to these tools there has been supplied a 24-inch lathe, similar to that shown in our advertising pages, with the motor built in the head stock in place of the usual belted cones, and a 14-inch emery wheel, consisting of a motor carrying the wheels at either end of the shaft extension. These tools are of special interest, because of the fact that the motors are placed direct on their driving shafts.

The Card Electric Motor and Dynamo Company, of Cincinnati, who have supplied all these motors, have in the past two years fully developed the slow speed motor for direct driving, and lay claim to being the pioneers in this field.

MECHANICAL.

COOLING CONDENSING WATER BY AIR VAPOR ABSORPTION.

BY EDWARD F. WHITE, M. E.

WITHIN the past five years marked advance has been made in the method of employing the cooling effects of "air-vapor-absorption," under conditions of induced air circulation over an extensive water surface.

There are at the present time several different designs of apparatus in use, cooling for re-use the heated circulating water from steam engine condensers, the operation of which coolers depends upon the above action.

The accompanying engraving represents one particular form of water cooler, in connection with which an extensive line of experimental tests were lately made at the Stevens Institute of Technology, Hoboken, N. J., to verify the degree of accuracy in the estimated relative proportions, that is, area of

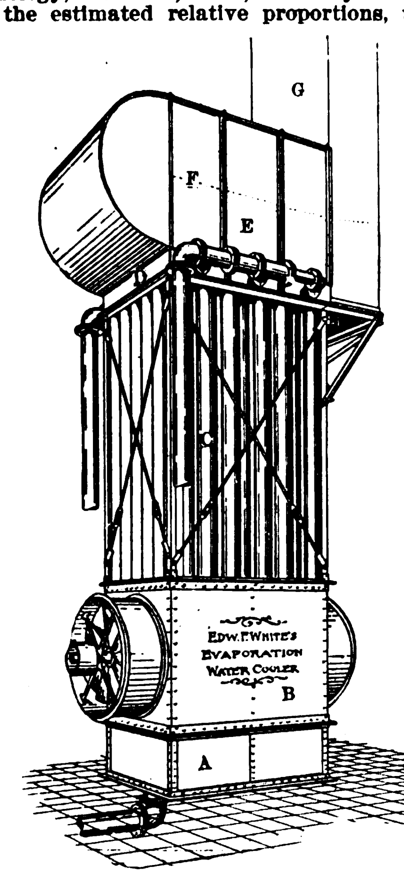

FIG. 1.—WHITE'S EVAPORATION WATER COOLER.

cooling surface, volume of air, weight of evaporation water, degree of cooling action, temperature limits, quantity of water cooled, etc., and to establish a unit line upon which to base capacity estimates for this apparatus.

I believe some of the results obtained will be of interest to the readers of The Electrical Engineer, because little, if any, information based upon actual experiment in this line has been published. In fact, the writer was led somewhat astray by various statements from apparently good authority, made, however, with reference to matters foreign to the subject in hand, which statements I now believe to be incorrect.

For example, it has been stated that "at best, as a carrier of moisture, hot air cannot in practice be charged beyond half its full saturation." This conclusion was arrived at, I believe, by experiments with hot air drying chambers. Another authority records the proposition that "the rapidity of evaporation is the same whatever may be the temperature of the air." That water is evaporated more rapidly when a current of warm air blows over it than when it is traversed by a cold current is a fact that has been noted by engineers operating steam plants condensing by means of evaporation cooling, the record being that "a better vacuum is kept on warm summer days with a fresh breeze blowing than on a cold day with but slight air movements." This is doubtless due, at least in part, to a more rapid removal of vapor by an atmosphere whose capacity for moisture is much increased, due to the higher temperature, and possibly also, in some cases, to the effect of warm air upon the water surface, raising its temperature and thereby diminishing its internal pressure so-called, or its tendency to vaporize on the warm summer day, which is not the case in cold weather.

Before the apparatus was in shape numerous experiments, and notable changes, very considerably modified the ideal condition originally assumed and proportionately the anticipated results.

The four tests recorded in the following table are arranged in the order of increasing temperatures of fan exhaust, and decreasing volumes of circulating water, under which conditions a fairly uniform rate of steam condensation seems to have been maintained of about 173 pounds per hour from temperature corresponding to 4 pounds gauge, to water at 125 degrees F.; while for the high temperatures of fair exhaust (and consequently of circulating water) the vacuum fell proportionately:

Extract of test: White's Combined or Self-Cooling Surface Condenser.

Number of test.	4.	8.	5.	9.	Average.
(1). Square feet evaporating surface per pound of steam condensed per hour, equiv. (4 pound gauge, to 125 degrees F)	.28	.308	.258	.257	0.27
(2). Pounds evaporation per pound steam condensed; equiv. (4 pounds gauge pressure to 125 degrees F.)	1.04	1.07	1.0	.98	1.02
(3). Cubic feet fan exhaust per pound steam condensed (4 pounds gauge p. to 125 degrees F.)..	300	208	204	175	222
(4). Efficiency of cooling action equal to B. T. U. steam condensed, divided by B. T. U., corresponding to vapor absorbed	75%	82%	80%	82%	80%
(5). Final temperature fan exhaust	110°	122°	124°	129°	121°
(6). Pounds circulating water per pound steam condensed (4 pound gauge at 125 degrees F.)	61.7	55.	39.5	39.	49.
(7). Average vacuum—					
Mercury col...........	24.	22.6	20.9	21.	22.
Due to temp. hot well.	24.3	25.8	20.4	20.	22.6

During the entire series of tests the indicated horse-power required to drive the fan was about constant, while the power to drive the pump of course varied in proportion to the quantity of water delivered. This total power, under conditions of maximum duty, was about 6 per cent. of the power represented by the steam condensed, handled, taken at 18 pounds per horse-power per hour.

Both the fan and the pump in this case were at a decided disadvantage, due to necessary local arrangements, and it is fair to say consumed in the amount stated double what would have been required under ordinary good conditions.

It will be noticed that the feature of this apparatus consists of a construction based upon positive unit measurements of the effective cooling or evaporating surface, the accuracy of which unit appears from the uniform results—see (1) in table—obtained in the conditions of a saturated fan exhaust, and, consequently small volume of same per pound of steam condensed—see (3). (Note.—The excessive quantity of evaporation water was not due to entrained moisture lost, but to mechanical losses in the connection, etc., which amounted to about 7 per cent. This however, is included in the weights recorded, and, therefore, affects the results unfavorably to that extent).

By careful hydrometric and temperature tests of the escaping fan atmosphere, it was determined that in a tin pipe ex-

haust leader of the same size as the fan opening, the temperature of escaping vapors fell approximately 1 degree F. for each foot of pipe length. In other words, by carrying the fan exhaust in a vertical thin metal pipe out of doors to a height of about fifty feet, from 60 to 90 per cent. of the absorbed moisture may be recovered as pure water for boiler purposes independent of oily hot well discharge, which latter may be turned into the circulating water tank, where the grease can do no harm; in fact, where the grease will be largely separated by decantation or overflow from the cistern. Finally the air circulation was induced by an exhaust fan instead of blowing, as would be the case in the arrangement shown in the illustration. Theoretically, the decreased resistance in the fan (due to the comparatively low density of the saturated warm vapor) would be offset by the increased volume of discharge over and above that at the initial temperature of the air. But of the fact that the high degree of saturation, as also the ample air circulation obtained, were largely due to this arrangement there is no doubt, thus directly increasing the efficiency of the cooler.

The following is a description of the cooler shown in the engraving. The apparatus tested being an element (single) of this arrangement. The essential parts are the foot tank A, fan-box B, concentric cooling tube systems or element C, and the water disturbing box D, containing the heads, and the hood-stack connection E. The hot water enters through the box D, the several cooling tube systems at the top, and by means of the specially devised distributing heads, is sent down

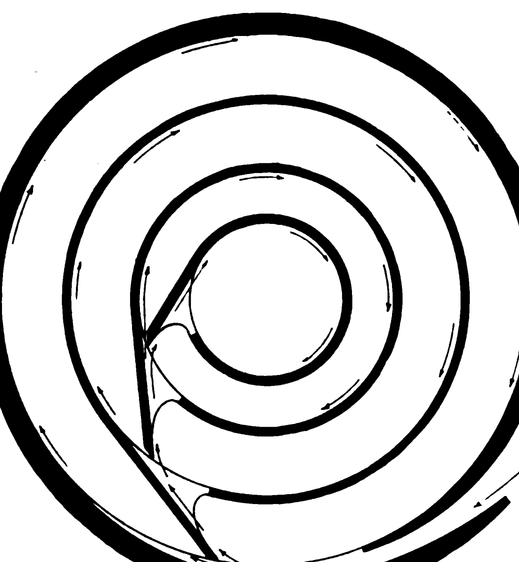

Fig. 2.—White's Evaporation Water Cooler.

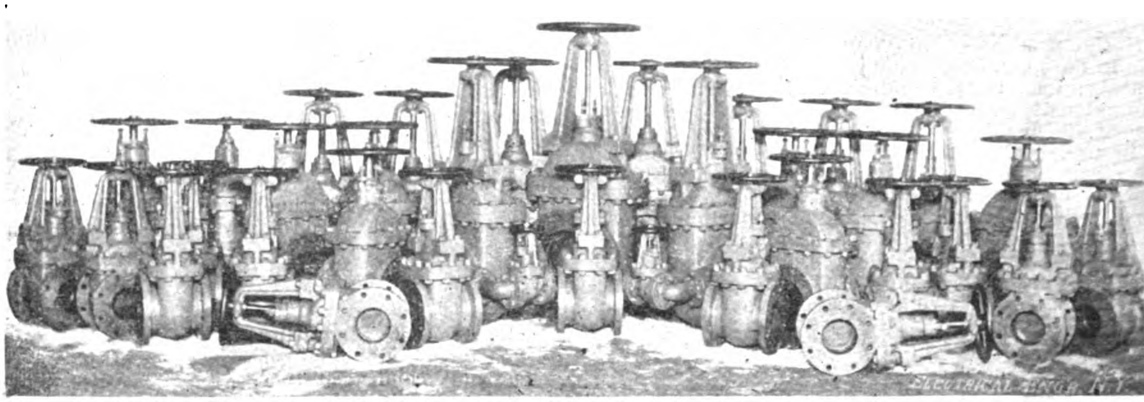
spirally along the inside surfaceof the tube, Fig. 2, the volume of which tube forms a straight smooth passageway for the air current. By means of the hood E any entrained water is separated by the baffle plate F, while the water settling from the cooling vapors as they escape through the stack G finds its way back to the cooler and cisterns below, or may be collected at the stack base and used separately as pure water. By placing the fan at the hood and stack junction the headroom of the cooler would be lessened by the height of the fan-box; the space below, in that case, would be done away with.

The construction of this apparatus is almost entirely of riveted leader pipe, galvanized. The tank below shown, of ordinary tank iron, would, if the cooler were located on the ground, naturally be a masonry pit. It need hardly be stated that the exposed position of the cooling tubes adds very largely to the effectiveness of the apparatus.

THE EATON, COLE & BURNHAM CO'S VALVES.

ELSEWHERE in this issue, in an article descriptive of the new station of the Edison Electric Illuminating Company, of Paterson, N. J., mention is made of the valves used in the construction and operation of the plant. More extended notice than could be accorded them in that article seems to be deserved.



Eaton, Cole & Burnham Co.'s Steam Valves Furnished to the Paterson Electric Illuminating Co.

Through the courtesy of the Eaton, Cole & Burnham Company, who are manufacturers of the appliances mentioned, we are enabled to present to our readers an illustration of a portion of the valves which are in use in operating the plant. As will be seen in the accompanying engraving a great variety of sizes and designs enter into the application of these valves to the purposes for which they are used, and to the duty they have to perform.

In constructing valves for the high pressures which are involved in running the engines of electric plants, great care is necessary in selecting the material from which the various parts are to be made. Not only is a great strain upon the material to be provided for, in consequence of the high pressure of steam, often superheated, but expansion and contraction in the lines must be considered; this is true not only of the valves but of the numerous fittings of differing shapes which are required for branching lines, turning corners, etc. In the plant in question each part or piece was designed with reference to the requirement of the place in which it was to be used, and although these fittings are not shown in the cut they were manufactured by the same company.

The high pressures, to which we have alluded, make necessary quite frequent renewal of packings about the various movable parts of the valves, and this must quite generally be performed while the steam is running through the valves. A very efficient device to admit of this repacking under pressure has been placed in these valves and overcomes what otherwise might prove to be a serious inconvenience in the continuous operation of the plant.

As an indication of the mass of material used in the construction of electric plants, it may be mentioned that simply the group of valves illustrated, and which form by no means a large part of the outfit, amounted to a large carload both in volume and weight.

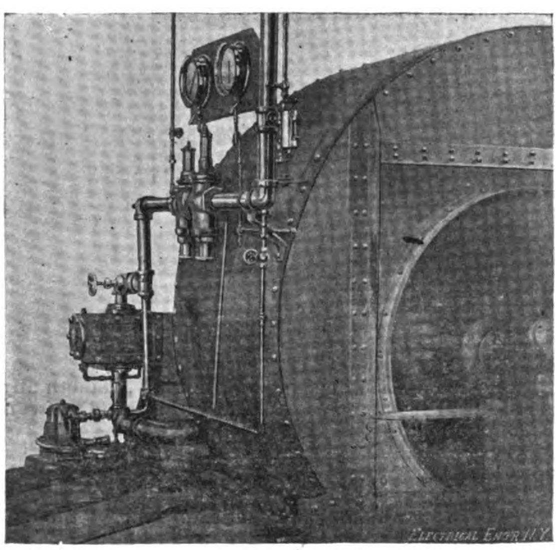
THE BECKMAN SYSTEM OF AUTOMATIC FORCED DRAFT REGULATION.

IT is an acknowledged fact that the more even the pressure on a boiler can be maintained, other things being equal, the greater will be the economy in coal consumption. Indeed, an even pressure card is prima facie evidence of a well-fired boiler. But even with the most experienced and careful firemen considerable variations will occur and hence an apparatus which makes the maintenance of proper pressure inde-

pendent of the fireman is evidently of great value. This was recognized when the new station of the Edison Electric Illuminating Company, of Paterson, which is described elsewhere in this issue, was designed with the result that the Beckman system of undergrate forced draft regulation was installed in connection with fan blowers.

The Beckman system, which is illustrated in the accompanying engraving, consists of a simple arrangement of three moving valves placed as a unit in the steam pipe to the engine driving the fan. These have no more moving parts and are sure to drive the fan at the highest speed to produce the necessary quantity and pressure of air for burning the fuel at its maximum efficiency and producing the greatest heat under the boiler that the water is capable of absorbing. The stack damper is set to hold back this heat so that the escaping gases do not leave the uptake at a temperature much above the temair to keep the grates cool and the fires bright. When the steam pressure in the boiler has reached the desired point, the regulating valve cuts off the direct supply of steam to the fan engine, and would stop the fan, but for the introduction of a by-pass having a reducing valve introduced in its line which furnishes just sufficient steam at a very low pressure, from 5 to 8 lbs. This keeps the fan revolving, supplying enough air to keep the grates col and the fires bright. When the steam pressure falls two or three pounds, the regulating valve opens and steam is admitted to the fan engine, which immediately furnishes air to burn the coal fast enough to restore the desired pressure.

The fireman does not have to watch or adjust any valves or dampers, but can give his undivided attention to keeping a sufficient amount of coal on the grates, either by hand firing or



THE BECKMAN SYSTEM OF FORCED DRAFT REGULATION.

mechanical appliances. Fine coal and even coal dust, can be burned economically by this system. There are as many British thermal units in a pound of coal dust as in an equal weight of lump coal; the difficulty has been to get air through a mixture of this kind, fast enough to make steam, the tendency being for it to lie on the grate bars baking and distilling Having a fan automatically controlled to furnish the proper amount of air at the proper time and pressure, this cheaper fuel can be burned fast enough to produce steam at a very marked difference in cost. This saving in cost has been in one case, 50 per cent., owing largely to the inefficiency of natural draft to furnish sufficient air to burn even a high grade of coal.

The system illustrated was installed in the Paterson Edison station by the Kensington Engine Works, of Philadelphia, and has already been applied in a number of other central stations and large power plants.

MR. KNUTE O. HAGEN writes us from Iowa: "I have now been taking your paper nearly a year and I am glad to say that I am very much pleased with it. I have some other papers, too, on the same subject, but I consider yours the best of them all."

MR. H. C. TOWNSEND, the well known patent attorney, is the subject of an illustrated biographical sketch in the "Banking and Law Journal" for October.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

AFTER THE BERLINER DECISION, WHAT?

"The Electrical World" contained an article from the pen of Mr. E. L. Frost, with reference to the Berliner case at Washington, and its conclusions are apt to lead the public into a fear that the Berliner patent is to be sustained sufficiently to prevent the use of telephone instruments of the Microphone type.

The writer has followed the Government cases carefully, from the beginning, and listened attentively to the arguments before the Supreme Court. The labored and flowered ordeals of the Bell counsel might indicate, to an ordinary listener, abundance of advantage. The records and briefs, however, appeal to the writer as having sufficient meat to make a much stronger case for the Government than appears from the oral arguments. The Supreme Court is more apt to be guided by the printed briefs and records than by the flowery or labored speeches of either side.

However, the thing which most struck the writer was the interest shown, at times, by the Supreme Court Justices sitting in the case. Justice White, interrupting the Bell counsel, asked: "Do we understand that the Berliner patent en suite covers the Blake transmitter?" Mr. Fish replied: "Yes, sir, it covers all forms of microphones." Then Justice White asked: "Do I understand also that the Blake transmitter has been in use by the Bell Company for over eighteen years?" Mr. Fish flushed and stammeringly replied affirmatively, while the entire courtroom, including the Justices on the Bench, seemed to feel the significance of the questions and answers, as Justice White leaned back and said, "Very well, very well," and Justice Harlan plainly acknowledged acquiescence. This, together with several questions asked by the Justices, were leading to the impression that the Supreme Court was getting into the case deeper than the oral arguments.

The writer's opinion is that the Supreme Court will be divided; that not less than four Judges a majority of those sitting, will be of opinion that the Berliner patent should not be sustained sufficiently to be dangerous; that others may be affected by legal technicalities, which did not strike Judge Carpenter as sufficient.

However, the public need not conclude that the action of the Supreme Court in this Government case is so far-reaching that microphone transmitters may be monopolized by the American Bell Telephone Company. There are a great many defenses to the Berliner patent not raised in the Government case. In fact, evidence is at hand which will absolutely show the patent to be worthless, and it may be added that no intimation of this evidence appears yet to have discovered itself outside of the channels controlled by the Western Telephone Construction Company. Perhaps the writer is mistaken, and that "history will repeat itself." It is possible that the Bell Company also knows of this evidence, and are attempting to quietly "work the courts," through the Berliner patent in some such manner as they attempted to "work the courts" upon the Watson patent, until we suddenly terminated it.

The writer desires to assure the public that in case of suit upon the Berliner patent against the Western Telephone Construction Company, or its patrons, the Berliner patent will be defeated without question, and in much simpler and shorter order than Mr. Frost's article would seem to indicate.

J. E. KEELYN,
President Western Telephone Construction Company.

THE BRYANT ELECTRIC CO. BRANCHING OUT.

The Western supply trade will note with interest the establishment of a branch factory at East Liverpool, Ohio, by the Bryant Electric Company, manufacturers of the well known "Bryant specialties." The Bryant Company state that it is not their intention to manufacture their complete line of supplies at East Liverpool, but for the present will confine their work at that point to Sawyer-Man cut-outs, 500-volt railway blocks, and the well-known K. W. ceiling rosettes, and that the manufacture of other specialties will be added as necessity demands.

The largely increasing Western trade of this company has made necessary the move outlined and the advantages resulting to the supply trade in the way of early deliveries and reduced freight rates are very apparent. The Bryant Company

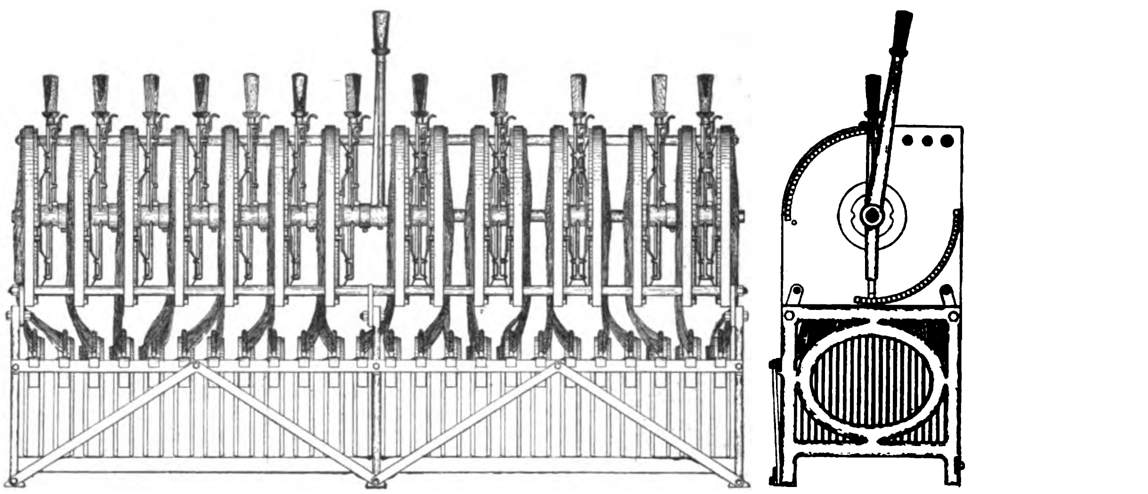
will establish no business office at East Liverpool, and all correspondence should be addressed as formerly, either to their Western office at Chicago, or the main office at Bridgeport, Conn.

IRON CLAD THEATRE DIMMERS.

THE progress of theatre lighting and the control of electric light for scenic effects is of interest alike to the theatrical profession and to the constructors of theatre lighting plants.

The Iron Clad Rheostat Company of Westfield, N. J., are leaders in improvements in theatre dimmers, and among the recent improvements made by them is an interlocking switch system. Where several dimmers are used, a system of interlocking the switch handles, so that any or all of the dimmers can be operated by one central master bar, is indispensable. The long experience of the Iron Clad Rheostat Company in the manufacture of theatre dimmers, and the success they have met in all classes of this work assures intending purchasers of desirable results. Where particularly fine effects are desired this style of theatre dimmer meets all the requirements.

The bank of theatre dimmers illustrated herewith was built for one of the largest theatres in the country. It is composed of four 3-wire dimmers and eight 2-wire dimmers, ranging in capacity from 40 lights to 200 lights each, a total of 1,150 lights; dimensions 78x37x20 inches exclusive of handles. The completed instrument is very neat, compact and substantial, and fulfills the specifications of fire departments and insurance underwriters.



Iron Clad Rheostat Co.'s New Theatre Dimmer.

In addition to the above described large bank of dimmers, this company recently filled an order for a bank of 24 dimmers complete with interlocking switches. This bank has a capacity of 1,480 lights; dimensions, 120x37x20 inches exclusive of handles. The maximum height to the top of the master bar is 48½ inches.

The several styles of iron clad dimmers cover all possible applications. Dimmers of any capacity from one light to 10,000 lights, in any of a dozen different styles, can be furnished by this company promptly.

THE KENT LUBRICATING COMPOUND.

It is a great comfort to operators of machinery plants to know that the apparatus is well constructed and reliable; but not less ease-giving is the assurance that such apparatus is properly handled and maintained in condition such that its life shall be prolonged and the cost of its operation reduced to a minimum. The cost of work lost in friction and repairs due to the heat generated thereby in machinery is being more and more appreciated by intelligent power users, with the result that the matter of lubrication is receiving its due share of attention, for upon it the life and the economy of machinery largely depend.

In the magnificent station of the Paterson Edison station, illustrated elsewhere in this issue, particular attention has been paid to this point, and as in all the other parts of the equipment and operating accessories, only the very best is employed. To meet the high ideals of the company, the Kent lubricating compound is regularly employed. This compound is largely composed of light mineral oil, chemically united with tallow, giving it the requisite viscosity and softness, and yet requiring a temperature of 350 degrees Fahrenheit to melt it. The result is that the compound does not melt, but stays where it is needed—at the wearing surface. This also means that it is a much cleaner lubricant than the usual oils, the drip from which soon gives most engine rooms an unsavory appearance.

The N. Y. and N. J. Lubricant Company, 30 Cortlandt street, manufacturers of the Kent lubricating compound, issue a neat little pamphlet, showing the best methods of applying the Kent lubricant to bearing surfaces of various kinds. The pamphlet also contains a large number of the most appreciative testimonials from some of the largest power users in the country, as to the value of the compound, and if only half of what is said of it is true, it ought to find a place in every engine and dynamo room.

A NEAT AND USEFUL SOUVENIR.

One of the neatest and most useful little souvenirs that we have yet seen given out by electrical supply houses, has just been perfected by Mr. Hugo Reisinger, of New York City, who, as every one knows, imports the "Electra" carbons. The souvenir is a caliper measure for accurately ascertaining the diameter of carbons, the graduations being marked in inches and millimeters. The measure is made of fine wavy cameo, direct from Paris, and reflects great credit in Mr. Reisinger's judgment and taste. They are at present being presented to Mr. Reisinger's customers, but as they are of considerable value will not be distributed indiscriminately, though any user of carbons desiring a measure of accurate quality would do well to communicate with Mr. Reisinger.

A LIGHTING PARADOX.—OPEN vs. ENCLOSED ARC.

WHENEVER an attempt is made to express the value of the illuminating power of a source of light by designating its candle-power, the result is never a true value of the power of the light. This is because the measurement of candle-power may be the same for lights of widely different qualities. The eye is a much better instrument than the photometer for arriving at an approximate value of the true illumination, because the eye takes quality of light into account as well as mere candle-power. But even the eye is sometimes deceived. As an instance of such deception the following test is interesting.

An inclosed arc lamp and an open lamp were placed side by side for comparative test in a large commission house in New York. The test was made in the afternoon, before the sun had gotten well on the horizon; a number of the members of the concern acted as judges of the lights, and decided almost unanimously in favor of the open arc. When darkness set in another test was made, and the same judges, without exception, unhesitatingly gave the preference to the inclosed arc. Whereas, in the daytime the inclosed arc appeared dimmer than the open arc, after dark the reverse was the case.

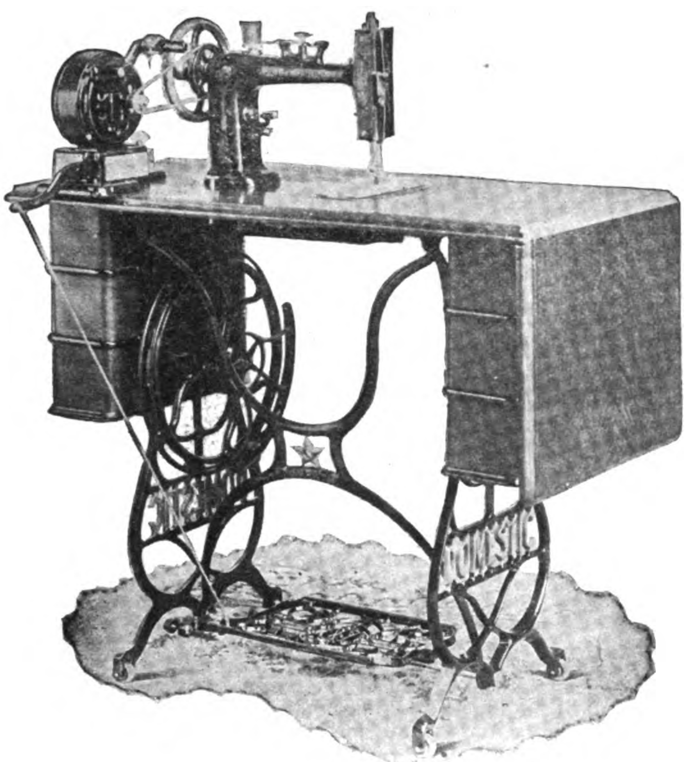
At first sight this seems paradoxical, but the explanation is quite simple. The quality of light rays emanating from the "Pioneer" lamp, which is the inclosed arc above referred to, approaches so closely that of daylight that during the daytime the light of this lamp appears dim compared with the light of an open lamp, whose quality is radically different than that of the sunlight; and, by virtually taking the place of daylight the inclosed arc is actually much brighter than the other lamp, and appears so to the eye. Compared with the "Pioneer" inclosed arc under these conditions the open lamp looks yellow and dim.

The only time to get a practical measure of the value of the light is when darkness sets in. That is when the light is used, and that is when it should be measured. The second test alluded to above was naturally the one to which most importance was attached, and resulted in a signal victory for the "Pioneer" inclosed arc. It is safe to say that in the majority of cases, especially where proper quality of light is necessary, this lamp affords an almost perfect substitute for daylight.

THE KENT ALTERNATING SEWING MACHINE MOTOR.

The extended use of the alternating system of electric lighting has created a large demand for small power specialties for such circuits. The Kent Electric Manufacturing Company, of Worcester, Mass., have lately been bending their energies in this direction, and one of their results is a sewing machine motor illustrated in the accompanying engraving.

The great difficulties encountered in this work are the small starting torque, and the non-variable speed of these motors. Both of these obstacles are overcome in the device shown. The motor, which is of the induction type, is mounted on a base, to move with a lever, connected to the treadle of the machine, and the speed regulation is obtained by tightening and slackening the belt. By this method, any desired speed may



The Kent Alternating Sewing Machine Motor.

be maintained. In this way even more perfect regulation can be obtained than by direct current, as the speed can be changed in an instant, and the brake which touches on the circumference of the balance wheel stops the machine instantly.

A switch located on the base is turned on when the operator sits down to the machine. The motor is thus started without a load, and is running constantly while the machine is in use. It is compact, and neat in appearance.

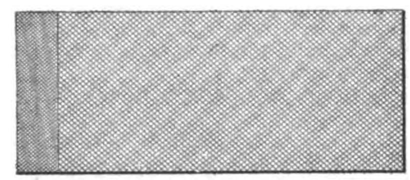
The company also manufacture a variety of other apparatus such as battery fan outfits, alternating current fans, and small machines which can be run either as a dynamo or a motor, capable of lighting from one to four 8 candle-power lamps, or of running a 6-inch fan. The voltage varies with the speed from 1 to 18 volts.

LARGE ADDITION TO THE ANSONIA ELECTRICAL CO'S FACTORY.

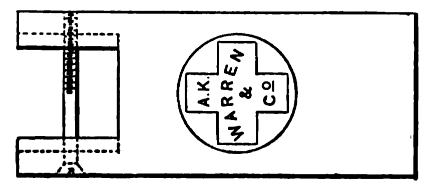
Mr. Thomas Wallace, Jr., vice-president and manager of the Ansonia Electrical Company, of Ansonia, Conn., writes us that they have placed the contract for a three-story addition to their factory. It will be 40 feet by 90, and is already in course of construction. They expect to have it ready for occupancy by January 1, 1897. It will be used to take care of the increased demand for the company's well-known lines of goods, as they do not contemplate at present going into any new branch.

THE WARREN BRUSH EXTENSION.

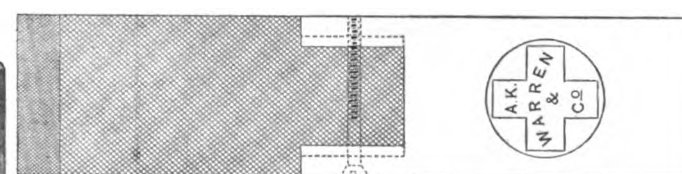
A not inconsiderable expense attached to the operation of dynamos is the cost of brushes, especially where gauze brushes are employed. With the usual form of brush holder the stump remaining is rarely less than two inches in length which means a waste of anywhere from 25 to 50 per cent. of the original cost. An ingenious device for reducing this waste almost entirely is the brush extension manufactured by A. K.



ORDINARY WASTE.



EXTENSION.



COMBINATION.

Figs. 1, 2 and 3.—The Warren Commutator Brush Extension.

Warren & Co., of 451 and 453 Greenwich street, New York. The accompanying engravings showing the device are almost self-explanatory. The brush, as will be seen, has an offset a little over one-half inch in length, which is slipped into an extension socket and secured by a screw passing through both. The whole costs no more than the usual brush, and the device can be used on all kinds of brushes. Old brushes can also be made to fit the extension.

ERICSSON TELEPHONES IN NEW YORK.

Among the recent contracts secured by the Wilson-Bates Electric Company, 136 Liberty street, New York, are two of the largest ever awarded for the equipment of interior telephones. One of these is for the telephonic equipment of the St. Paul building at the corner of Broadway and Ann street, New York, with 359 telephones and the other the Bowling Green Building with 300 instruments. Both these installations will be provided with a telephone in each office connected with a switchboard at the elevator landing on the ground floor. The tenants in each of these buildings will therefore be able to communicate with one another and communication can be had with each office from the switchboard on the ground floor. The instruments will be of the well-known Ericsson Swedish type recently described in The Electrical Engineer.

Among the other buildings recently equipped by the Wilson-Bates Electric Company are the Roosevelt Hospital and the Bloomingdale Insane Asylum.

INTERIOR CONDUIT IN THE WEST.

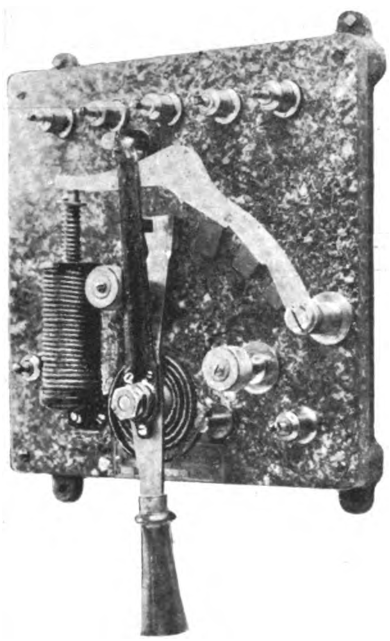
A great deal of interest has been felt in regard to interior conduit in the West, and we are now able to report that the Central Electric Company, so long identified with this popular auxiliary of the wiring business will continue to handle it in the territory where they have sold it so long. At the same time, as noted by us recently, an agency has also been granted to the Western office of the Western Electric Company, for business in that section of the country. The demand for interior conduit appears to be nothing short of illimitable, and the Interior Conduit and Insulation Company have lately been largely increasing their facilities for its production. Through factory changes incident to the introduction of new machinery for this branch of manufacture, the company have moved their

offices to the second floor, leaving the first floor entirely for brass armored conduit alone.

THE STRANGLAND SWITCH.

WHILE the convenience of rheostats is undisputed, their use almost invariably entails a loss of current which is wasted in heating them. To avoid this waste in cases where direct connected series wound motors are used, as with ventilating wheels or fan motors, and generally for work where variations of speed are required, the C. & C. Electric Company, of New York, build the Strangland switch, illustrated in the accompanying engraving.

This switch controls the motor without the use of resistances, its function being to effect the commutation of the field coils. The switch is also designed to automatically cut out the motor for current interruption at any speed.



THE STRANGLAND MOTOR SWITCH FOR SERIES MOTORS.

HUGO REISINGER'S "ELECTRA" CARBONS.

Hugo Reisinger, of 58 Beaver street, New York, reports of an extraordinary increase in the business for the "Electra" high-grade Nuernberg carbons. He recently received the following letter from a leading electric lighting station: "Please enter the enclosed order for carbons, to be of the celebrated "Electra" brand. The shipment furnished us was so far superior to anything heretofore used by us, that we have concluded to adopt the "Electra" carbons exclusively for our arc lighting in the future." The above letter is one of the many testimonials which Mr. Reisinger has received, and certainly speaks very highly for the merits of the "Electra" carbons with which he supplies the trade.

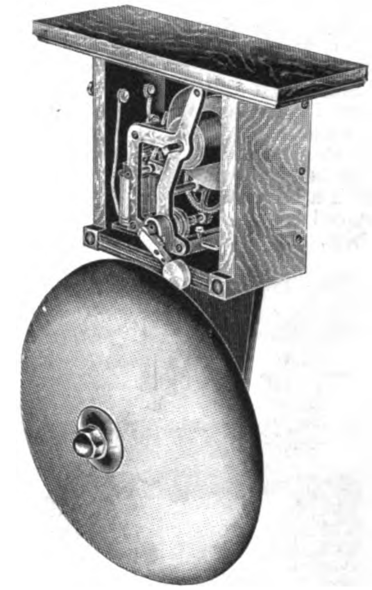
WARREN ELECTRIC CO.

The Warren Electric Co., of Chicago, have consummated quite an important electrical deal in Ohio. They have organized a corporation entitled the Warren Electric Manufacturing Company with principal offices at Sandusky, O. The Warren Electric Manufacturing Company has purchased the large manufacturing plant known as the Barney and Kilhey works, which are complete in every respect, and have a fine equipment of machinery and tools. The buildings which are large and substantial, are built of stone, are most centrally located in the city of Sandusky. The capital of the new concern is $200,000, fully paid up, and the business of the company will be managed by the president, Mr. C. C. Warren, who will make Sandusky his home.

HENRY R. WORTHINGTON COMPANY, manufacturer of pumping machinery, has just received word through its London office that the exhibit of Worthington pumps at the Hungarian National Exhibition at Budapest has been awarded a grand millennium medal. This medal is the only award made for pumping machinery at the exhibition.

EDWARDS & CO'S. NEW ELECTRO-MECHANICAL GONG.

THE new electro mechanical gong manufactured by Edwards & Co., 144th street and Fourth avenue, New York City, is a decided departure from those types now on the market. As will be seen in the accompanying engraving, the hammer is pivoted at the post. When released it makes a full revolution, passing under the gong, and is raised by an inclined plane, strikes the gong a powerful, clear blow and drops to its normal position under the gong. After the first blow the armature remains close to the magnets, so that very little power is required to operate it and very rapid blows may be struck.



THE EDWARDS ELECTRO-MECHANICAL GONG.

The smaller sizes, 4 inches to 8 inches, are encased in a polished wood box with a nickel-plated front, to which is attached the entire mechanism of the bell. By unscrewing this front the whole bell may be removed from the case and the inner parts exposed. Lantern pinions and a very strong spring encased in "main spring box" are used.

The larger sizes, 10 inches to 30 inches, are mounted on a cast frame and entirely encased in a polished wooden box, the front of which can be removed, as shown. The wheels are cast bronze and the pinions of solid steel. This style is made to operate by either a spring or weight, and will strike about 500 blows to each winding.

These bells can be arranged to continue striking single rapid blows until the circuit is broken. Being dust and damp proof they may be used in exposed places.

GORDON-BURNHAM PRIMARY BATTERIES IN FIRE AND POLICE TELEGRAPH WORK.

The Gordon cells which were installed in the Brooklyn Fire Department on March 19, 1896, are still operating successfully. There were thirty cells of the No. 1 type which replaced 40 gravity cells on circuit No. 3. The current discharge at the day of installation was 85-1000 ampere normally at an e. m. f. of 20 volts. At the present time, after being on closed circuit for over eight months, they are showing a current output of 75-1000 ampere, at an e. m. f. of 19 volts. These measurements were taken on Weston instruments by Mr. W. C. Banks, electrician of the Gordon-Burnham Battery Company. This company guarantee their cells on closed circuit work at a current output of 8-100 of an ampere, as required for fire alarm work for six months. This ought to demonstrate to the users of primary battery current of what stuff the Gordon cells are made. They have also been in the Police Department of Brooklyn city; there were installed on Jan. 22, 1896, two circuits with Gordon cells for police telegraph service, which are still going. The maximum current discharge on this work is 25-1000 of an ampere, at an e. m. f. of 11 volts. Mr. Mason, superintendent of the Police Telegraph, and Mr. Walter, Acting Superintendent of the fire alarm telegraph system of the city of Brooklyn, are highly pleased with the successful working of the cells on their circuits.

STAMFORD, CONN.—Among the numerous contracts which the Berlin Iron Bridge Company have secured of late for steel

roofs covered with corrugated iron lined with their patent anti-condensation roof lining, is the roof for the new power station for the Stamford (Conn.) Gas and Electric Company. The layout of this station is very convenient, and the construction is to be the very best. The engine and dynamo room is 60 feet wide and 100 feet long, and the boiler room adjoining is 40 feet wide and 75 feet long. The walls are of brick, and the framework of the roof as well as the supports for the traveling crane in the engine and dynamo room are of steel. The Berlin Company have the contract for furnishing and erecting all of the structural steel work.

ADVERTISERS' HINTS.

CENTRAL ELECTRIC COMPANY carry in stock a variety of special wires for office, switchboard and metallic circuit service for telephone exchanges. Okonite insulation is always used and the wires will be found equal to the severest requirements of the most advanced telephone practice.

THE ALBANY STEAM TRAP COMPANY furnished the steam traps for the Paterson Edison Company's station.

THE C. & C. ELECTRIC COMPANY advertise motors for direct connection to ventilating fans and for direct coupling to blowers, blasts, etc. They also mention their type 4 P. motor for power work.

MITCHELL TEMPERED COPPER COMPANY, Corry, Pa., are supplying copper for all purposes where the tempered metal may be used. Commutator segments and bevel bars are their specialty and customers may be sure of high-grade quality in goods sold under their trade mark "M."

THE GENERAL ELECTRIC COMPANY point out some of the advantages in central station equipment comprising direct current apparatus for distribution over net work of mains, and multiphase apparatus for transmission feeders and tie lines, by transformers and rotary converters.

HASCALL STEAM GENERATOR COMPANY have something to say regarding their system which they install under the condition of forfeiting payment in the event of its not fulfilling their claims for it.

THE McCLELLAND OIL PURIFIER CO., 66 Broadway, New York, have a method of cleaning oil which employs water and heat. Their purifier combines an ornamental storage reservoir as well.

THE NEW YORK AND NEW JERSEY LUBRICANT CO., 30 Cortlandt street, New York, advertise Kent's lubricating compound requiring 350 deg. of heat to melt it. They refer to several large plants where it is in use, among them being the Edison Electric Illuminating Company, of Paterson, N. J.

THE KENSINGTON ENGINE WORKS, Ltd., Philadelphia, advocate the Beckman system of forced draft as a money-saver both in repairs and in the cheaper grade of fuel which may be utilized.

GOLDMARK & WALLACE, 29 Chambers street, New York, are the United States agents for the Koch woven wire dynamo brush. These brushes have met with universal favor in Germany and bid fair to in this country, as well, owing to the many points of excellence which they embody.

E. H. KELLOGG & CO., New York, have dealt largely in lubricating oils since 1858 and their long experience enables them to suit all their customers in supplying the best grades for dynamos, engines, railways, ice machines, steamships, etc.

MR. E. YEOMANS, 60 Canal street, Chicago, is the Western agent for Zimdars & Hunt and is well prepared to fill orders from Chicago stock for automatic switches for electric motors or any of the other specialties carried by this well-known house.

THE BERLIN IRON BRIDGE COMPANY, East Berlin, Conn., illustrate in their "ad." this issue, an iron truss roof with a traveling crane both of which were designed and built by them for the Narragansett Electric Lighting Company, of Providence, R. I. The side walls are of brick, making a fireproof structure which should commend itself for central stations or other uses where the fire risk is ordinarily great.

THE EVANS MARBLE COMPANY, of Baltimore, devote special care to the supply of marble for switchboard slots and interior work. One of their recent shipments was for the switchboards in the station of the Edison Company, of Paterson, N. J. The marble was quarried to bring out the veins and the boards present a very handsome appearance.

THE KEUFFEL & ESSER COMPANY, 127 Fulton street, New York, say they have the largest and best stock of drawing materials and surveying instruments in America. Engineers and those interested will do well to drop them a card and receive their catalogue.

THE ELWELL-PARKER ELECTRIC COMPANY, of America, build a complete line of modern direct connected slow-speed and belt-driven moderate speed dynamos for power, lighting and electro deposition work. They also make standard motors for driving shop power tools, pumps, hoists, cranes, etc. Their catalogue is ready for distribution.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., advertise generators and motors of superior design and liberal proportions, low temperature and high efficiency.

THE KENT ELECTRIC MANUFACTURING COMPANY, 47 Hermon street, Worcester, Mass., are placing on the market sewing machine motors for which they claim absolutely perfect speed regulation. They are made for family and factory use.

THE GILMORE ELECTRICAL AND MANUFACTURING COMPANY, North Easton, Mass., give five reasons why the "96" cut-out is the best. They claim special advantages for their fuse blocks, of which they carry a complete line, and on which they will be glad to quote prices.

THE ELECTRIC STORAGE BATTERY COMPANY point out the advantages of a battery of chloride accumulators in an office building. It acts as a regulator of potential permitting the lamp and elevator services to be taken from one generator, which is run at normal steady load and it furnishes the night service at a minimum cost.

THE BALL & WOOD COMPANY, 15 Cortlandt street, New York, have installed for the Edison Electric Illuminating Company, of Paterson, N. J., six 600 horse-power and one 450 horse-power engines of the fine type shown in their "ad." They are now building for the same company two 750 horse-power vertical engines of the same general type but designed for rope transmission.

THE WESTERN TELEPHONE CONSTRUCTION COMPANY, Chicago, publish a partial list of exchanges using their apparatus, representing over 22,000 instruments.

McLEOD, WARD & CO., 27 Thames street, New York, direct attention to the Kinsman desk lamp which has proved itself of great value in offices where the light is poor.

THE GENERAL INCANDESCENT ARC LIGHT CO., New York, illustrate the special quick break switches designed for the Edison Company, of Paterson, N. J., and also the new Bergmann enclosed arc lamp which they claim to be the best and cheapest 150-hour arc lamp on the market.

THE IDEAL ELECTRIC CORPORATION, New York City, are well prepared to furnish switches and switchboards of any size and for every class of work.

ROSSITER, MACGOVERN & CO., New York, present a very excellent list of bargains in dynamos and transformers.

M. E. SANGER & CO., 36 Cortlandt street, New York, remind their friends that they are thoroughly equipped for the manufacture of intricate and special devices. The feeder indicators in the Paterson Edison Company's station were constructed by this firm.

JOHN W. FERGUSON, 253 Broadway, New York, was the contractor for the station of the Edison Electric Illuminating Company, of Paterson, N. J.

WM. TAYLOR, 203 Broadway, New York, draws notice to his enclosed 150-hour arc lamp which he will send on trial to possible purchasers. "Take him up."

THE IRON CLAD RHEOSTAT COMPANY, Westfield, N. J., have a large variety of rheostats for all general uses and make a specialty of theatre work.

THE BRODIE ELECTRIC COMPANY, Manchester, N. H., recommend the "Brodie" single-pole combined switch and fuse box for high tension currents. It is intended as a primary cut-out for use with transformers and in general outside construction work.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., present a cut of an American-Ball engine which has received the best work of Mr. F. H. Ball, whose efforts in engine building have always been crowned with success. Some of the new features are larger crank shafts, automatic circulation of oil and a governor which embodies fine regulation.

HERRICK & BURKE, 150 Nassau street, New York, were the engineers who planned the station of the Edison Electric Illuminating Company, of Paterson, N. J., described in this issue.

THE EATON, COLE & BURNHAM COMPANY, New York, are the manufacturers of the "Eaton" iron body, bronze mounted, gate valves for high pressures.. These valves are fitted with double, parallel faces and are adapted for electrical and other steam plants where high pressures are used. They also furnish fittings of all sizes and steam metal valves, and cocks for ordinary and heavy pressures.

CUTLER-HAMMER ELECTRICAL GOODS.—In calling attention to the special announcement of the Cutler-Hammer Manufacturing Company, of Chicago, in this issue, it may be noted that the company have been enjoying a fine rush of business since the election and have booked orders during the month of November that amount to more than double that in any previous month. Mr. E. W. Hammer informs us that they find the demand for their starting rheostats specially ac-

tive, due in part to the very low prices they have made on their smaller sizes. They have been compelled to increase their force largely and are now working overtime to keep up with orders. The company invite correspondence as to any of their specialties.

K. McLENNAN & CO., of 206 Dearborn street, Chicago, sole manufactures of the celebrated Gale's Commutator Compound, stated to a representative of The Electrical Engineer, that they would keep open their invitation, extended through the columns of this paper, to all users of generators and motors, who are troubled with sparking and cutting of commutators, to send to them a free sample stick, for some time to come. Through the columns of this paper, they will report the results of trials, and all who have not tried this compound should write to them for a sample and convince themselves of its merits.

THE C. W. HUNT COMPANY, New York, are glad to answer any inquiries concerning coal handling problems and will send their catalogue, "Coal Handling for Steam Generators," to any one interested in these matters.

HENRY W. BULKLEY, 39 Park Row, New York, advertises the Bulkley "Injector" condenser and points out several of its commendable features.

MINER & CO., 1366 Broadway, New York, make a specialty of electric signs for the trade, keeping in stock 18-inch, 24-inch and 36-inch block letters. They also make to order script and other unique designs.

HINE & ROBERTSON, present a very "pat" cut, "Help the Blind," in their advertisement, and suggest how many electric light and power plants are simply guessing that their engines are doing well, whereas if they owned an indicator, cards could be taken every day giving to the engineer very valuable knowledge and to the manufacturers of the plant an absolute knownedge that full power is being developed for the amount of coal consumed. The cost of an indicator is now within the reach of every one, and the day not far distant when every power owner will have one.

THE STIRLING COMPANY, Chicago, state that they have installed over 350,000 horse-power of their water tube boiler, claiming it to be the ideal boiler for central stations and street railway work.

THE WHEELER CONDENSER AND ENGINEERING CO., New York, call attention to the Barnard water cooling tower designed for steam plants where a natural supply of water for condensing purposes is not obtainable. They guarantee its efficiency and durability, while the cost of operation is small. They have removed to the Beard Bldg., 120-122 Liberty street, New York.

THE "OTTO CYCLE GAS ENGINE," by Wm. Norris, a book described in an accompanying advertisement, will be sure to assist its readers who are interested in gas engines from any point of view.

NEW ENGLAND NOTES.

WHEELER-REFLECTOR COMPANY, 18 to 24 Washington street, Boston, have just issued a new catalogue, in which prices have been reduced on over forty styles of their reflectors, shades, etc. The discounts remain as before, thus ensuring a reduced net cost. They will be glad to send the catalogue to any address on application.

THE HOWARD & BULLOUGH AMERICAN MACHINE COMPANY, Pawtucket, R. I., have let the contract for a new building, 324 feet long by 69 feet wide. This addition will be a three-story brick building and will give over 67,000 square feet additional floor space. This three-story addition will be driven and illuminated throughout by electricity.

THE HENDEY MACHINE COMPANY, Torrington, Conn., propose to drive their new shop building by electricity. They have installed their new 100 horse-power boiler and will put in a new large engine and Eddy dynamo.

NEW YORK NOTES.

THE WARD ELECTRIC SUPPLY AND CONSTRUCTION COMPANY has been formed with a capital stock of $15,000, and is due to a consolidation of the business of Deronda Levy & Co., and O. B. Greene. The offices are at 39-41 Cortlandt street and the store rooms at 14 Cortlandt. Mr. Greene will have charge of the office management and Mr. Levy will attend to the outside construction work.

THE WESTERN ELECTRIC COMPANY was given the contract on Dec. 4, for the incandescent electric lamps and wiring of the new part of the Hotel Waldorf. It is probably the largest contract ever given in United States, or the world, for installing an isolated plant.

ZIMDARS & HUNT have been awarded the contract for wiring the Van Ingen Building, 5-7 West Twenty-ninth street, city. They report orders for automatic switches as coming in very satisfactorily indeed. Large quantities have been sold these last two weeks.

The employés of Zimdars & Hunt, 127 Fifth avenue, city, held their third annual ball Dec. 1, at Lyric Hall, Sixth avenue and Forty-second street. The hall was profusely decorated with about 500 lamps in addition to the many flags and bunting. Over the stage was a fine design of the monogram of Zimdars & Hunt, surrounded by the name of the associated employés. Above this was a large sign 30 feet long, lit up with 227 incandescent lamps forming the word "Welcome." The affair was a most enjoyable one to the 200 couples participating in the dancing which lasted until the small hours of the morning. Speeches were made by Mr. Hunt, and by the president of the Z. & H. Association, Mr. G. T. Butler, who worked indefatigably for the success of this and the previous balls.

THE MECCA of late for all the maimed and injured in New Jersey has been the Edison Decorative and Miniature Lamp Department (General Electric Company), Harrison, N. J. Although not encouraging, the visits of these unfortunates, quite a number of sufferers have journeyed to the works to have bullets and other foreign matter located in their system, it being generally known that the department, Harrison, N. J., manufacture some of the best X-ray apparatus on the market. This concern manufactures also electric signs and a large line of miniature and decorative lamps. Catalogues will be cheerfully mailed on application.

HAMMACHER, SCHLEMMER & CO., 209 Bowery, New York, carry a large and varied line of steel wire, suitable for springs for switches, etc. They sell also a well made and substantial lock for telephone boxes. The firm of Hammacher, Schlemmer & Co. solicit correspondence regarding their specialties.

JOHN SIMMONS COMPANY, 106-110 Center street, New York, manufacture the Excelsior railway bracket. This bracket is probably one of the most simple, practical and durable of makes now on the market. The Hercules switchboard is another one of their excellent electrical specialties. This firm will be pleased to mail circulars and prices to any address on application.

UEHLING, STEINBART & CO., Ltd., 63 Mulberry street, Newark, N. J., manufacture a highly sensitive, accurate and durable pneumatic pyrometer. It measures and records temperatures to 3,000 degrees. The demand for this pyrometer, a most ingenious invention, is steadily growing and it is fast replacing other makes in the different industries of this country. Messrs. Uehling, Steinbart & Co. report having recently placed a number of their pyrometers in several of the largest smelting furnaces in Pensylvania.

CHAS. J. BOGUE, 206 Centre street, New York City, manufactures arc lamp supplies, American system, carbon holders for all types of arc lamps, etc., and will be pleased to submit prices, etc., on application.

STUCKY & HECK ELECTRICAL MANUFACTURING COMPANY, Ltd., 35 New Jersey Railroad avenue, Newark, N. J., report running busy with a full complement of men in all branches of their work. They repair, rewind or reconstruct any make or system of armatures, lighting dynamos, power generators, motors and transformers, etc. The heads of this firm are both thoroughly practical men, which accounts for the excellent work turned out from their factory.

HAMMERSCHLAG & CO., 26 Liberty street, New York, note a marked improvement in their business, and orders are much on the increase. They manufacture X-ray outfits, small sizes of motor transformers for charging batteries, dynamo brushes of highest grade and a large variety of electrical specialties.

J. ERLANDSEN, 172 Centre street, city, has been identified for many years with the machinery trade. His specialty is the manufacture of milling cutters, aside from which he makes light machinery and tools, also special machinery and model and experimental work.

THE HINE & ROBERTSON CO., 98 Cortlandt street, New York City, have received a letter from the chief engineer of the Thorndike, of Boston, in which he says that he packed some boxes in July, 1895, with "Eureka" packing. The pump on which this packing was used has run continuously day and and night ever since, which is the equivalent of a three years' ordinary run, ten hours to the day, and the boxes are absolutely tight at the present time. This is a remarkable experience, and speaks volumes for this packing. The Hine & Robertson Co. will be glad to forward samples to any engineers communicating with them.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

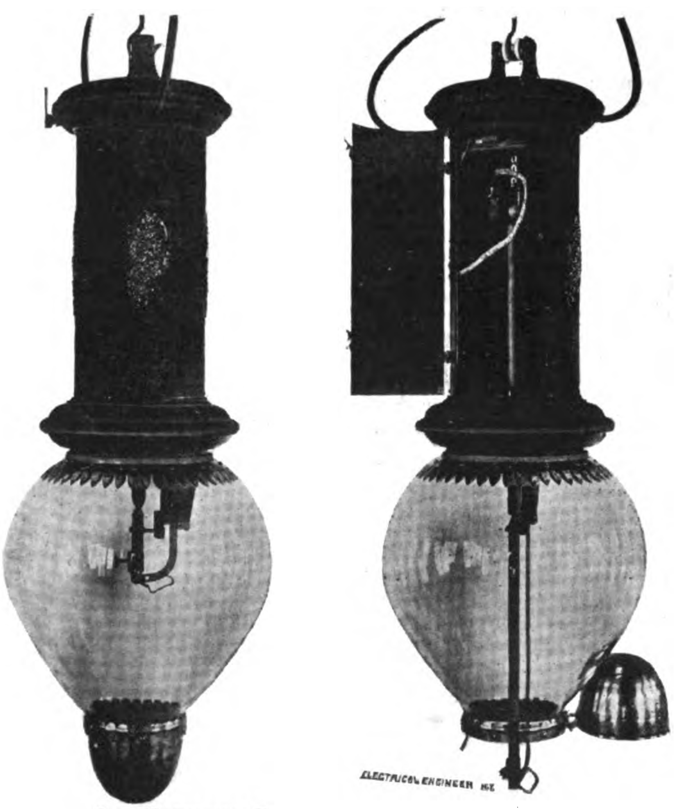
Vol. XXII. DECEMBER 16, 1896. No. 450.

ELECTRIC LIGHTING.

THE NEW ARC LAMPS OF THE EXCELSIOR ELECTRIC CO.

SINCE arc dynamos of 150 and even 200 lights of 2,000 nominal candle power, have been successfully built, the lamp problem has assumed additional importance. The ordinary lamp takes from 3 to 5 volts to feed. When cold it draws an arc at 45 volts; but, after the shunt spools warm up, the voltage rises to 55 and even 60 volts. If the dynamo is a 150-light machine, at first it will have to generate 6,750 volts, but when the lamps get hot, it will have to generate 8,250 volts, assuming 55 volts per lamp. In addition to the inherent disadvantage due to the increased voltage, this represents an increase of 20 per cent. in the power required for the lamps.

These facts show the desirability of a lamp of approximately constant voltage. In the new lamp of the Excelsior Electric Company, shown in the accompanying engravings, this result has been accomplished, as it feeds on a variation of 1 volt, and the feeding point does not rise as the lamp gets hot.



THE EXCELSIOR ELECTRIC CO.'S NEW ARC LAMPS.

A detailed description of the distinctive features by which this result is accomplished will be found of interest.

It has been the aim, in constructing this lamp, to facilitate trimming and globe cleaning to the utmost extent possible. The lamp burns but one set of carbons in fifteen hours' service, the upper carbon being ⅝ inch diameter by 14 inches, the lower ½ inch in diameter by 12 inches long. The light remains practically in the same spot, 27 inches below the top of the lamp, the length of the lamp being 32 inches from the suspension hook to the bottom of the ash pan.

The upper carbon is clamped in a block of metal suspended from a chain which rests on a sprocket wheel and carries the lower carbon rod on its other end. The shaft of the sprocket wheel revolves in bearings formed on the end of a V-shaped casting which turns on trunnions, screwed into upright posts, extending upwards from a plate which carries the lamp mechanism.

A magnet spool in series with the carbons, strikes the arc by tilting the frame upwards when current is supplied to the lamp. The sprocket wheel shaft also carries a worm wheel which can engage the former, if pushed towards it, as the faces of both wheels are provided with teeth which will interlock. The shaft, with sprocket wheel attached, is pushed towards the worm wheel by a flat spring when current energizes the series coil, and tilts the frame upwards; but is forced back again by a lever, when the current is withdrawn and the frame has dropped downwards. In the latter position of the frame the sprocket wheel can turn freely with its shaft and will allow the carbons to come in contact.

The worm which engages the wheel is under the control of a pair of shunt spools, fitted with a self-interrupter of the current. As the arc grows longer, the spools will receive more current and the iron armature will be attracted to such an extent that it will finally open the shunt circuit. The retractile spring immediately pulls the armature back and closes the circuit again. This oscillatory motion is utilized to turn the worm step by step and causes the carbons to approach each other until the tension has been reduced sufficiently to bring the armature of the shunt magnet to rest.

As the globe of the lamp is completely closed by coming up to the lamp casing, the heat from the arc is imparted to the lamp mechanism and the shunt-magnet coils. If the latter are composed of copper wire they will have their resistance increased considerably by the heat and the passage of current thereby diminished. As the length of the arc is controlled by the shunt-magnet, it follows that it will increase as long as the heat does. To obviate this objectionable feature the shunt spools are composed of German silver, whose resistance increases but twenty one-thousandths of one per cent. for each degree Fahrenheit, while copper wire increases twenty-one-hundredths per cent.

These lamps answer for constant potential as well as constant current with but little alteration. If used for constant current they are provided with automatic cut-outs, to preserve the continuity of the circuit and also with short-circuiting switches. The lamps for constant potential have the switches arranged for opening the circuit. They do not need the automatic cut-out, but carry a German silver rheostat in an iron casting on the top of the lamp.

Opening the door of the lamp case to re-carbon the lamp does not expose the lamp mechanism to the inclemencies of the weather, but gives admission to a chamber merely in which the upper carbon holder slides up or down.

In order to place the lower carbon into its socket it is not necessary to remove the globe as the opening of the ash pan gives easy access to the hand of the trimmer for globe cleaning and re-carboning.

The globe is suspended from the lamp casing by a ring which carries three lugs engaging with three projections on the bottom of the casing. The terminal clamps for holding the ends of the line carrier or cables can be opened or closed from the outside. The lamp case does not need to be opened at all, for these operations.

INCREASE OF NEW YORK ARC LIGHTING.

At a meeting of the New York City Gas Commission recently it was decided to put in 575 additional electric lights in the city. Ninety-two of these will be above the Harlem River in the vicinity of Van Cortlandt avenue. The cost of the city's public lighting this year is $1,087,813, an increase over last year of $43,000.

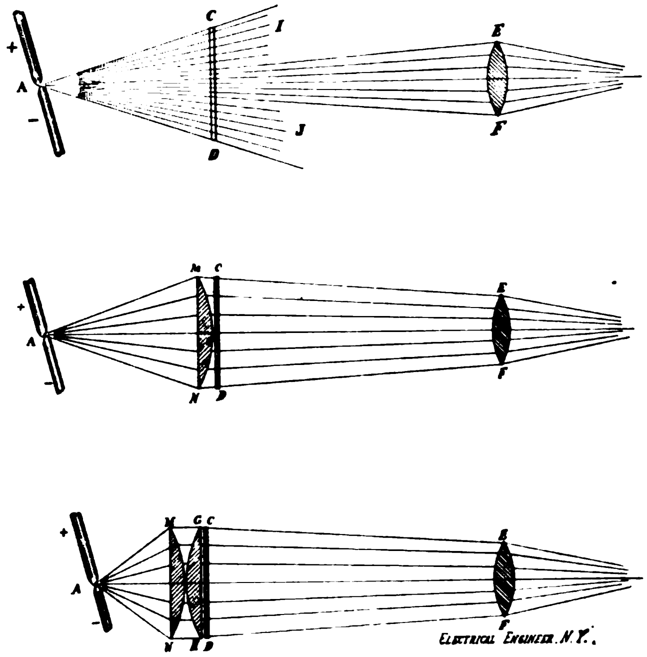
THE ELECTRIC ARC FOR LANTERN PROJECTION.—I.

BY E. P. HOPKINS.

THE projection of a concentrated light upon a surface for illustrating and other purposes, has, within the last few years, become so important that it has turned many minds towards the subject, with the usual successful results.

The first consideration is the form of an illuminant, or light, the following list being now in use: 1. Oil lamps. 2. Illuminating gas. 3. Illuminating gas used with the Welsbach burner. 4. Acetylene gas. 5. Oxy-hydrogen gas, in combination with lime or calcium. 6. The electric incandescent. 7. The electric arc.

As the electric arc so far surpasses all the other forms of light, our chief attention in this article will be given to it. I will briefly run over the main difficulties with the other forms of illumination. We will first take the oil lamp. This light is difficult to use with projection work on account of the illuminant covering a large surface. This is unavoidable if we wish to obtain a bright light, as we are bound to use one or more wicks. There is a great deficiency of white rays in the oil light, which has a very yellow or orange tinge. With the house gas, or common illuminating gas, it is difficult to make it sufficiently concentrated to give as good a light as that of the oil, but when used with the Welsbach burner, which practically is a form of incandescent light, it possesses the hue peculiar to it. This is almost twice as strong as regards white light, as most oil lamps, and when tested side by side, under exactly the same conditions, gives about twice the illumination of that produced by the best oil lamp.



FIGS. 1, 2 AND 3.

We next come to acetylene gas, which is very much superior to either of the preceding illuminants. It is extremely white, and by using three or four flames, one behind the other, we get a solid light which seems to greatly increase its brilliancy when used as a projecting illuminant. When compared with the Welsbach or the oil light, it is about four or five to one in favor of the acetylene.

Next to this gas comes the oxy-hydrogen, or lime light. This, when burning at its best, will produce from 500 to 800 candle-power, and in comparison to the acetylene gas is about seven to five.

We next come to the incandescent electric light. This, after considerable experiment, has been put into such a shape that it makes a very satisfactory illuminant for the lantern. It is necessary to have the filament of the lamp coiled up into a small spiral, not more than half an inch in diameter. In this manner we get the incandescent part concentrated into one spot, and in that way obtain the best results, as will be described later.

We next come to the arc light, which we will describe more in detail, as it is the most perfect and ideal illuminant for optical projection work.

The principle of all projections is to illuminate the object which is to be projected, as brilliantly as possible. The light radiating, transmitted or reflected from the object, is concentrated by an objective lens upon the surface where the projection is to be made. In projecting any object that itself gives out light, such, for instance, as a candle, all that is necessary is an objective lens which will concentrate the rays of light upon the screen; but when the object is transparent or opaque, the problem is different, for the subject must be illuminated so brilliantly that the rays of light passing from it to the objective must be bright enough to be distinctly seen upon the screen.

In Fig. 1 the object C D is transparent as an ordinary lantern slide through which the rays of light from the illuminant A pass to the objective E F, and so focused upon the projecting surface or screen. It will be seen that only a few rays of light passing through the center of the slide strike the lens, the others, I J, pass outside the lens, therefore the picture projected upon the screen will only be the center part of the slide C D through which the above rays of light pass.

In order to produce an equal illumination over the entire slide C D, it is necessary to have a condensing lens, shown in Fig. 2, where A is the illuminant; E F, the objective; C D, the slide; and M N is the condenser lens. This lens concentrates or refracts all the rays of light that strike it and after passing through the slide C D, they all pass through the objective lens E F, so that all parts of the slide C D are equally illuminated.

It will be noticed that if the light A is brought nearer to condenser M N, more rays or a wider angle of light will strike the lens and thus more light will be refracted through the slide C M, to the objective E F.

To produce this effect the condenser would have to be extremely short in focus; therefore, in practice it is found more convenient to use two lenses, M N and C H, which, together, produce a very short focus. When these roomssycg produce a very short focus. When these lenses are placed together the combined focus will be 3 inches.

This distance of 3 inches has been found to be a perfectly safe distance for the electric arc, when using from 7 to 18 amperes, that is, if the lenses are mounted loosely so that they can expand as they become heated. In order to allow for this expansion these condenser cells are constructed as in Figs. 4 and 5. The former is an end view of the condensers and cell that is next the light, and Fig 5 shows a section at right angles to the plane of the lenses, thus showing the springs that support the smaller lens.

In order to get the most perfect concentration of light from these lenses, it will be necessary to have the illuminant as small as possible, that is to say, to be as nearly as possible a point of light. In the oxy-hydrogen or calcium light, the illumination is spread over fully three-quarters of an inch of the lime cylinder, its entire width being half an inch; while with the electric light, when giving fully twice or three times as much illumination as that of the lime light, the surface is not more than three-sixteenths of an inch in diameter. This is at the extreme point or crater of the positive carbon giving 80 per cent. of the entire light. In order to obtain this light, and to avoid the spot of light from the negative carbon, the lamp is tilted so that the point of the positive carbon points towards the condensers. By this concentration of light, a very minute focus is obtained, so that we can bring the concentrated rays of light from the condenser to pass through an aperture not more than one-eighth of an inch in diameter. This is very necessary for all microscopical projections where one has to illuminate a large field or screen with an aperture in the lens of not more than one-sixteenth inch. The best results with the microscope are obtained by using extra condensing

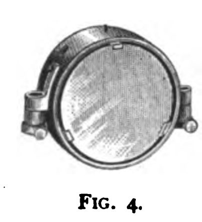


FIG. 4.

FIG. 5.

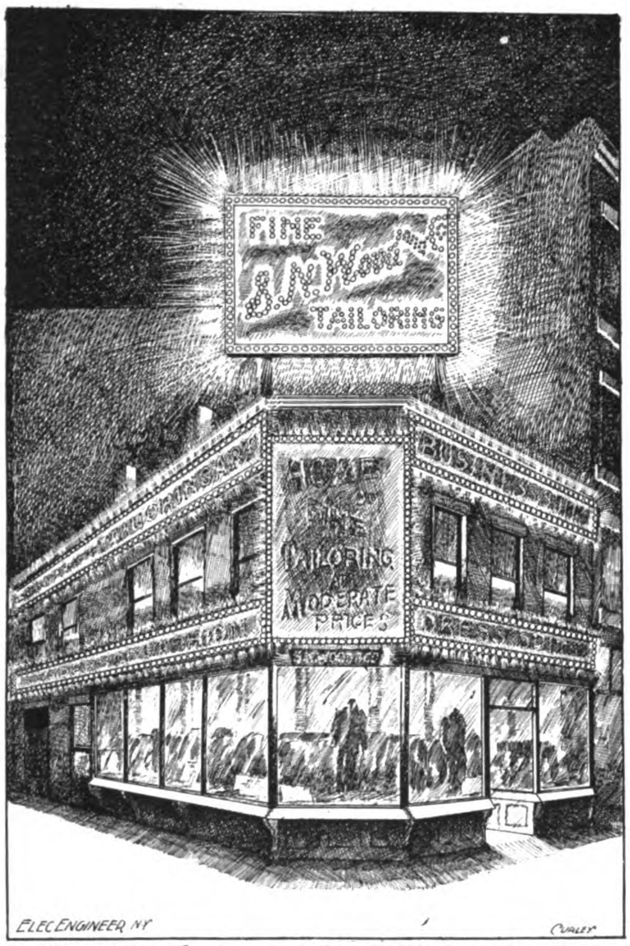
lenses, so that very little of the light is lost. With the lime-light, and all other illuminants, we cannot concentrate the light to a very small point on account of its emanating from such a large surface. It is also found, on account of the electric light emanating from such a small point, that the rays of light passing from the lenses or reflectors can be refracted or reflected so perfectly that they will extend to any distance, making the only perfect form of searchlight.

Another point of greater consideration in lantern projection is that the electric arc light, although so intensely brilliant, does not radiate much heat. Thus the illuminating power of the electric lantern is almost unlimited. Using the

electric lamp with from 18 to 20 amperes, the same condensers may be used as those for the oxy-hydrogen, that is to say, a may be used as those for the oxy-hydrogen. Great care must, of course, be taken in supporting the lens, as described above.

STORE LIGHTING EFFECTS IN NEW YORK CITY.

SEVERAL notable electric lighting effects may be found in and upon New York stores, and some of them have been illustrated in the pages of The Electrical Engineer. It may be doubted, however, whether more light has anywhere been crowded into a given store space than can be seen nightly at the establishment of S. N. Wood & Co., on upper Broadway. It is certainly the most brilliant spot in the dazzling "Tenderloin," and it would be difficult to squeeze in more lamps to the square foot of store front. The sketch herewith gives a faithful view of the store at night. The building is only two story, and hence the lighting effect is highly concentrated.



A SPECIMEN OF ILLUMINATED STORE AND SIGN, NEW YORK.

There are 300 Edison lamps of 8 candle power in the roof sign. In the large panel in the center of the front, the frames around the signs under the eaves and over the windows are 400 lamps of 8 candle power. The smaller sign below the center panel contains 96 Edison lamps of 3 candle-power, grouped in 12 series, there being thus 8 in each. Inside the building are no fewer than 300 lamps of 16 candle power and 2 arcs. It will be seen that no fewer than 1,100 lamps are employed for the illumination of this one store, the proprietors of which exhibit an enterprise upon which every electrical engineer looks with admiration. The sign work was done by Miner & Co., and the current is supplied from plant No. 1 of the Block Lighting and Power Co., corner of Thirty-first street and Broadway.

BENT CONDUIT TUBING.—On and after January 1, 1897, the Brotherhood of Electrical Workers will not connect up any bent conduit tubing except what is bent on the job. This rule will not, however, apply to what are known as standard elbows, which are regarded as coming under the ordinary run of work.

ELECTRIC TRANSPORTATION.

THE INSTITUTE DISCUSSION ON ELECTRIC TRACTION UNDER STEAM RAILWAY CONDITIONS.—III.

BY CHARLES H. DAVIS.

The subject of "Electric Traction Under Steam Railway Conditions" can be divided into a consideration of:

1. New Roads to be built.
2. Old Steam Roads to be partially or entirely changed over.

The relative merits of the use of "Electric Traction" or "Steam Locomotive Traction" in each of the above cases can be considered under the heads:

First Cost.

Total Expenses: (1) Fixed charges. (2) Maintenance. (3) Operating expenses.

Gross receipts.

1. NEW ROADS TO BE BUILT.

First Cost.—The cost of right of way, stations, terminals, fencing, grading, ballasting and track, will be approximately the same in either system. Overhead line work, or third rail and feeder system, including track, ground and feeder returns, are not required for steam traction and their cost is an additional charge against electric traction. The cost of equipment, excluding locomotive, is in favor of steam traction, as roughly it may be considered that the motors and controlling devices, or the electric locomotive are the items making up the increase in first cost of electric traction. In the first cost of power plants we can assume buildings to be nearly the same—several round houses as against fewer power houses. The steam and electrical plants, including foundations and stack, will not only exceed the cost of locomotives and tenders per horse-power, but in the use of central electric stations a greater amount of horse-power must be installed. This is especially so when lines are very long, making it necessary to duplicate the central station, or use sub-stations, or both, before it becomes necessary to duplicate locomotives by changing them. Should the headway of trains and their weight and capacity become similar to street railway practice in large cities, then, and only then, would electric power be less in first cost than steam locomotives; if the total power required were large, this might even result in lower first cost of the entire system.

No attempt has been made to give figures, as each individual case must be studied and the difference in first cost determined; but it will in general result in favor of locomotive traction with the exception noted.

Total Expenses.—(1) Fixed Charges: These will be greater for electric traction owing to greater first cost, except in the one case mentioned above.

(2) Maintenance: This subject is too wide to be fully discussed here; but it can be assumed that permanent way, track, car bodies, trucks and other items, the same in each case, would be maintained at equal cost. It is probable that the cost of maintaining the power plant, motors, line, etc., of electric traction would exceed the cost of maintaining locomotives, tenders, etc., and that the saving due to less wear and tear on track and rolling stock in electric traction would not make up for the difference. The liability to breakdowns in electrical apparatus is greater than in steam mechanisms, thus tending to increase cost of electric traction, not only on the line, but in the power house. Should the headway be decreased, as already suggested, the comparative cost of maintenance of electric traction would decrease, resulting in favor of such traction, although it may be hard to determine the line at which the saving over locomotive traction will take place.

(3) Operating Expenses: Administrative, legal and extraordinary expenses can be considered the same; train attendance the same, except in the case of close headway and the use of motors under each car, in which case electric traction shows a decided saving. Terminal, station, signal and telegraph expenses can be considered alike in each case. The cost of coal would depend largely upon the amount of power necessary to operate a given road; for the larger the power and more frequent the trains the greater the saving by the use of electric traction. Many central stations assumed to produce a horse-power at lower cost than by smaller units really do not, mainly due to the fact that so large a part of such a station is idle many hours of the day, and, although at their maximum point of economy, they are far ahead of small units, the question at issue is not "the cost of a horse-power at the station," but "the cost of a horse-power at the rim of the driving wheels."

The cost of this last mentioned horse-power for electric traction is not only made up of station expenses, but also line expenses and electrical equipment expenses, when compared to the cost of the same horse-power produced by a steam locomotive. When these facts are taken into consideraton, it is invariably found that the controlling factor is the headway of trains; the less the headway the more surely will it pay to use electric traction, and, vice versa, so far as the cost of a horse-power at the rim of the driving wheel is concerned.

A general conclusion would be that the question of total expenses depends so largely upon each individual case that only a study of it will enable one to arrive at a reliable result; but that with light weights, small capacity and frequent service, electric traction can be operated cheaper than locomotive traction.

Gross Receipts.—The question whether the gross receipts of a given road will be affected by the use of one or the other power under discussion is a most interesting one. Experience shows that where an electric road has paralleled a steam road it has taken most of the latter's business at first, but less as time went on; and that it created a demand for intercommunication which had never existed before—the bulk of the passenger travel coming from this cause. This is interestingly shown in the arguments of Judge Hall (vice-president N. Y., N. H. & H. R. R.) and Judge Gager, of Connecticut, before the Legislature of the State at its last session. This, of course, refers to passenger receipts only. Freight receipts would not be affected by the use of one power or the other, they increasing only as the country grows and rates fall, together with better facilities. Receipts from express and mails might be materially increased by the use of electrc traction when giving more frequent service. It appears that the close headway and "leave at your door" service of electric roads are the main reasons for their induced travel. The question of how much more the travel would be increased by the use of electric traction and frequent service is problematical, for the "leave at your door" service is wanting in steam railways as they are, but why not change them? If this could be done, past experience and data would give a good basis from which to estimate future results.

The conclusions one arrives at is that for long lines, infrequent service, where freight is a large proportion of the business, and where centers of population are far apart, the steam locomotive is the only paying method of to-day, as the first cost will be less, as well as total expenses. The writer has had several opportunities of determining these facts. What development may bring to electric traction in the far future cannot be foretold.

2. OLD STEAM ROADS TO BE PARTIALLY OR ENTIRELY CHANGED OVER.

First Cost.—What has been said under "new roads" will apply, with the additional disadvantage in the use of electric traction due to the increased first cost arising from the necessity of throwing away old steam equipment, either in part or whole. In some cases this would be unnecessary, as with large systems, where existing equipment could be used on that part where electricity did not replace steam locomotives.

Total Expenses.—Remarks under "new roads" will apply; and it would, therefore, appear that unless steam railways can change the character of their service to more nearly conform to street railway practice, they will be in many cases unable to adopt electric traction in place of steam locomotives to their own profit.

Gross Receipts.—What has been said under "new roads" again applies; therefore existing steam roads, to increase their gross receipts, must give quicker and more frequent service, and must give as near as possible the "leave at your door" service.

Conclusions.—The writer believes that electric traction will be profitable to steam railway systems when some or all of the following conditions are fulfilled, depending upon the special problem to be solved:

1. Steam railway managers must avoid making the mistake which took place in the change from horse traction to electric traction, namely, of trying to reduce the first cost of changing by the use of old methods, material and equipment, which, although entirely suited to the old system, proved most unsuitable under the new conditions. The tendency is to repeat this mistake, and too much stress cannot be laid upon avoiding it. The old equipment partly made over, the old method of operating, etc., will not bring success in the use of electric traction; and if followed from necessity, would indicate the strongest argument against the change.

2. Long distance, heavy trains and infrequent service if a necessity will prevent electric traction being profitable. Therefore, where gross receipts can be increased by light trains and frequent service, and thus decrease expenses, as compared to steam locomotives, electric traction will prove profitable. One of the best examples of how this could be applied is found in the suburban service of the Pennsylvania Railroad out of Philadelphia. It is, of course, understood that electric cars can be operated over the same tracks as trains drawn by steam locomotives. A change of system requiring more frequent service for success might necessitate one or more additional tracks, which, in some cases, would delay the time when a change would be advisable.

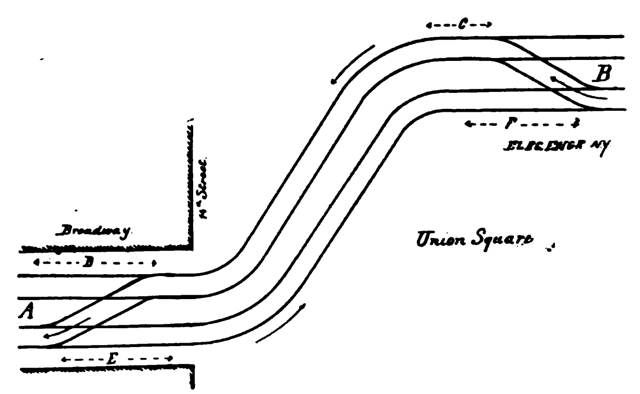
3. Steam railways, where the second condition is fulfilled, can better the results where they operate part of the system on the "leave at your door" plan. This suggestion may seem to some a radical departure, but I commend it to the careful thought of those interested.

A PROPOSED SOLUTION OF THE DEAD MAN'S CURVE PROBLEM IN NEW YORK.

BY B. J. H.

So much is being said and written about "Dead Man's Curve," at the corner of Fourteenth street and Broadway, New York, that I cannot help suggesting what appears to me a simple, practical and complete method of remedying the difficulty at comparatively small cost.

Referring to the accompanying diagram, there should be provided connecting switch tracks at A and B. One or two motors should run shuttlewise between A and B. They would go northward on the east track and southward on the west track, as indicated by the arrows. Thus they would push the northbound cars from E to F; then switch over and



DEAD MAN'S CURVE, BROADWAY AND 14TH STREET, NEW YORK.

push the southbound cars accumulated at C to D; at that point the motors would switch over again and repeat the operation continuously.

Enough ways of operating the shuttle motors at full power and controllable speed are easily available, such as the overhead, or conduit trolley, combined storage battery and underground strip, or, possibly, compressed air from a nearby supply. Even steam would be better than the present horrible work.

THE CINCINNATI HAMILTON AND DAYTON STEAM ROAD WILL ADOPT ELECTRICITY.

The Cincinnati,, Hamilton and Dayton Railroad has consummated a deal by which it becomes the owner of the street railroad lines in Middletown, Ohio. It will at once assume control, and as soon as possible the street car tracks will be connected with the tracks of the steam railway, and through cars will be operated from Middletown to Hamilton with electricity as the motive power.

The Cincinnati, Hamilton and Dayton Railroad will thus be the first to take up electricity as a motive power over its own rails. The equipment will be the most modern, and a very low schedule of fares will be adopted. This step on the part of the road is only the initiative, and will be followed by an extension of the system as rapidly as the circumstances will permit, and it will not be long before the service will be extended to Cincinnati. This will bring about a revolution in the road's suburban business, which is the heaviest of any line running out of Cincinnati. The electric service will, of course, mean more frequent cars.

THE STEEL MOTOR CO.'S NEW RAILWAY MOTORS AND CONTROLLERS.

AMONG the earliest to bring out a water and dust proof railway motor was the Steel Motor Company, of Johnstown, Pa. This company has steadily improved the design of its apparatus as suggested by continued use and is now bringing out its most recent types of 30, 40 and 60 horse-power steel motors.

The type C-3 motor, illustrated in Figs. 1 and 2, is rated at

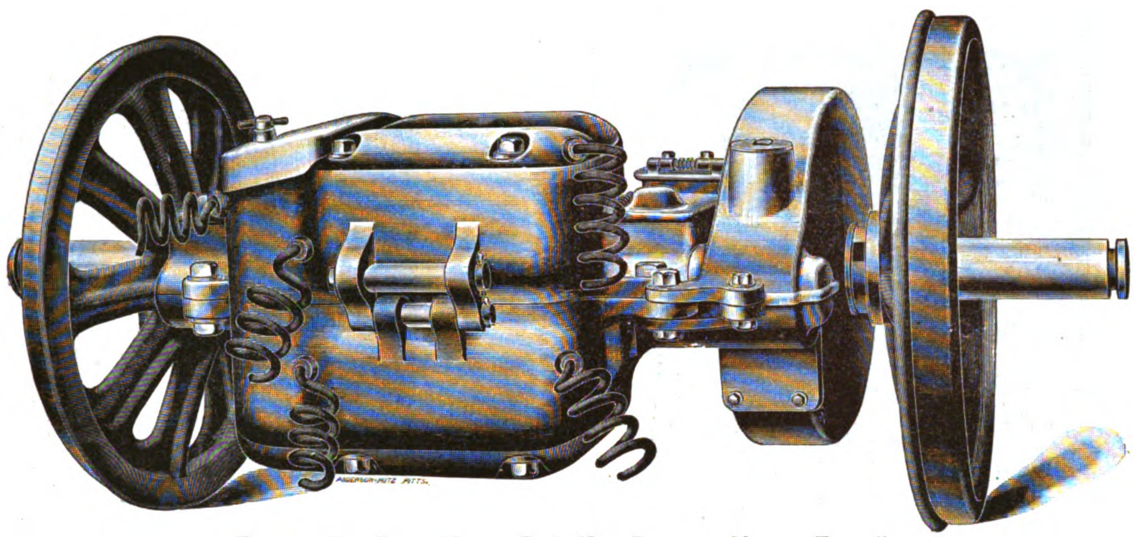


FIG. 1.—THE STEEL MOTOR CO.'S NEW RAILWAY MOTOR, TYPE C3.

30 horse-power and is designed to exert a horizontal effort or drawbar pull of 1,000 pounds, continuously, without heating, or sparking at the brushes. Much greater power can be developed for short periods of time without injury. Low cost of maintenance and accessibility of all parts are the primary objects of the design.

The frame or body of the motor is of low carbon cast steel, ensuring maximum power for minimum weight. The bearings

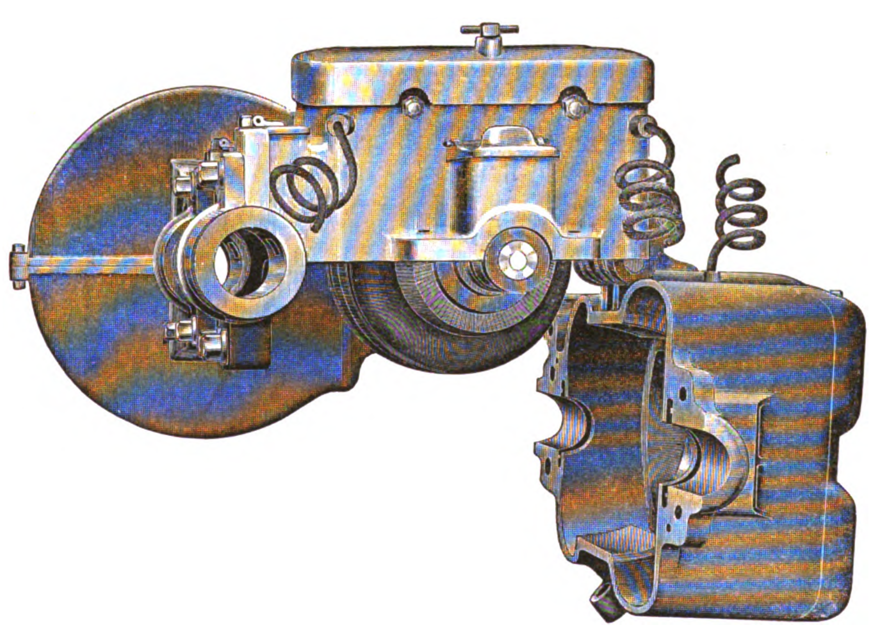

FIG. 2.—THE STEEL MOTOR CO.'S NEW RAILWAY MOTOR, TYPE C3.

for both axle and armature are contained in the same casting, ensuring perfect alignment. The frame is parted through the center and suspended so as to allow of the removal of the armature from below. The top and bottom of the motor frame are also separable and contain the upper and lower pole pieces, to which are securely attached the field coils, making it possible to remove either without disturbing any other part of the motor.

Phosphor bronze axle bearings are supplied with the motors of any desired diameter under 4¼ inches. All bearings are lubricated with grease and malleable iron covers, closed by springs, excluding all dirt from the grease pockets. Openings are provided between the armature bearings and the motor frame proper, through which all surplus grease falls to the ground. A malleable iron door or cover placed in the top of the motor over the commutator, facilitates inspection and the replacing of brushes. This opening is of ample dimensions to allow the removal of the brush-holders and yoke when desired. The motor is designed for nose suspension, the axle being relieved of all unnecessary weight, which is supported by the flexible connections with the truck.

The armature core is of the drum type, built up of thin discs of Swedish iron, with soft steel heads, and is pierced with holes parallel with the shaft for ventilation.

The shaft is of hammered steel 3⅞ inch diameter, and provided with tapered seat for both commutator and pinion. The bearings are of large diameter and great length, ensuring cool running. Flanges or collars are keyed to the shaft and run in the open spaces between the motor frame and bearings. These prevent end motion of the armature and are also an extra safeguard to prevent oil or moisture from entering the motor frame.

The armature winding consists of machine wound coils, thoroughly insulated by a special compound and a double layer of insulating material. The slots of the core are also lined with troughs of special insulating material which en-

sures their easy removal no matter how long in service. The coils are laid in the slots of the core, well below the surface. mutator, which effectually prevents the coils rising due to centrifugal force when running at excessive speeds. The coils

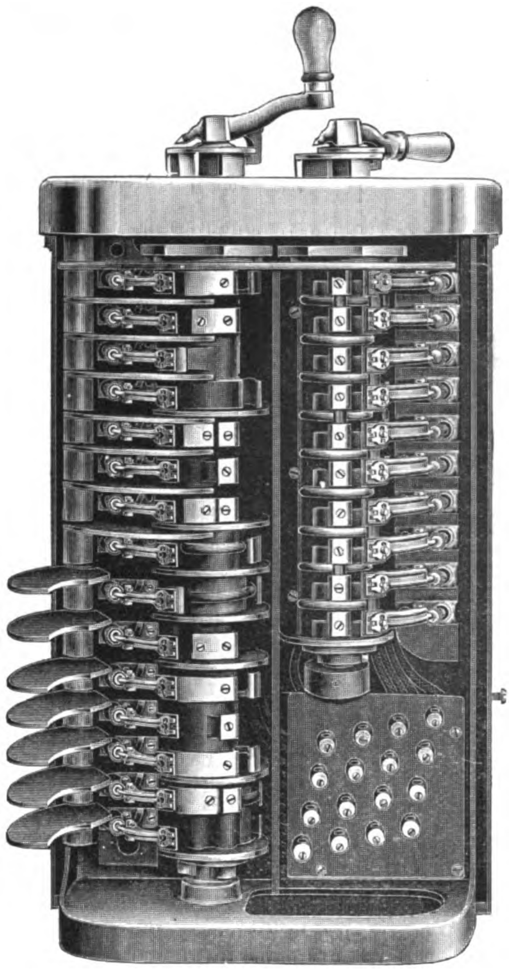

Fig. 3.—Steel Motor Co.'s Controller, Type C3.

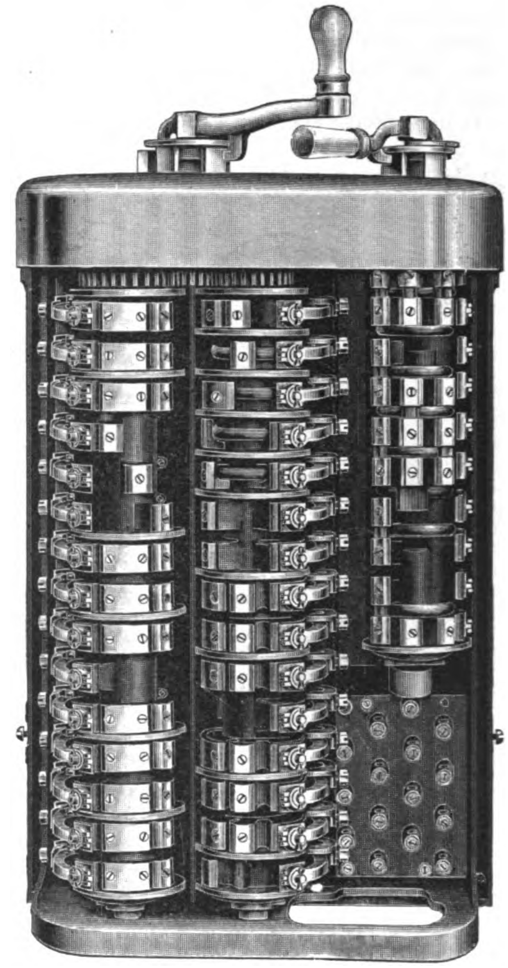

Fig. 4.—Steel Motor Co.'s Controller, Type D2.

The remainder of the slot is filled with a hard wood strip, and the whole is securely bound with German silver wire. are placed so that the heads do not interfere with the ventilation of the core.

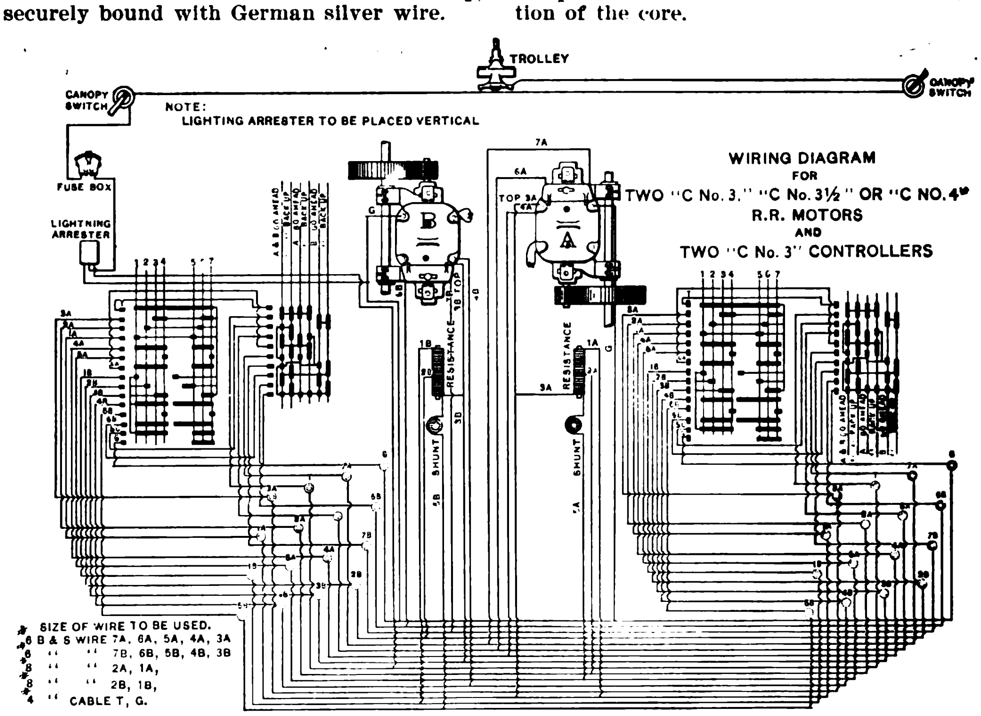

Fig. 5.—Car Wiring Diagram for Steel Motor Co.'s Motors and Controllers.

The heads of the armature are covered with canvas, thoroughly varnished to exclude moisture and dust, and a brass ventilating shield is placed on the head, opposite the commutator.

The commutator is a malleable iron shell filled with drop forged copper segments and insulated throughout with mica. The segments are locked in place by double tapered collars.

The design allows the greatest possible wear, and eliminates all possibility of the segments becoming loosened when partially worn. The leads from the armature coils to the commutator are doubly insulated by specially prepared tubing, and are soldered into slots milled in the commutator segments.

The field coils, two in number, are wound on insulated brass spools. These spools are placed upon and fastened to the upper and lower pole pieces, the poles in the horizontal planes being induced. The top and bottom of the motor, to which the field spools are fastened being detachable from the motor frame, either field coil can be removed independent of all other parts of the motor.

The brush holders are adjustable together or independently. The carbon brushes are 3½ inches long and have a bearing of 2½ inches on the commutator. The tension of the pressure spring is uniform throughout the length of feed, and the arrangement of the levers permits the hammer block to be thrown back when removing or replacing brushes.

The gears are of cast steel and the gear casing of malleable iron, accurately fitted. The special feature is the small removable section, just below the pinion, which is all it is necessary to remove when taking out the armature.

The C-3 controller, illustrated in Fig. 3, is of the series-multiple type, designed for use in connection with two motors of 25 to 50 horse-power each. The controlling cylinder consists of iron sections, placed upon an insulated shaft and insulated from each other by vulcabeston discs. Copper contacts which can be readily replaced, are fastened to these sections.

The finger board contains the stationary contacts of the company's well known type, with loose contact shoe enabling self-adjustment to any contour or inequality of cylinder, ensuring at all times the greatest possible area of contact. These fingers can be thrown back out of the way when inspecting or repairing the controller.

The distinguishing feature of this controller is the combined reversing and motor cut-out switch, which is operated by the reverse handle, the movement of which, to the points plainly marked on the index, enables both motors together, or either of them independently, to be run in either direction.

The D_2 controller, Fig. 4, is of the series-multiple type designed for use with very heavy motors, and with four motors to the car. Two controlling cylinders, moved simultaneously by means of pinion and gears, are employed, so connected that one motor or set of motors is operated by each cylinder. These cylinders are of practically the same design as the type C-3, but with contacts of much greater area and carrying capacity. This applies also to the finger contacts. Contact is broken through 28 points simultaneously, reducing the arc to a minimum.

The combined reverse and cut-out switch is the same as described in the type C-3 controller, but larger and of greater capacity. Both controllers are provided with locking devices, which prevent the motors being reversed, except by first sending the current through a proper resistance, also with indexes which plainly indicate the different points of contact.

The accompanying diagram, Fig. 5, illustrates the company's method of wiring cars for two C3, C3½, or C4 railroad motors, and two C¾ controllers.

THE GIBBS MOTOR ALARM FOR ELECTRIC CARS.

ONE of the uncertainties which harass the operators of electric cars is as to the exact time to renew the armature bearings. This is of considerable importance, for if not attended to in time, the armature drops down on to the field magnets and by friction with the pole piece causes a short circuit and burn out. Of course periodical inspection will reveal the proper time to renew bearings, but a simple device which will indicate the fact automatically, has a distinct value in itself, as well as saving the cost and time required for inspection.

An automatic motor alarm of this kind has been designed by Mr. W. A. Gibbs, of Pawtucket, R. I., and has been in successful operation for a year past on the cars of the Providence (R. I.) electric railway.

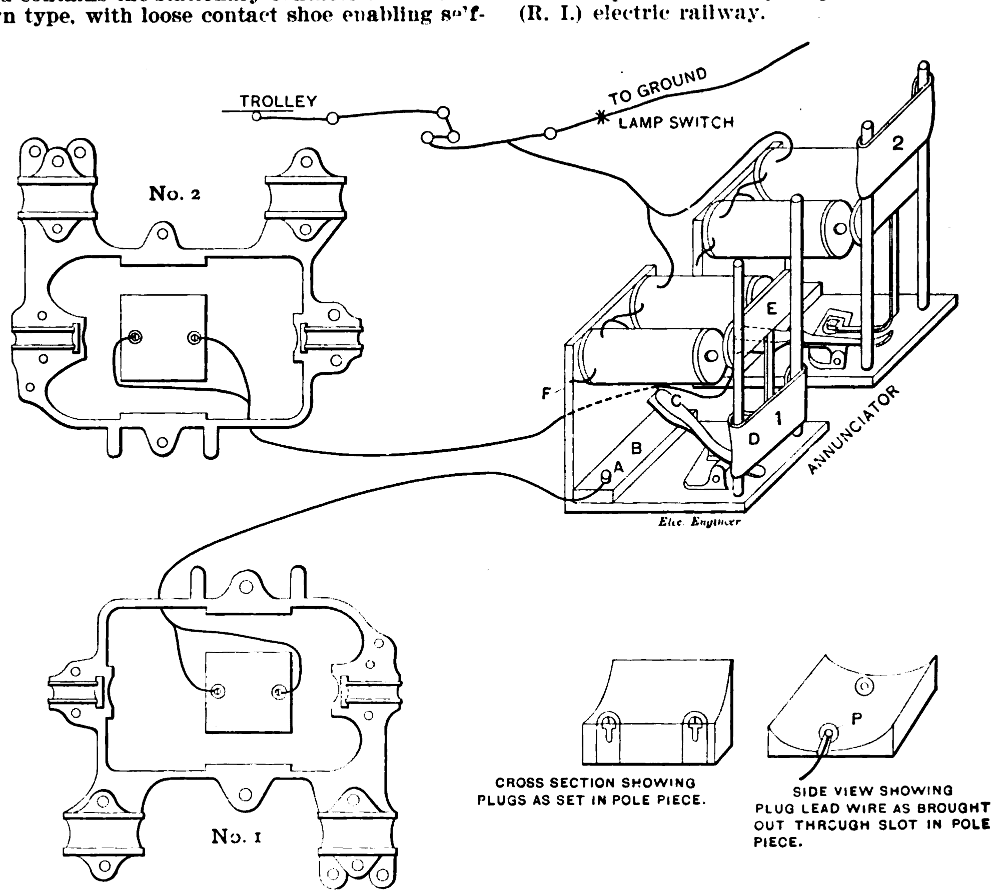

FIG. 1.—THE GIBBS MOTOR ALARM FOR TROLLEY CAR ARMATURE BEARINGS.

Our illustration, Fig. 1, shows the manner in which the Gibbs alarm is applied, Fig. 2, showing the annunciator, the drops in which, one for each motor armature, indicate, when exposed, that the bearing is worn down to its limit.

In order to obtain the necessary contact to close the annunciator circuits, plugs are inserted in the lower pole piece. These plugs, shown at P, consist of a screw set into the end of a ¾-inch round piece of fiber, so that it will come just under the surface of the fiber, about 1-32 inch.

The annunciator circuit is brought in through a hole in the side of the fiber, and clamped under the screw. The top of the screw is then covered with sealing wax, so that the contact in the plug is entirely inclosed in insulation, being thus dirt and water tight. The plug is set projecting out from the pole piece just far enough to allow the dropping armature to wear off the top down to the contact screw. The core of the

iron clad armature, or grounded band of other types, closes the circuit to ground and the annunciator drop falls. The plug simply needs to be again covered with sealing wax for another operation.

The annunciator drops are placed in a small box, Fig. 2, and the drops are only visible when down, that is, when the armature is rubbing. The wiring of the alarm circuit is clearly indicated in Fig. 1.

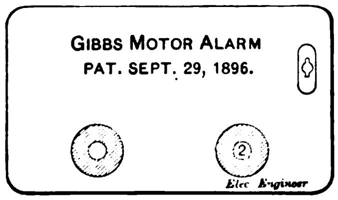

FIG. 2.—GIBBS MOTOR ALARM ANNUNCIATOR.

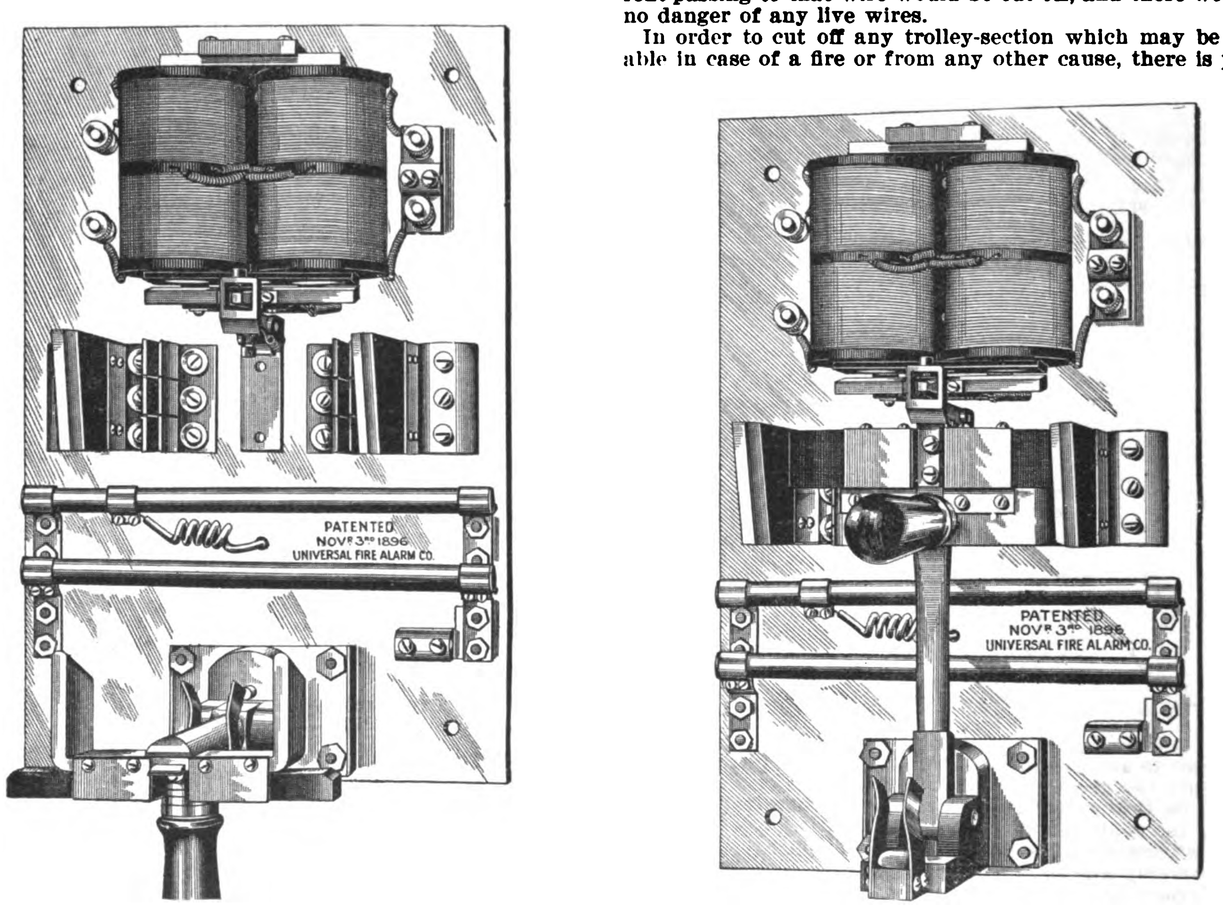
It must be apparent that a device of this kind not only protects the armature but also permits of a saving in the cost of bearings as the later may without fear of trouble, be run to their full wearing limit, and, as stated above, even where periodical inspections are made it will constitute an additional safeguard.

THE ROWAND AUTOMATIC CUT-OUT FOR TROLLEY WIRES.

THE danger involved in the breaking and falling of live trolley wires makes it desirable to provide a positive acting means for automatically cutting off the current from the trolley wire as soon as it parts. A highly ingenious and simple device of this nature has been designed by Mr. Lewis G. Rowand, electrician of the Universal Fire Alarm Company, of Camden, N. J., and is illustrated in its open and closed positions in the engravings, Figs. 1 and 2.



FIGS. 1 AND 2.—THE ROWAND AUTOMATIC CUT-OUT FOR TROLLEY WIRES.

The operation of the cut-out will be readily understood by an inspection of the accompanying diagram, Fig. 3. Here A is the main or trunk wire of an electric road; B, the trolley-section. The return of this trolley-section B before passing to ground passes through the electromagnet C, which has double winding, the windings being in opposite directions. The trolley-sections B pass to one of these windings. From the magnet C a wire c connects to ground.

A wire, D, also connects with the trunk line, the trolley-section B and wire D having a common connection with the trunk line A through wire d. The wire D is connected with the opposite winding of the magnet C to that to which wire B is connected. It will thus be seen that B and D are two circuits in multiple, having a connection d with the source of current supply (trunk A) common to both, each circuit having a winding of the magnet C in circuit, but the windings being opposite, so that normally the currents passing through the magnet C from the two circuits neutralize each other, and the magnet is not energized.

Upon the connection d, common to both circuits B and D, is placed a switch E, which is normally closed, being controlled by the armature c' of the magnet C, the arrangement being such that when the magnet is energized the armature acts to operate the switch to open the circuits upon the portion d. Upon both the circuits of the wires B and D are placed resistances F to prevent unnecessary current passing through the magnet.

The practical operation of this device will now be understood. Under ordinary conditions the current passes from the trunk line A both through the circuit B and circuit D. The circuit B is the trolley circuit and feeds the trolley cars. The current from both circuits B and D passes through the magnet C, but passing in opposite directions does not energize it. Now, in case the trolley-wire B, should break, the current will no longer, so far as that circuit is concerned, pass through the magnet C. The consequence is that the current from the circuit D, passing through the magnet C will energize it, and the magnet will open the switch and cut off any current passing to either the circuit B or the circuit D. As a consequence, if for any cause a trolley-wire should break, no matter how many cars there were upon the circuit, at once the current passing to that wire would be cut off, and there would be no danger of any live wires.

In order to cut off any trolley-section which may be desirable in case of a fire or from any other cause, there is placed upon either circuit B or D (as shown it is circuit D),at a point contiguous to the magnet C, a switch G, having a ground connection, which may be operated by hand, so as to short circuit the wire D to ground, which, of course, will have the effect of preventing it passing through the armature C,, and therefore, as in the case of the broken wire, the magnet C will

become energized and open the circuit to the common wire d. The same thing may be accomplished by a switch which, as shown, is short-circuited around the resistance, as shown at G'.

In many cases it is desirable that the least possible amount of current should pass to the magnet C through circuits B

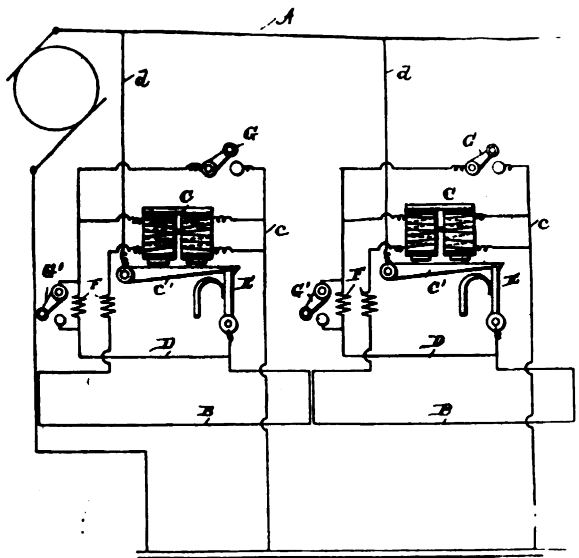


FIG. 3.—THE ROWAND AUTOMATIC CUT-OUT FOR TROLLEY CIRCUITS.

and D. This is accomplished by making the resistances F very high. In this case when the magnet is energized it would be but slightly, and hence might not act upon the armature c'. This contingency is provided for by a simple device which cuts out the resistance and sends the full current directly into the magnet which then acts with full force on the armature and opens the switch.

BOSTON STEAM LINES TO ADOPT ELECTRICITY.

A SPECIAL dispatch from Boston of Dec. 8, says: The plans of the Boston Terminal Co., which is constructing the new union station contemplates a new departure in railroading. These plans provide for the joint handling of electric and steam traffic. In some respects the new station may be considered as being an electric road station, for it will provide for the handling of the suburban traffic south of Boston, amounting to hundreds of millions of passengers annually, by means of electric trains.

The use of electricity on the Nantasket branch of the New York, New Haven and Hartford Railroad was simply an entering wedge. The system has so completely demonstrated its efficiency that next year the Dedham branch will be equipped with the third rail system, and by the time the new station is completed, it is expected that the entire suburban business of the New York, New Haven and Hartford will be handled by electric trains, the company being able to run a greater number of trains with less power than is required under the present system.

At present only the general outlines of the scheme for the extension of the electric service and its use in connection with the new Union Station are complete. But the officers of the New York, New Haven and Hartford are not only confident of the success of electricity as a motive power for suburban trains, but look forward with some confidence to the ultimate extension of the electric service to the through trains.

The New England and Old Colony roads will have the same station facilities at their disposal, and while the New England has not considered the matter seriously, some of its officers expect to see that road take advantage of the facilities which the new plans for the station provide, and use the third rail system on the New England suburban tracks.

If the experience of these roads shall warrant, there is little doubt that the Boston and Albany will take advantage of the system also, for its suburban circuit service.

B. & O. PASSENGERS CARRIED.

The total number of passengers carried on the entire system of the B. & O. R. R. for the fiscal year ending June 30, 1896, was 8,567,194, an increase of 359,586 over the corresponding period for 1895.

The total number of passengers carried one mile was 299,616,039, an increase of 11,790,117 miles.

MERIT SYSTEM ON THE CANAL AND CLAIBORNE ROAD, NEW ORLEANS.

Mr. George H. Davis, a gentleman largely interested in the Claiborne road, has established an innovation in New Orleans in the form of a civil service system among the employés. The groundwork of this plan is that all employés must go through the regular channel to secure promotion. A man is first put in as an "extra," and if he proves efficient he is given a regular position when a vacancy occurs and he is the first on the list. There is no deviation from this rule, and a man who desires to enter the employ of the company knows that no favoritism will be shown in the way of giving extra work to favorites or putting in new men in regular positions while older "extras" have to wait. Under the system there is no such thing as fining a man for any slight infractions of the rules of the company or upon the pretext of some overbearing official of the company. In lieu of fines a system of "merit" and "demerit" marks is employed. Under its operations if an employé violates a rule he is charged with a given number of "demerit" marks, according to the gravity of the offense. When he is faithful and efficient and endeavors to advance the interests of the company he is credited with "merit" marks. At intervals the "merit" and "demerit" marks are compared, and if it is found that an employé is too indifferent in his work to be a safe man to have in the employ of the company he is discharged. Under this system a steady, faithful man, knows that he is assured of steady employment and good treatment, while the company is rewarded by securing the services of the better class of workmen.

The officials of the company find that the system works very satisfactory for the road, while it also redounds to the benefit of the men. Civil service on the same lines has been tried with much success on some of the electric roads of the East, but the Claiborne management is the first to introduce it in the South. It is thought its operation will have a great tendency to create a better feeling between the road and their employés and will go far toward preventing strikes.

THE ELECTRIC PLANS OF THE LONDON "UNDERGROUND."

The Metropolitan District Railway has practically decided to adopt that plan for an express line underneath its present road from Hammersmith to "the city." A recent report of Sir Benjamin Baker to the Shareholders' Association, states that the projected line is five miles long. At the Charing Cross Station the platforms will be 63 feet below those of the present district railway, or 78 feet below the street level. The depth will be 18 feet greater at the Mansion House Station. There will be both elevators and stairways at the stations. The estimate of cost for double tunnel, shafts, permanent roadway and sidings, stations, and such land and easements as may be required, with 10 per cent. added for contingencies, is $5,000,000; for electrical installation, rolling stock, repair shops, and other equipment, and for professional charges, parliamentary and other expenses, and interest during construction, $2,250,000, or in all about $7,500,000, for the five miles of completed and equipped road. The tunnel construction is practically on the Greathead plan.

TROLLEY LINE TELEPHONE ACCIDENT IN LOS ANGELES.

A car conductor on the Los Angeles Electric Railway went to use one of the telephones along the line and call up the dispatcher, when he received a fatal shock, due to the fact that an electric lighting circuit had fallen upon the telephone wire about two miles away. It appears that the conductor in his hurry had seized the telephone by its metal contacts; otherwise he might have escaped the effects of the short circuit. The line had previously given evidence of being in trouble.

LARGE CONNECTICUT TROLLEY PROJECTS.—Various trolley railroad projects, which, as their promoters say, will be before the coming Legislature of Connecticut, either for new charters or for extensions of old ones, already involve about 100 miles of new trolley track, of which about eighty miles would parallel steam roads. From several sources come reports that the New Haven steam railroad company will try to dispense with lobby agents at the coming session, and this plan, it is stated, has led to schemes of those agents to organize a combination in favor of the electric roads.

CONTENTS.

BOILER EFFICIENCY AND SMOKELESSNESS WITH LOW GRADE FUELS.

ELECTRIC central station requirements have put the builders of steam engines on their mettle, but the boiler makers have also been stirred to put forward their best efforts to meet the exacting requirements. Nevertheless, there would seem to be much that can be improved in this important adjunct, if we may assume as well taken the criticisms which Mr. William H. Bryan, the well-known steam expert of St. Louis, launches against general modern boiler practice. In a paper read before the Engineer's Club of St. Louis, that gentleman points out several discrepancies in the methods of boiler testing now in vogue and suggests several modifications in the code as laid down by the Committee of the American Society of Mechanical Engineers, about ten years ago. Principal among these is the expressing of the efficiency of the boiler in "equivalent evaporation per pound of coal," which is characterized as meaningless unless one knows all about the coal. Reducing to "pound combustible," is easily liable to error, particularly in low grade fuels, running high in ash and making bad clinkers, which quality largely predominates throughout the Mississippi Valley States and the West. To remedy the defect it is suggested that in every boiler trial the coal be carefully sampled and immediately submitted to chemical analysis and calorific determination. With this data at hand a ready comparison can be made as to the work actually done by the pound of coal under the boiler, and the efficiency percentage thus secured. Against the criticism that coal calorimeters are not all that they might be and that they are also liable to lead to erroneous results, Mr. Bryan urges the fact that the constant improvements being made in them must soon lead to their practical perfection.

Referring to the common necessity for boiler trials arising from boiler contracts, which include specific guarantees of performance, attention is drawn to a practice similar to that obtaining in the United States Navy contracts with shipbuilders, namely, the adding of a bonus for each fraction of the boiler performance above that specified in the contracts. In a recent bid for boilers, for example, the bids were one-third lower than they could usually be purchased in the open market, the contractors nevertheless expecting in the end to realize the full selling price, or more, by exceeding the maximum performance called for in the contract.

But what appeals to the steam user most forcibly in Mr. Bryan's paper is a tabulated statement of results of a number of boiler trials undertaken by him, nearly all made with ordinary Illinois coals. They represent the widest extremes of practice, including many badly designed and overworked boilers. Nevertheless the figures are quite interesting. They indicate, among other things, that the best improved furnaces increase the efficiency over 25 per cent. above the best common setting under a tubular boiler and about 15 per cent. under a water tube boiler. It is also shown that the best water tube boiler does over 15 per cent. better than the best return tubular with ordinary setting, the increase, however, under average conditions, being about 20 per cent.

The matter of smoke prevention was also a subject of investigation by Mr. Bryan, whose tests show that the improved furnaces have reduced the smoke on an average fully 80 per cent. He also shows that smoke averaging less than 1 per cent. is not only possible, but is being secured regularly in every day service in quite a number of large steam plants in St. Louis.

It would take us too far to discuss all the details of this most valuable and interesting paper, but we cannot forego mention of Mr. Bryan's strong advocacy of the employment of fans for producing the required draft in boiler furnaces and the consequent abandonment of tall chimneys. To quote Mr. Bryan, "it may be safely stated that in this year of our Lord, 1896, the building of tall chimneys to secure draft, simply advertises the owner's lack of familiarity with modern improvements, or his want of confidence in results easily demon-

strated." Of course, there are exceptions to this rule, where the plant is small, fuel comparatively inexpensive and money not available, or where other considerations require the gases to be discharged at considerable elevation. As a matter of fact, the most advanced electric central station engineers have long since recognized the particular advantage of forced draft and have adopted it in their practice, and when one stops to consider the variable nature of the load in lighting and railway practice, coupled with the sluggish action of a chimney, it is a matter of surprise indeed, that more general recognition has not been accorded to this important detail in steam generation. We believe, however, that for large central stations of the future, the tall chimney is out of favor.

A NEW GREAT WATER POWER DEVELOPMENT.

WE think it may be safely asserted that no art or science has served in a greater degree to bring out the latent mental forces of man than has electricity. The tremendous activity in this field for the past twenty years has resulted in the evocation of a great volume of new ideas, a goodly proportion of which have been turned to useful account and have been the basis of new industries that have added millions upon millions to the material wealth of all the civilized nations of the earth. But it is not man alone whose latent forces have been called into play by the progress of electrical development. Nature also has been drawn into the new activity and its own latent powers made available in a way and to an extent which the wildest enthusiast would hardly have dared to foretell. The utilization of the large water powers at Niagara, Lachine and elsewhere is now an old, though ever interesting story; but the announcement that a new water power of enormous proportions is about to be developed will create surprise in electrical circles. As mentioned elsewhere in this issue, a new project is well under way for tapping the St. Lawrence to the tune of a probable 200,000 horse-power. But what is most remarkable in connection with this new enterprise is the phenomenally low cost of its development. The estimate of one million dollars, for the cost of delivery of the water to wheels aggregating 100,000 horse-power, that is, at the rate of $10 per horse-power, is so low that the cost for power delivered may be expected to be placed at a correspondingly low figure. With this new power available there is little doubt that America must eventually become the center of the newer electro-chemical industry in which the cost of power enters as the principal item in the manufactured product. Already this country is exporting all the calcium carbide, for example, which the present existing plants are capable of turning out, and the demand is far in excess of the supply. This is only one of the many products which these powers will serve to produce. The alkali industries will probably be next in line and side by side with them the chlorine industry and its many derivatives. The mere mention of these few, coupled with the known enormous quantities of the alkali and chlorine products consumed throughout the world, would seem to indicate that but a comparatively short time will elapse before all the present great water power undertakings will be fully utilized. There will thus be room for all and the outlook may well stimulate search for further available powers.

THE REALITY OF BETTER TIMES.

WE are in receipt of a letter from Montana, in which the writer, at a mine, referring sarcastically to some of our recent promises of better times should this country declare for sound money and an honest dollar, says: "Please ask the editors to write me when the wave of prosperity strikes us, so that we will be prepared for it."

This compels us to advise our friend at once that the better times have actually come, and have been coming ever since election day. As to the wave striking Montana, that is another matter, for we note mention in the various financial papers of a great disinclination on the part of investors to place money in localities that voted solidly for a depreciated currency, their fear being that they might not get back as much as they loaned or invested. As to the rest of the country, and as to the electrical industry in particular, we can only say that there is an activity the like of which we have not seen in many years. In the departments of electric lighting and electric railway and power work, there is more new business in sight than at almost any other period in the whole of the past ten years. Plans are now being made and negotiations closed for new plants and extensions running well up to $100,000,000. We know of two engineers alone who are dealing with nearly $30,000,000 of new work, all to be done as soon as it can be got at. When we turn to buildings, the new electrical work is sufficiently indicated by the fact that in some three architects' offices, in New York City, about $40,000,000 of work is now on the drawing boards. Nor is everything in the future, for there is hardly an electrical concern that does not report a present gain of 5 or 10 per cent., or even more, in its trade.

If we had a stable currency, and a modest, moderate foreign policy, there would be no question as to the magnitude of the wave of prosperity now rolling in. But the wave is here, and all the harm we wish our Montana friend is that it may hit him also.

ARC LIGHTS ALONG RAILROADS.

WE have already commented on the plans of the Consolidated (New York, New Haven and Hartford) R. R. for using electric motive power on many of its branches and short lines, and it is quite in keeping that further plans should now gain publicity as to lighting stretches of the road by lines of arcs. This is not an altogether new idea, the Pennsylvania Railroad having tried it, but its general adoption by a great system is certainly new. It is said that the engineers of the Consolidated believe that four arc lights placed properly will light a mile of straight road so thoroughly as to preclude any possibility of accident from the rare causes that the block system cannot take care of. We do not know upon what experience or data this calculation is based, but venture the opinion that there would be no harm in having the lights a good deal closer, especially as it would be necessary to keep the direct beams out of the eyes of the men running the locomotives. It will be remembered that the pilots on the East River objected most strenuously to the arcs on the Brooklyn Bridge and insisted on being shielded from their direct rays, and we are inclined to think that locomotive engineers will feel just the same way. But there is no question as to the pleasant and safe travel along a road lit from one end to the other as brilliantly as a city boulevard, and in view of the double use of the power house, the cost should not run very high. As a matter of fact, the power house at Baltimore for the big tunnel locomotives does a good business in supplying and selling current for other purposes, inclusive of lighting and running street cars, and the same conditions will apply in New England, which is to-day little more than a big city strung along a railroad track.

STEALING CURRENT.

MORE than one report and inquiry of late leads us to believe that the practice of stealing current is on the increase, and that magistrates and lawyers are a little puzzled how to deal with this novel form of offense. In one case, from Germany, it is stated that the judge let off the offender on the ground that electric current is not property! While ready to admit the non-corporeal nature of the commodity, it seems to us that anything capable of being measured is capable of furnishing evidence of its own presence, or of its having been abstracted by persons to whom it does not belong. Besides, circuits must be tampered with in order to get the "juice" from them, and surely that offense is well within the scope of the law, as it exists. Gas is hardly more tangible than electricity, yet a man who burns gas not belonging to him, or cutting into pipes to get the supply, is speedily punished. Wire tappers, too, are disposed of in pretty short order, in spite of the fact that they fall far short of using the current itself, as do those who tap for the purpose of getting light and power surreptitiously. In fact, we think that any of these newer cases if properly handled would be found well within the competence of existing laws, and that convictions could be obtained. We shall, however, be glad to be advised by any of our readers as to whether specific laws on the subject exist in their respective states. If not, it might be well for the National Electric Light Association to have a law drafted, which can be taken care of by those interested in each State, and thus placed upon the statute book.

POWER TRANSMISSION.

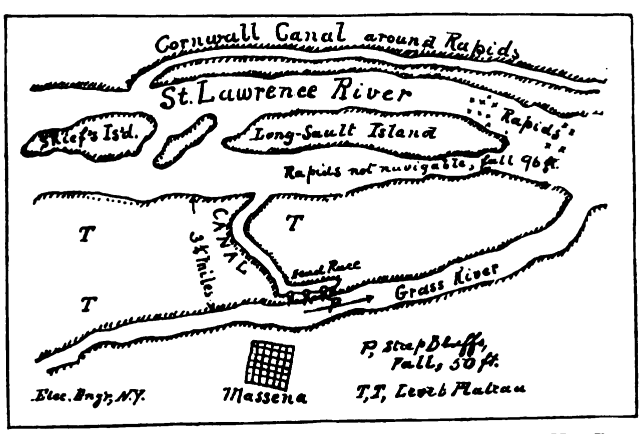
100,000, TO 200,000 H. P. TO BE DEVELOPED ELECTRICALLY AT MASSENA, N. Y.

THE Great Lakes and their outflow, the St. Lawrence River, have served as sources of power which have been developed at Sault Ste. Marie, Niagara and the Lachine Rapids, but strange as it may seem, the same water flowing in the St. Lawrence has only recently, one might say almost by accident, been discovered to be capable of delivering a still further enormous amount of power and, what is equally important, at a cost for development which is exceedingly small.

The location of this favored spot is in the town of Massena, in St. Lawrence County, close to the northern boundary of New York State, about 40 miles southwest of Montreal. At this point, as shown on the accompanying map, the Grass River, a considerable stream, flows parallel to the St. Lawrence, only three miles away and discharges into the latter, seven miles below.

In this distance the St. Lawrence falls about 100 feet over the Long Sault Rapids, but the Grass River only falls about 50 feet in this distance so that its water level at Massena is about 50 feet below that of the St. Lawrence at a point three miles due north. It is this favorable condition which has been availed of by the promoters of the enterprise.

Nature has also coupled with the above mentioned available facilities other rather remarkable advantages. Thus a level plateau, marked T, T, on the map, entirely free from rock, extends from the high bluffs on the north shore of the Grass River to the St. Lawrence. A canal only 3½ miles long will bring the St. Lawrence's water to the limestone bluff on the



MAP SHOWING PLAN OF DEVELOPMENT FOR 200,000 H. P. AT MASSENA, N. Y.

north bank of the Grass River, where it will have a sheer fall of 50 feet to the river below which is an ample and natural tail race to take the water back to the St. Lawrence. To get 100,000 horse-power all that is required is a surface canal 3½ miles long, about 200 feet wide, capable of carrying 1,000,000 cubic feet of water per minute.

Mr. John Bogart, consulting engineer of the company, has placed the cost of the canal for developing 100,000 horse-power at less than a million dollars, which means an installation cost for water power of $10 per horse-power, a figure so low that the assertion invites criticism, but the facts, it seems, cannot be disputed. Other competent engineers support Mr. Bogart's statements.

The present outlook is that the power will be nearly all used on the spot. Wood pulp mills will take a considerable share of it, but it is extremely probable that 50,000 or 75,000 horse-power will be required for the manufacture of electro-chemical products.

Lieut. F. Jarvis Patten, who is now at work designing the power plant proposes to install 10,000 horse-power dynamos connected direct to the spindles of turbines of that output, which, under the comparatively low pressure used, will involve but little difficulty.

Besides the natural advantages of the topography of the region for power purposes, the digging of the power canal will put the mills and other works at Massena in communication by water with Buffalo and the Great Lakes, while the distance by rail to New York is less than nine hours.

The promoters of this new and highly important power enterprise are Messrs. Stewart & Co., of New York.

A NEW METHOD OF SPEED CONTROL FOR ELECTRIC MOTORS.

BY PROF. W. A. ANTHONY.

AS I was unable, on account of active engagements, to be present at the last meeting of the American Institute of Electrical Engineers, when the speed control of electric motors was under discussion, I take the opportunity to present, through the columns of "The Electrical Engineer" some views of my own on the subject.

The H. Ward Leonard system is theoretically an ideal sys-

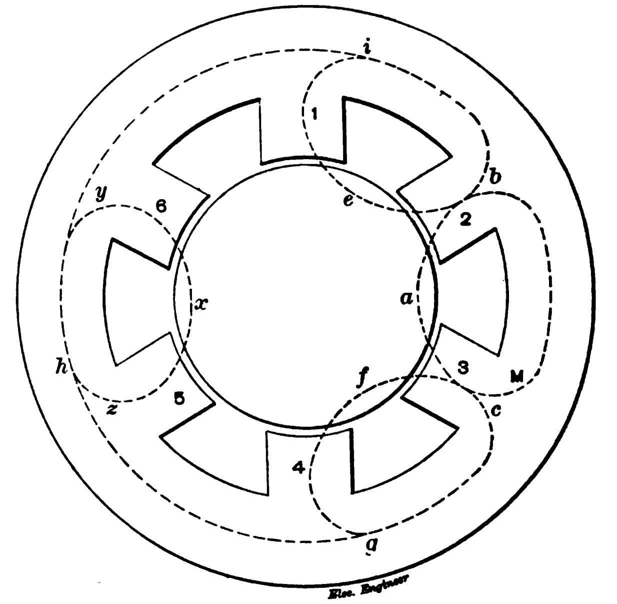


FIG. 1.

tem, giving perfect control of speed from zero to a maximum without waste of energy, but it has the disadvantage that it requires a dynamo for each motor, and that that dynamo does spark when its field is weak.

Regulation of speed by variation of field strength of the motor has the same advantage of involving no waste of energy, but it has had the disadvantage that the increase of speed that could be obtained by weakening the field, was limited to a comparatively small percentage variation, because the weak field has not the power to control the sparking at the commutator.

It is well known that the control of sparking at the commutator depends largely upon the density and stability of the magnetic "fringe" at the pole corners. It is well known, too, that this fringe disappears very rapidly as the field is weakened, and that to maintain it intact the field magneto-motive force must be kept well in excess of the armature reaction.

It occurred to me that if in a multipolar machine having a "two path" armature winding, wherein the electro-motive forces developed by the several pairs of poles were added together to make up the total e. m. f. of the machine, one

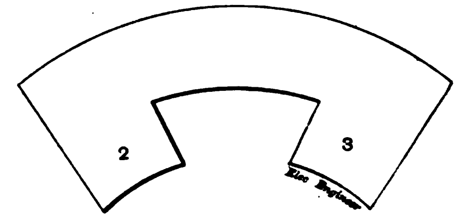

FIG. 2.

pair of poles—a north and a south—could be varied in strength without varying tne others, the magnetic fringe at the corners of the unvaried poles would remain, and a much greater variation of speed could be effected than would be possible if the field as a whole were weakened.

Let Fig. 1 represent a six-pole motor, wound as usual with a field coil on each pole. Assume that all the coils are excited. There will be an equal magnetic flux through each of the circuits a b c, e b i, f g c, etc., Fig. 1. Now suppose the

circuit through coils on pole cores 1 and 4 to be broken, and consider what will happen on the supposition that the "yoke" connecting the pole cores is very heavy and presents but a very small magnetic reluctance. The magneto-motive force tending to carry the magnetic flux through the circuits 1 and 4 no longer exists, but the lines which before went through 1 and 4 are by no means lost to 2 and 3, since they may still find their way by the path i h g of very low reluctance through the yoke. Hence, if the yoke be sufficiently heavy the poles 2 and 3 will be hardly at all diminished by cutting the coils 1 and 4 out of circuit, or even reversing them. The same is true of poles 5 and 6.

It would be easy, if necessary, to so design the machine that a b c should form one circuit and x y z another, both entirely independent of the circuit through 1 and 4. Poles 2 and 3 and 5 and 6 might, for instance, be made as separate castings, as shown in Fig. 2. Poles 1 and 4 might then be connected by yokes, which would serve also as supports for the armature bearings. Poles 2 and 3 and 5 and 6 could then be magnetically insulated from 1 and 4, so that no change produced in the magnetic strength can in any way affect the strength of the remaining poles.

It is, however, unnecessary to go to the extent of magnetically insulating the poles which are, from those which are not, to be varied. A machine made upon the ordinary plan, but having a considerably heavier connecting yoke, will serve to secure all the necessary independence between the poles.

In a six-pole machine the speed with one pair of poles cut out will be about one and a half times, and with that pair of poles reversed will be about three times the speed with all poles active, and, of course, all intermediate speeds may be obtained by gradually cutting down the current in the coils by means of resistance before cutting them out altogether and then reversing through the same resistance, which is then gradually cut out.

Machines having 10 or 14 poles will be susceptible to much wider ranges of speed variation than can be realized with one of six poles.

It is possible to apply the same method of control to multipolar machines having one common field coil for magnetizing all the poles.

It will, of course, be understood that where constant torque is required at all speeds, as is approximately the case for elevator or street car service, for running printing presses, etc., the capacity of the motor is limited by the conditions at high speed. At the low speed the capacity would be unnecessarily small, the torque being almost inversely proportional to the speed. Where constant power is required, as is approximately the case for machine tools, such as lathes, boring mills, etc., the motor would fulfill the requirements at all speeds.

The range of speed that it is possible to obtain by this method of control is certainly very much greater than has been possible by varying the field strength as a whole, and I believe it will be found an exceedingly valuable method in most cases where variable speed is required.

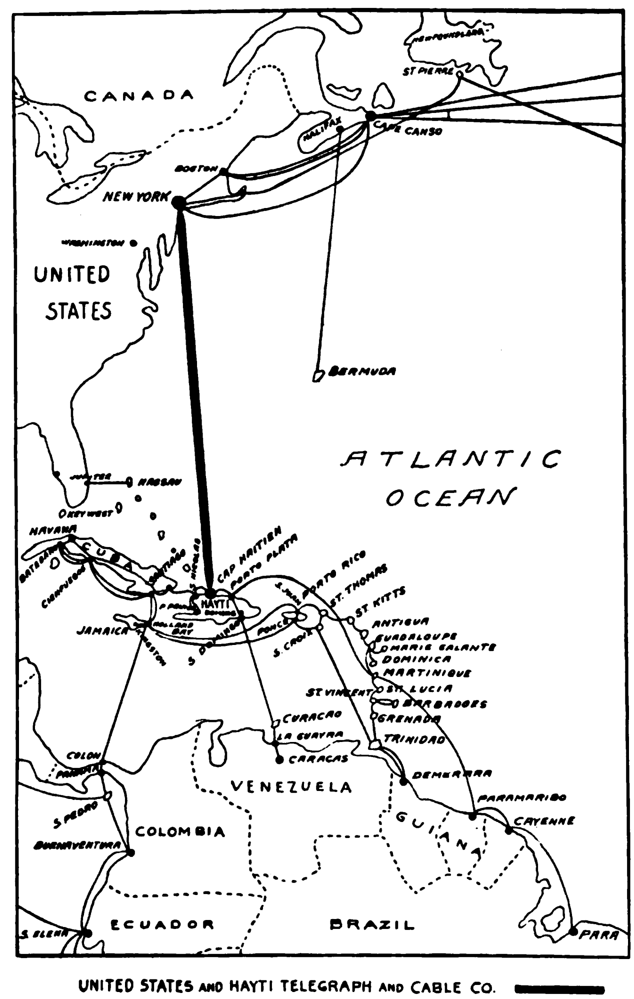
POWER TRANSMISSION AT CHEBOYGAN, MICH.

Mr. J. S. Loomis, superintendent of the Cheboygan Electric Light and Power Company, sends us some interesting data as to the power transmission there. They are now installing a 500-volt Thomson-Houston generator of 62 k. w. capacity, for day use, with the special purpose of supplying power to machine shops, printing offices, elevators, and other miscellaneous work. The station is situated on the Cheboygan River at a distance of about half a mile from the center of the district to be supplied, with power, and the dynamos are driven by water power under a head of 11 feet. The Cheboygan River, which is tapped for this purpose, is fed by the chain of small lakes extending across the upper end of the lower peninsular of Michigan from Cheboygan to Petoskey. The large body of water thus furnished acts like a self-regulating reservoir, preventing the formation of freshets during rainy seasons and making the flow of water quite uniform and constant the year round. This new power circuit will be operated in conjunction with the regular electric lighting plant, from which the company are at present supplying the city of Cheboygan with arc lights for the streets, and houses, business places, etc., with both arcs and incandescents. The apparatus is Thomson-Houston. Charges for power will be made on the flat rate system, will depend on the kind of service required, and will be made low enough to be attractive to local power users. The officers of the company are: A. McArthur, president; C. E. Mould, secretary and treasurer, and W. F. DePay, vice-president.

TELEPHONY AND TELEGRAPHY.

THE NEW CABLE TO HAYTI.

THE submarine cable between New York City and Hayti was opened to the public at midnight, Dec. 1, for the transmission of messages to and from the West Indies. The cable approaches New York by way of Coney Island and Brooklyn. The main office of the company is at 1 Broad street, where the Commercial Cable Company has its office, and messages will also be accepted at all Postal Telegraph Company offices throughout the country. Interest attaches to the enterprise from the fact that the Attorney General of the United States applied recently for an injunction to prohibit the company completing its plans, alleging that it was a cloak for a foreign company. The United States and Hayti Telegraph and Cable Company replied, proving itself a bona fide



THE NEW YORK-HAYTI CABLE.

American company, and declaring that its object was to establish a competing service and to reduce rates.

The course of the new cable is shown in the accompanying map, the original of which has kindly been made for us by Vice-President George Clapperton, of the United States and Hayti Cable Company. The various connections are indicated. It will be noted that Hayti still has to reach Jamaica by way of Cuba. The new cable is about 1,500 miles long and has a resistance of 5 ohms per knot. The rate from New York City to Mole St. Nicholas, is $1.50, or a reduction of 35 cents per word, and the same to Port au Prince, or a reduction of 60 cents. Venezuela is reached for $1.70 per word, or a reduction of 70 cents a word.

With regard to this matter, Attorney General Harmon in his report to Congress last week, said: "Knowing that Congress at its last session, had under consideration a bill to regulate the landing of foreign cables, and believing that the general sentiment favors the exclusion of companies which refuse like priv-

ileges to American companies, I deemed it my duty to direct a suit to be brought in the Southern District of New York to enjoin the consummation of the plan above mentioned. My chief design was to afford Congress an opportunity to act upon the matter before this cable should be laid. Application for a restraining order was filed, but on the showing which the Government was able to make in the brief time it had to procure evidence, the motion was denied. The case, however, is pending and will shortly be heard. I respectfully suggest for the consideration of Congress whether it would not be wise to give authority to some executive officer to grant or withhold consent to the entry of such foreign enterprises into this country on such terms and conditions as may be fixed by law. The existence of any executive authority over the subject at present is involved in doubt, and the court in which the suit was brought appeared to be somewhat doubtful as to judicial authority in the matter. The companies defendant to the suit are the Compagnie Francaise des Cables Telegraphiques, the United States and Hayti Telegraph and Cable Company, and the United States and Hayti Cable Company. Their lines, commencing in France, are intended to reach this country via South America and Hayti, in both of which and possibly also in France I am advised that they have privileges which are exclusve, at least as to American companies."

THE TELEPHONE TRUNK LINE SYSTEM IN GREAT BRITAIN.—II.

(*Concluded.*)

BY J. GAVEY.

In designing the apparatus necessary for working the Department's trunk circuits in accordance with the foregoing principles, innumerable matters of detail had necessarily to be considered. Although switch sections of uniform size and pattern have been adopted, the requirements at the smaller offices are, of course, not exactly of the same character as at the larger ones; therefore three types have been provided, respectively known as "A, "B" and "C" sections. Small offices with less than three trunks are provided with an "A" section; offices with from three to 10 trunks are fitted with "B" sections; offices with more than 10 trunks with "C" sections.

These sections differ only in the minor details of the arrangement of junction circuits, the presence or absence of transfer circuits, referred to later on, and other small points. The principle of working is the same throughout, and, if the ultimate growth of the system at an office renders it desirable to substitute a "B" for an "A," or a "C" for a "B" section, the removal of the existing section is not necessary; but the conversion can be readily effected in situ by withdrawing certain movable ebonite slip holders fitted with one class of apparatus and substituting others.

As the result of the general experience of telephonic working in this country, and after careful consideration of the whole question, it was concluded that, as an average, a fairly skilled operator should work five trunk circuits with facility and without delay. Accordingly the unit section was designed to accommodate this number.

In ordinary methods of open-circuit trunk working the switch operator first inserts a peg in the trunk jack, then rings up her correspondent by means of a separate key or press button. The reverse operations are repeated at the close of the transactions, and if several trunks are connected at intermediate points these operations have to be repeated on each trunk.

With an automatic system of signaling the insertion of the peg indicates a call at the distant office, and its withdrawal indicates the close of the transaction. These signals are automatically repeated through any number of independent trunks which for the time being may be joined up to form one circuit. The conventional signals which have been adopted by the department are the following:

Indicator needle to the right.....	Line disengaged.
" " left......	Calling.
" " vertical........	Line engaged.

The line indicator is a combination of a polarized relay, the electromagnets of which are placed horizontally with an indicator needle in front of the poles. Normally, when the switch is fully manned, the traffic is regulated by the movements of the indicator needle alone, but for slack periods and at night the relay is brought into use to repeat calling signals through a local circuit by means of a bell or buzzer. These bells are cut out of circuit by suitable switches during the day. The manner in which the signals are transmitted is illustrated in Fig. 5.

It will be observed that in its idle position the line terminates on the indicator relay, in circuit with which is a battery of six cells, known as the "permanent current line battery." A second battery of three cells, known as a "permanent current local," is joined up through a 350-ohm resistance and through the right-hand half of the relay electromagnet in such a manner as under certain conditions to reverse the polarity established by the line battery.

The distant end of the line being terminated in a similar manner, the two positive poles of the respective line batteries are normally connected to the "A" line, and the two negative poles through relays to the "B" line. Thus, if the insulation is reasonably high, no current flows from either end, and these batteries have no effect on the relay indicators. On the other hand, the local permanent current batteries send currents

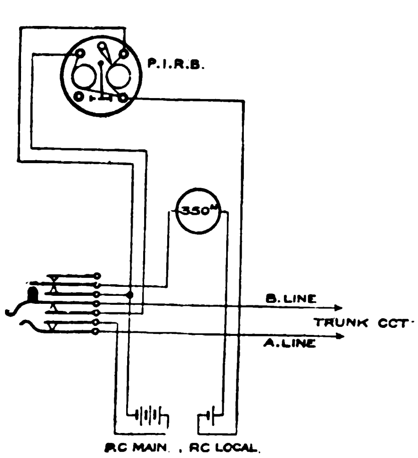


Fig. 5.

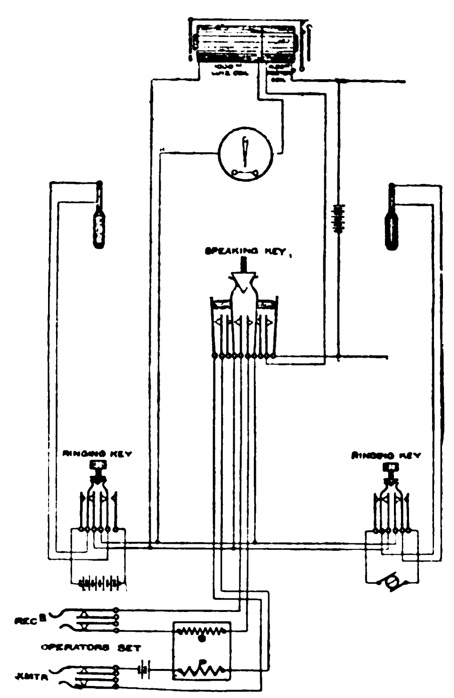

Fig. 6.

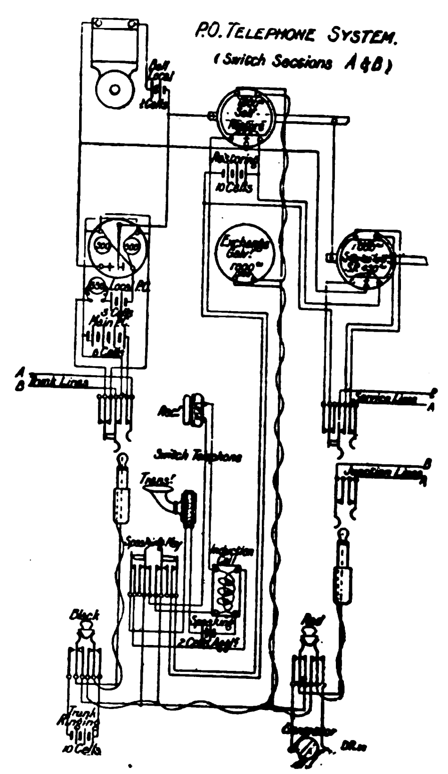

Fig. 7.

through the right-hand half of each relay electromagnet, the effect being to deflect each indicator needle to the right.

If the distant operator now inserts a peg, she disconnects her indicator relay with its opposing batteries, and substitutes the resistance of her local apparatus alone. The permanent current line battery current at the near end then flows with a reduced electromotive force due to the effect of the local battry, but in the opposite direction to the local current through the right-hand coil, and with the added electromotive force of the local battery through the left-hand coil of the relay. The polarity of the electromagnet is reversed, and the needle deflected to the left. On the insertion of a peg in the home jack to respond to the call, that indicator is also cut out of the line circuit, the local and line signalling batteries are disconnected, and the indicator needle becomes vertical.

Ringing keys are likewise provided; one set with black press buttons, being connected to batteries; the second set, with red press buttons, being joined to a small alternating dynamo, a pole changer, or a magneto ringer, according to the size of the office. The connections are illustrated in Fig. 6. The black keys are used for ringing up subscribers to postoffice exchanges, and for occasional use on the very long trunk circuits; the red keys for calling up the National Company's exchanges and subscribers.

Separate indicators are provided in the switch cords to announce the completion of the conversation, or the "ring off." There are two of these joined in series and bridged across each pair of cords, which form an electromagnetic shunt, with a resistance of 2,000 ohms. Owing to the self-induction of these shunts, they act as choking coils to the rapid vibrations of the

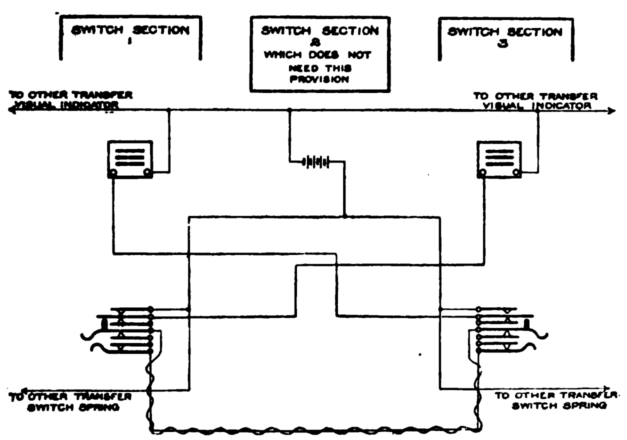

FIG. 8.

microphone, whilst responding readily to permanent currents or slow alternations. One of the indicators is a simple form of galvanometer designed to repeat the automatic signals in use on the department system, the second a Western Electric self-restoring indicator to respond to the magneto "ring off" of the company's subscribers.

When a postoffice subscriber is using a trunk circuit, on the completion of his conversation, the restoration of the telephones to their supports sends a permanent current to the exchange. This deflects the galvanometer needle described above; the exchange operators at both ends withdraw the pegs; and, if only one trunk circuit, is in use, the indicator relays, which are now brought into circuit, are both deflected to the right. If several minor trunks have been joined through at various intermediate points, the line permanent currents from the terminal offices deflect the needles of the telephone galvanometers at the intermediate points where connections have been effected. The operators, without further inquiry, withdraw the pegs, and the normal condition of things is restored.

When a trunk is in use by a subscriber to the National Telephone Company, the operators are dependent on the business-like aptitude, or otherwise, of the subscribers for the "ring-off." Should the latter fail to give the requisite turn of the handle to his magneto ringer the postoffice operators have to come into circuit at the expiration of the allotted period to inquire if the conversation is finished, before withdrawing the pegs.

Should a prompt reply not be given to an automatic call on a trunk circuit, the black keys can be brought into use to obtain attention.

Fig. 7 illustrates the connections on an "A" or "B" section.

Communication between different sections in one office to admit of joining one trunk circuit through to another can be effected in several ways. The most simple method of dealing with the problem consists in providing direct junction wires between each section and all the others; and this plan has been adopted where the sections are four or less in number, or where through trunking will, from the nature of the traffic, be infrequent. At large offices, however, the number of junctions necessary for this system would be very considerable; and, as in practice it would be necessary to limit this number, then each junction would have to be multiplied along all the sec-

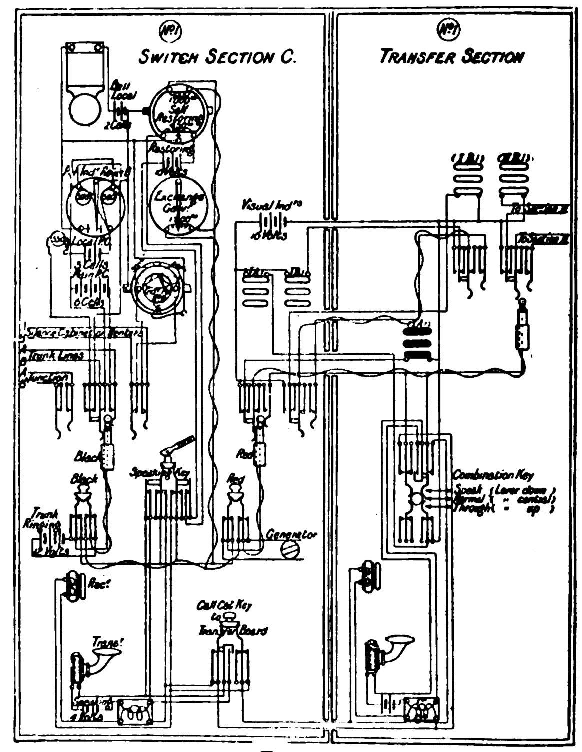

FIG. 9.

tions. To work these would involve the following operations:

First—Testing for the engaged signal.

Secondly—Ringing up the section wanted.

Thirdly—On receipt of reply, transmitting the demand; these operations in practice involving more or less delay.

To overcome these difficulties, the following modification of the divided board arrangement was introduced:

A through trunking or transfer section, sufficient to meet the requirements of 50 trunks, is provided for each 10 ordinary sections. From each section three "down" junction wires bearing the number of the section, and lettered A^1, A^2, A^3, are carried to the transfer section, where they terminate in cords and pegs. Similarly, two "up" junctions, terminated on jacks. numbered and lettered B^1, B^2, start from the transfer section to the respective switches where they terminate in jacks. The transfer switch is fitted with a three-key position for each "A" junction—

First position ....Normal
Second position ....Speaking
Third position ....Through

and both these and the jacks are provided with contacts which actuate small grid indicators, which have in practice received the somewhat inappropriate name of "visual indicators," through local circuits.

The connections for direct junctions connecting limited num-

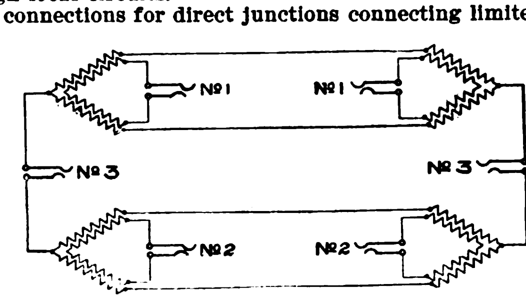

FIG. 10.

ber of sections in small offices are shown in Fig. 8, while Fig. 9 illustrates the transfer board working.

The system of duplex working that has been used by the National Telephone Company for some time has been adopted

by the department. Fig. 10 gives a diagrammatic sketch of the method of joining up. In this it will be observed that differential transformers are used, the secondaries being accurately balanced both for resistance and self-induction before they leave the workshop. No variable resistances are inserted, as any attempt to adjust in order to compensate for variations in the line would probably be a perfectly hopeless task. Under these conditions circuits of moderate length work satisfactorily, no ordinary changes in insulation resistance causing an upset of the duplex working so long as each of the arms is in sufficiently good order to work efficiently as a simple circuit. It is found, however, that if the circuits exceed a certain length it is difficult to maintain satisfactory duplex working; so that, for the present, this method is not applied to any exceeding 50 miles in length.

MISCELLANEOUS.

ELECTRICITY IN NAVAL LIFE.—XI.

BY LIEUT. B. A. FISKE, U. S. N.

POSITION FINDERS.

WHILE the appliances of modern warfare conspire to remove practical naval gunnery from the realms of chance to certainty, the art of coast defense is keeping pace, and is replying with every kind of thinkable device for increasing the rapidity and precision of fire of forts, i. e., for sinking attacking ships. Secured on firm emplacements, behind impenetrable walls, the guns and mortars of modern fortresses present the highest example of the combination of tremendous strength with refined precision. For the large calibers, the use of disappearing guns is on the increase, the gun disappearing behind the parapet after firing, to get a new charge. In order that the gun may be exposed above the parapet as short a time as possible, it is elevated on its carriage in accordance with the range signaled, and is trained in azimuth, according to the direction signaled before it is raised to fire, so that as soon as it is raised it can be immediately fired, and then by the energy of the recoil forced back at once to the loading position. Now, the determining of this range and direction is the office of a position finder. The simplest kind is the "depression position finder." Of this type there are a very great number of instruments in use in Europe, the most successful being that of Colonel Watkin, of which the English Government keeps the details a secret. In this country, that of Lieut. I. N. Lewis, United States Artillery, has proved extremely successful. It is not electric, however, and so a description would hardly belong here. The writer has endeavored to accomplish both the work of measuring and of signaling the results in instruments of this class by means similar to those employed in the range finder, in the manner hereinafter shown.

It may be pointed out here that if the position finder simply finds the distance and direction of the target from the position finder at a given instant, the people at the guns will not be benefited much, for two reasons: first, by the time that the gun can be gotten ready in accordance with any range and direction signaled, the range and direction will have changed; second, the people at the guns want to know the distance and direction of the target from their guns and not from the position finder. To remedy the first difficulty the people at the position finder do not signal to the guns what the range and direction are at that instant, but they predict what they will be thirty seconds later, so that the gun people have thirty seconds in which to lay the gun. To enable the position finder people to predict they take observations every twenty seconds, plot the exact position of the target each time on the plotting table of the position finder, and connect the various points by a line, more or less broken. A little practice enables them to thus lay down on the chart the exact track a ship is making. If the track shows that the ship has gone a certain distance in a certain direction in a certain time, it is not hard to prolong the track line so as to show where she will be two minutes later; in other words, to "predict her position." It is this predicted position that is signaled to the guns. When the ship arrives at or sufficiently near the predicted position, the signal is sent to the guns to fire. Of course if during the interval the ship suddenly changes her course and speed greatly, she will not reach the predicted position at exactly the end of two minutes. But a heavy ship cannot alter her course and speed so much in two minutes as to throw out the predicted position much, as even a rough calculation will show, especially if she is in company with other ships in a channel; and even if she could, it would be simply necessary to hold the fire until a new position were determined, which would be a matter of a few seconds only. The manner of using the position finder can be best shown by an extract from the official report on one placed at Spezia, Italy:

"The disposition of the Fiske position finder renders it possible to make rapidly a series of observations upon a target in motion, and to solve the problem of how she is going; to determine the route, the radius of the circle of turning, the speed, etc. During the recent trial at Spezia, the base line of the position finder being 104 meters long, there was determined the velocity of a torpedo-boat, which was going at a speed of 8 knots, of 10 knots, of 12 knots, maintaining a distance from the position finder ranging from 2,000 meters to 5,000 meters. There was determined at regular intervals the different points of her track, and the resulting speed deduced varied from the speed obtained on board the vessel itself by only 3 per cent. In order to give an idea of the quickness with which it is possible to fix the ship's position, and after the observers have had a certain amount of practice, it is sufficient to cite the fact that while the torpedo boat was making a complete circle of 250 meters diameter at a speed of 10.5 knots, the average distance from the position finder being 1,500 meters, there were plotted 11 successive positions. In another trial, while the boat was making a circle of 350 meters diameter, at a distance of 2,500 meters from the position finder, at the same speed her position was plotted 17 times."

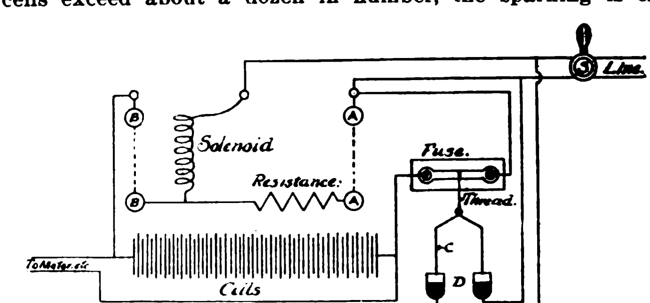
The position finder having determined the range and direction of the target from itself, it remains for the people at each gun to determine what are the range and direction from that gun. This may be done by means of tables of figures, which show for each gun what are the directions and ranges from that gun of every position that can be signaled from the position finder. But a speedier plan is offered by the instrument invented by Lieut. Rafferty, United States Artillery, called a "relocator," in which the conversion from one system of co-ordinates to the other is done mechanically. The instrument is extremely simple in construction, and (which is more important) is simple in operation, but not being electrical, its description hardly belongs here.

AUTOMATIC SWITCH FOR CHARGING ACCUMULATORS FROM AN ARC CIRCUIT.

BY EDGAR KIDWELL.

SINCE the first article under the above caption appeared in the November 11th issue of this journal, the writer has had an opportunity to subject the instrument to severer tests than were possible at first. These tests developed some defects and suggested improvements, which will now be described.

With only a few cells in circuit the design in Figs. 3 and 4 of the original article gives good results. But since the resistance is on the opposite side of the solenoid from that in the design given in Figs. 1 and 2, it follows that the potential difference causing the spark when the cells are thrown in, is that of the whole battery plus that necessary to drive the current through the resistance. In consequence, if the cells exceed about a dozen in number, the sparking is ex-



KIDWELL AUTOMATIC SWITCH FOR CHARGING ACCUMULATORS FROM ARC CIRCUITS.

cessive and the instrument cannot be considered satisfactory.

This defect is entirely obviated in the first design, here reproduced with certain additions. It is only necessary to make the resistance such that the fall of potential between its ends, when the arc current is passing through it, equals the potential difference between the terminals of the battery, where each cell is charged up to about 2.2 volts.

The writer now has 60 cells in series attached to an instrument adjusted in this manner, and the spark at A-A, when switching in the cells, is practically nil. When the number of cells is liable to vary from time to time, as in a laboratory, a variable resistance must be used for the best results. Graph-

ite resistances have not been satisfactory to the writer; hence he now uses metallic resistances entirely. The switch S should of course, be of the snap type, since a short circuiting switch, if thrown while the cells are charging, will short circuit the battery, since the automatic switch cannot act quickly enough to prevent the discharge current passing through the solenoid, thereby holding the beam down and keeping path B-B closed.

But there is always a possibility that an improper switch might be put in through mistake, or that the line wires might get crossed, or grounded, etc., and since one experience of this kind might ruin the cells, the following safety device has been used by the writer: A fuse, of capacity 50 per cent. in excess of the arc current, is put into the charging circuit, as shown. Should the cells be short-circuited by crossed wires or the switch S, etc., the automatic switch cannot act quickly enough to open B-B, but the fuse will blow out, and no harm can be done. But should the line current be turned on again before a new fuse is put in the automatic switch will act as usual, and since the charging circuit is broken, an arc will be established at A-A. To prevent this, two deep mercury cups are provided at D, and above them is a horseshoe shaped bridge piece, C, suspended from the fuse by a thread. When the fuse blows, the bridge falls, and the automatic switch, etc., is cut out, while the line circuit remains intact.

SOCIETY AND CLUB NOTES.

MEETING OF THE ELECTRICAL COMMITTEE OF THE UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION.

THE annual meeting of the Electrical Committee of the Underwriters' National Electric Association was held at the rooms of the National Board of Fire Underwriters, New York, on Dec. 7, 9 and 10, for the purpose of considering suggestions as to changes in the rules of the National Board for safe wiring.

There were present the following members of the committee: F. E. Cabot, Boston Board of Underwriters; C. M. Goddard, New England Insurance Exchange; Wm. A. Anderson, New York Board of Fire Underwriters; Alfred E. Braddell, Underwriters' Association of the Middle Department; E. A. Fitzgerald, Underwriters' Association of the State of New York; J. C. Forsyth, New York Board of Fire Underwriters; E. V. French, Associated Factory Mutual Insurance Companies; Wm. McDevitt, Philadelphia Fire Underwriters' Association; W. H. Merrill, Jr., Chicago Board of Underwriters; A. M. Shoen, South Eastern Tariff Association.

There were also present and acting with the committee, the following: Wm. T. Benallack, Michigan Inspection Bureau; Geo. W. Cleveland, Cleveland Board of Underwriters; James E. Cole, Boston Wire Department; J. Couilliard, New England Insurance Exchange; H. C. Cushing, Jr., New York Tariff Association; Herbert E. De Camp, Suburban Underwriters' Association; Robert C. Eden, Underwriters' Association of the Middle Department; Morton E. Eden, Underwriters' Association of the Middle Dept.; F. J. Fetter, Kansas City Board of Underwriters; Alexander Henderson, Fire Department of New York City; Frank Kitton, Buffalo Association of Fire Underwriters; George B. Lauder, New Hampshire Board of Underwriters; W. B. Lewis, Insurance Association of Providence; Wm. L. Puffer, Associated Factory Mutual Insurance Companies; Chas. R. Reynolds, Hartford Board of Underwriters; A. B. Smith, Canadian Fire Underwriters' Association; M. L. Stern, City Electrician, Denver, Colo.; R. Sweetland, New England Insurance Exchange; Geo. W. Wilson, Boston Fire Underwriters' Union.

Resolutions on the death of the late president of the association, Major C. E. Bliven, and Mr. G. F. Bottom, electrical inspector at Kansas City, Mo., were adopted.

The suggestions as to changes in rules which had been sent in on the blanks provided for the purpose, to the number of about 200, were then taken up in the order of the rules themselves, and after discussion, were acted upon; many of these suggestions emanated from the Committee on Code of the National Conference on Standard electrical rules. The changes made were not radical, being largely such as would improve or make clearer existing rules.

A number of standard tests for devices and apparatus, such as switches and cut-out blocks, were adopted.

Specifications and requirements for the use of plain iron pipe for conduit work were presented and ordered printed and submitted to the electricians present for criticism and suggestions.

In general it might be said that the nature of the suggestions offered and the changes made was such that the Underwriters' National Electric Association and its Electrical Committee may well congratulate themselves on their success in framing rules which having now been practically the only rules in use in the United States and Canada for three years, are found to need so few important changes from last year.

The secretary of the committee was also instructed in conjunction with some of the gentlemen present from Boston, to recodify the rules as amended, and submit the recodification to the committee for approval; this was believed to be important, as the various amendments made from time to time had to some extent rendered the present arrangement unsatisfactory, and it was thought that the general nature of the suggestions offered this year indicated that the rules were now so nearly perfected that this recodification was practicable.

A vote of thanks was extended to those who had interested themselves sufficiently in the rules recommended by the Association, to send in suggestions for their improvement, and especially to the Committee on Code of the National Conference on Standard Electrical Rules, for the several very pertinent suggestions offered by its members.

At the close of the meeting, the body went into committee of the whole, and voted to recommend the following elections to fill vacancies to the National Board, subject to the approval of the Executive Committee: H. C. Eddy, of Chicago, to be president; J. C. Forsyth, of New York, and E. V. French, of Boston, to fill vacancy in Electrical Committee; E. A. Fitzgerald, to be delegate to the National Convention on Standard Electrical Rules.

A code of rules and specifications for the installation of marine work, was reported by the special committee appointed last year, and ordered adopted with such changes as had been made necessary by amendments made at the present meeting.

"A STAR" PERFORMANCE BEFORE THE NEW YORK ELECTRICAL SOCIETY.

A CROWDED audience was drawn together by the subject announced for the meeting of the New York Electrical Society at Columbia College on Dec. 10, namely, the testing of a 1 horse-power dynamo and a 1 horse-power motor, in full sight of everybody. The novelty of the thing attested the ingenuity of Secretary Guy, and the merit of the performance can be gauged from the fact that it was presided over by Mr. Max Osterberg and was actually conducted by Prof. Crocker with his assistant, Mr. Sever, and Mr. C. O. Mailloux, with his assistant, Mr. Knox. These "stars" acquitted themselves brilliantly, Prof. Crocker describing what was being done and the other performers going through the successive acts and scenes with great ease and success. The motor and dynamo were mounted on the lecture room table, so arranged that they could be connected by a small brass sleeve and nut. The "drop method" was employed, and all the various readings were taken, and then the motor was submitted to a separate dynamometer test. The combination showed an efficiency of about 62 per cent. and the individual machines were therefore about 79 per cent. Additional to the descriptive talk by Prof. Crocker, and the tests, a number of lantern slides were shown illustrating forms of Prony brake and dynamometer and circuits for testing purposes; but the audience was very much of Prof. Crocker's opinion that while an electrical diagram is a deadly dull thing an electrical machine is an intensely interesting thing, and greatly preferred the tests. The motor and dynamo were kindly loaned by the Crocker-Wheeler Electric Company and instruments by the Weston Electrical Instrument Company. The dynamo delivered its current to a bank of lamps, but the pretty experiment was also carried out of turning its current back into the supply circuit.

PROGRAMME FOR THE NORTHWESTERN ELECTRICAL ASSOCIATION MEETING.

Mr. T. R. Mercein, secretary of the Northwestern Electrical Association, sends us the following programme laid out for the meeting to be held at Milwaukee on Jan. 20, and following days:

"Incandescent Lamps," by F. S. Terry, Chicago; "Protective Devices for Transformers," by H. C. Wirt, Schenectady, N. Y.; "Gaseous Fuel as a Means of Cheapening Electricity," by Nelson W. Perry, New York; "Transformers," by O. M. Ash, Elkhart, Ind.; "The Garfield Park Electrical Plant," by Forée Bain, Chicago; "Röntgen Ray Phenomena" (Illustrated), by Caryl D. Haskins, Boston; "Electrical Construction Affecting Insurance," by Geo. S. McLaren, Milwaukee; "Safety Devices for Electrical Circuits," by Prof. W. M. Stine, Chicago; "Electrical Supplies," by W. W. Low, Chicago.

ELECTRICAL WORKERS TO BE HOUSED IN.

The New York electrical contractors have decided that electrical workers will not be required to work during the winter in buildings which have not glass or sheeting to protect the workmen from the cold. The members of the Electrical Workers' Union say they will be able to do better and more work under this arrangement, as when their hands are numbed with cold it takes a day to do the work ordinarily done in several hours, and the work is not done so thoroughly.

The Electrical Workers' Union decided some time ago in favor of demanding an advance of wages from $3 to $4 a day, beginning with Jan. 1, 1897. They have now decided to notify the contractors that the demand will not be made until Jan. 1, 1898, in order that the contractors may be prepared for it.

ELECTRICAL TRADES ASSOCIATION.

The Association is doing quiet but excellent work in toning up local New York credits. At the annual meeting, held at the Astor House on Dec. 4, some 14 or 15 members were present and a permanent constitution was adopted. During the few months of work, about 150 cases have been disposed of—a remarkable record as to the economy and effectiveness of the work. It was decided to raise the initiation fee for new members to $50 after January 1, 1897. The Executive Committee consists of Messrs. Gallaher (chairman); Geddes, Thayer, Ackerman, Reed, Peck and Marshall. Similar work to that which has thus been done in New York and Philadelphia is now being done in Boston and Chicago.

LEGAL NOTES.

THE GOVERNMENT AND ITS TELEPHONE LITIGATION.

Attorney General Harmon in his annual report to Congress presented last week said:

"The suit by the Government to cancel the Berliner patent (United States vs. the American Bell Telephone Company and Emil Berliner), has recently been argued and submitted in the Supreme Court. The testimony for the Government in rebuttal, in United States vs. the Bell Telephone Company and Alexander Graham Bell, commonly called the 'Bell Telephone case,' pending in the District of Massachusetts, is almost concluded, but the sole counsel for the Government, Mr. Charles S. Whitman, of Washington, having died during the summer, I have not felt justified in employing other counsel for several reasons: First, the patents in controversy have long since expired; second, the only practical advantage which it is now possible for the Government to obtain will come from its winning the Berliner case above mentioned; if it lose that case, I see no sound reason for pursuing the other case further. Third, a very large sum has already been spent in the preparation and conduct of this case, some of the details of which were stated in the last report. The expenses of obtaining new counsel competent to finish preparing and to present the case would be very large, in view of the enormous mass of testimony already taken and the nature of the questions presented.

"In my judgment, this suit should be terminated on the best terms obtainable as to costs. I know of no reason why the Government, more than a private person, should waste money in litigation when its uselessness has become apparent.

"In view of there being now no special counsel for the Government in the case, I have made an arrangement with opposing counsel whereby no advantage will be taken of its present inaction. I again respectfully ask the direction of Congress as to the course to be followed in this case."

ACTION FOR THEFT OF CURRENT.

An unusual suit, growing out of the alleged tapping of electric wires, was heard by Magistrate Brownwell, at Reading, Pa., on Dec. 6. It was the prosecution brought against Tobacconist Samuel Hantsch and John C. Boone, who were charged with tapping the wires of the Metropolitan Electric Company used to illuminate the place of business of the former, so as to use the current to light up a show window, which did not register on the meter. C. C. Long, electrician of the company, who brought the suit, stated that some time ago it was noticed that Mr. Hantsch's bills were very small, considering the amount of light used; that he then made an inspection and found that the cluster of lights in the bulk window had been attached to the feed wire before it entered the meter, and that consequently the current used did not register. Mr. Hantsch claimed that he knew nothing about the matter, except that he thought the attachments were all right. The accused were held in $300 bail for court.

GERMAN RULING AS TO THEFT OF CURRENT.

A cable dispatch of Dec. 5 says:

A German court made an odd ruling this week in a remarkable case of larceny. A man was accused of stealing several thousand amperes of electricity by tapping a light company's wires and using it to run a dynamo (?). The court, on appeal, ruled that only a movable material object could be stolen, which electricity was not, and, therefore, the man was acquitted.

RESPONSIBILITY FOR A LIGHTNING ACCIDENT.

A rather novel suit has been instituted against the New York Telephone Company by the administrators of Lewis Edward Brown, of White Plains, who was killed by lightning in Unionville, in September last. With a party of friends Brown took shelter from the storm in a grocery. He was seated on a barrel in front of a telephone, which was attached to a post. He had jestingly remarked that he would call up the weather clerk, when there came a terrific peal of thunder and a blinding flash of lightning. Almost instantly a streak of fire issued from the telephone, and, striking Brown on the side of the neck, ran down his side to the floor. Several of the party were looking at Brown at the time, and they say they saw the lightning. The damages are placed at $20,000. Frederick W. Clark, of White Plains, is attorney for the administrators. The claim is based on the allegation that there was no ground wire attached to the telephone.

DOES A CENTRAL STATION "MANUFACTURE" CURRENT?

A case of general public interest is now before the Court of Appeals to Maryland from Frederick City, involving the exemption of manufacturing plants from municipal taxation. With a view to encourage manufacturing in the town of Frederick, an enabling act was passed by the Legislature and an ordinance was passed by the Board of Aldermen of Frederick exempting manufacturing plants from municipal taxation. Under this ordinance an electric light company claimed exemption from taxation. The tax collector of the town insisted upon the payment of taxes upon the theory that an electric light company is not a manufacturing corporation, at least in the sense contemplated by the ordinance. The case went into the Circuit Court. No other point than the one stated appears to have been raised in the pleadings, and the court decided, first, that the ordinance does not apply to an electric plant, and, second, that the enabling act was unconstitutional.

The question as to whether an electric light plant is a manufacturing plant has been treated as something of a scientific question. The contention has been made that electricity is already in existence. It is a free gift of nature and the manufacturing plant does not bring into existence anything that did not exist before. Upon this point the Court of Appeals of New York has said that electricity "is the product of capital and labor, and in this respect cannot be distinguished from ordinary manufacturing operations."

PROPRIETY OF EXHIBITS IN A TROLLEY ACCIDENT CASE.

Clara Rost, five years old, who was one of the victims of the Brooklyn trolley cars, secured judgment in the Supreme Court against the Brooklyn Heights Railroad Company for $27,500. On the trial, a physician on the witness stand exhibited the child's leg, which had been amputated, preserved in a bottle. The object was claimed to show by the physician's evidence that the electric current was still turned on when the child was run over. The Appellate Division, in Brooklyn, has just rendered a decision reversing the judgment.

Justice Hatch, who gives the opinion, after referring to the evidence as disclosing a case harrowing to the feelings in the extreme, says: "We have little difficulty, therefore, in seeing that upon the trial, where were developed all the details of so distressing a case, the emotions of the parents, and the pity excited for the little child, must have created an atmosphere tending to destroy the calm and dispassionate consideration of the real questions involved, and to prevent the jury from exercising that cool and deliberate judgment which should alone find place in a court of justice. * * * It is perfectly clear in the present case that the direct tendency of the exhibition of this mangled foot, coupled with the other considerations already noted, was to arouse the prejudice and inflame the passions of the jury to an angry resentment against the author of the misfortune." The Court holds that the verdict was excessive in amount, and that justice required the ordering of a new trial.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE.

EDITED BY MAX OSTERBERG, E. E.

Biographical:

HITTORF.—By Wm. Ostwald. On Oct. 26, '96, Wilhelm Hittorf celebrated the 50th anniversary of his graduation from the Berne University. The author thus found it appropriate to devote a few pages to a short biography of this old master and traces his principal achievements.—"Zeits. f. Elektroch.," Oct. 20, '96.

Central Stations:

LEYTON ELECTRIC LIGHTING WORKS.—An electric lighting plant where gas engines are employed which are fed from Dowson producer gas. The system at Leyton may be briefly set forth as low pressure three wire, 300 volts across the outer mains. In conjunction with it are a storage battery and motor generators. Each gas generator is designed to make gas equivalent to 100 British horse-power, and each has a cooler made of flat steel chambers, hydraulic box and coke scrubber, and sawdust scrubber. The gas holder is 20 feet in diameter, by 10 feet deep. Two small 3 horse-power vertical boilers are in the same compartment. The engines can be made to vary in speed from 160 to 200 revolutions per minute. Mr. Robinson, the consulting engineer, reports the following tests: The dynamos were run in parallel, and the current used to charge the batteries. Since the machines run slow for this purpose, the efficiency test on this occasion is unfavorable. The results of the tests which were carried on for 5 hours, are that 280 B. T. U. were generated, and the fuel consumed was 448 lbs. of anthracite and 52 lbs. of coke, giving 1.78 lbs. of fuel per unit. Taking the fuel at the full price, the cost per unit was less than .22d., which is very encouraging.—Lond. "Elec. Rev.," Nov. 20, '96.

ELECTRIC LIGHTING AT CROYDON.—This plant being of more interest in its details than in its general construction, consists essentially of the following: Three multitubular boilers, two feed pumps, a fuel economizer, three compound vertical condensing engines, each driving a 120 kilowatt alternator, and one or two dynamos with accumulators for the day load. There were to be three or four high-pressure feeders running to five transformer sub-stations in the center of the town, the power sent being 240 kilowatt at 2,000 volts. The water discharged from the condenser was weighed, with a result that at full load the consumption was found to be 17.9 lbs. per British horse-power. A plan of feeders and distributing network accompanies the article in Lond. "Elec. Rev.," Nov. 6, '96.

Dynamos and Motors:

ARMATURE REACTIONS.—By Alexander Rothert. Paper read before the Verb. Deutscher. Elektrotechn. After taking for a definition of armature reaction "the ratio between the exciting currents at no load and at some certain load, the e. m. f. being constant," the author discusses the effects in continuous and alternating current circuits. This paper having been previously referred to, it is interesting to note two letters attacking the author's method. These letters, one by Mr. Emil Giehl, of Berlin, the other by Dr. Robert Haass, appear in Lond. "Elec.," Nov. 6, '96.

BEHAVIOR OF NON-SYNCHRONOUS ALTERNATING CURRENT MOTORS WITH DIFFERENT CURVES.—By G. Roessler. The first of a series of articles in which the author briefly reviews the sine curve controversy carried on in the Lond. "Elec.," and the "Elec. World"; various types of dynamos were tested, the general result being that flat curves are preferable for motor service, except at very small loads.—"Elek. Zeits.," Nov. 12, '96.

Electro-Chemistry:

ELECTRICITY IN GOLD MINING.—Paper read before Eng's Club of Philadelphia, Oct. 17, by Dr. H. M. Chance. The writer describes the application of electricity to the extraction of gold from the ores. He points out six different methods, namely, electro-magnetic, electro-solvent, electro-amalgamating, electro-precipitating, electro-inductional and electro-smelting. Abstracted in Coll. Eng. and Met. Miner., Nov., '96.

Electric Railways:

SWITCH RUN BY ELECTRICITY.—This ingenious device consists of a double solenoid motor and a current reversing switch which is put in a small box under the switch tongue. The current is applied by means of the regular controller through an insulated section of the track near the track terminal. The device may be operated from the platform of the car. —"Elec. Jour.," Nov. 15, '96.

Electro Therapeutics:

ANTITOXIN BY ELECTROLYSIS.—M. Marmier, in a contribution to the "Annales de l'Institut Pasteur," refers to the work that has already been done on the question. He finds that continuous or alternating currents of low frequency destroy bacterial toxins. He thus disposes of the formation of antitoxin by electricity as at present recommended, for the fluid after electrolysis is perfectly different as regards its antiseptic power from the fluid before electrolysis is commenced. M. Marmier has thus disproved a pretty theory.—Lond. "Lancet," Oct. 24, '96.

Lighting:

METHODS OF CHARGING FOR ELECTRICITY.—A description of the Wright rebate indicator.—Lond. "Elec. Rev.," Nov. 6, '96. Also Am. papers of recent date.

Measurements:

ON A SATISFACTORY METHOD OF MEASURING ELECTROLYTIC CONDUCTIVITY BY MEANS OF CONTINUOUS CURRENT.—By W. Stroud and J. B. Henderson. Read before the Phys. Soc., Oct. 30, '96. Method consists in placing a balancing electrolytic cell in the arm of the Wheatstone's bridge adjacent to the arm containing the chief electrolytic cell, so that the e. m. f. of polarization in the two cells neutralize each other's effect on the galvanometer. Resistance of a solution can be determined with an accuracy of one part within two thousand. Abstracted with discussion in Lond. "Elec.," Nov. 6, '96.

METHOD FOR COMPENSATING FOR THE SELF-INDUCTION OF THE POTENTIAL COIL OF A WATTMETER.—By Ernst Danielson. Author tries to avoid the use of a condenser, for purely practical tests and arranges a set of coils, illustrated in the original article, by means of which approximate results may be quickly obtained. The total possible error, before any corrections are allowed for will be 34 per cent. For mathematical deduction see "Elek. Zeits.," Nov. 12, '96.

A NEW METHOD FOR DETERMINING POLARIZATION CAPACITY.—By C. M. Gordon. This method, based on a principle propounded by Nernst is said to be easily accomplished. Polarization capacity is compared with a condenser in an ordinary bridge arrangement. The telephone may be used in place of delicate instruments and alternating currents with known frequency are not essential. Details are given in "Zeits. f. Elektroch.," Oct. 20, '96.

Mechanical Engineering:

A REDUCING GEAR FOR ELECTRIC MOTORS.—An invention of J. MacEwan Ross, being a modification of double reduction spur gearing, which may also be used for gearing up speeds. The advantages claimed on ordinary spur gearing are: (1) driving and driven shafts are in the same line; (2) gear is compactly contained within an extension of the motor case; (3) high ratios of speed reduction are obtainable with gear wheels of comparatively small differences in diameter. An illustration of the gear appeared in Lond. "Elec.," Nov. 6, '96.

Power Transmission:

TESTS OF 150 KILOWATT PARSONS TURBO-ALTERNATOR.—Wm. D. Hunter made a set of tests showing extreme economy of steam. Consumption of steam was measured by calibrated tanks, from which the feed was drawn, and the electrical output was measured by a "Kelvin" wattmeter. The total water used per hour for about full, half and quarter load was respectively 3,484, 1.950 and 1,150 lbs., or expressed as pounds per electric horse-power per hour, the figures become 17.28, 20 and 22.01 respectively.—Lond. "Elec. Rev.," Nov. 13, '96.

Roentgen Rays:

X-RAYS.—By John Macintyre, M. B., C. M. Author, who is throat and nose specialist, discusses the different conditions of the tubes, then refers favorably to the use of the camera and in his observations on the fluorescent screen he remarks that a coarse, thick screen has given him favorable results.—Lond. "Lancet," Nov. 7, '96.

Telephony, Telegraphy, etc:

THE TELEPHONE TRUNK LINE SYSTEM IN GREAT BRITAIN.—By J. Gavey. Paper read before the Inst. of Elec. Engrs., Nov. 12, '96. A paper tracing the entire development of the system.—Lond. "Elec. Rev.," Nov. 13, '96, and subsequent issues. Elec. Engr., Dec. 9 and 16, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED DECEMBER 1, 1896.

Alarms and Signals:—

ELECTRIC SIGNAL BELL. C. E. Scribner, Chicago, Ill., 572,220. Filed May 31. 1894.
Adapted for police call or signal systems.

RAILWAY SIGNAL APPARATUS. B. B. Morgan, Ypsilanti, Mich., 572,268. Filed May 15, 1894.
A rail connection for both rails of a single track railway placed successively, and means whereby the operation of one by a passing train disconnects the other.

ANNUNCIATOR DROP. W. Schwageman, Yonkers, N. Y., 572,378. Filed May 31, 1894.
Employs two armatures to hold the drop in position when the former are influenced by a magnet.

Batteries, Primary:—

BATTERY CELL. C. Willms, Baltimore, Md., 572,285. Filed Aug. 15, 1896.
A battery cell or vessel having a seal or stopper of caoutchouc vulcanized to its prepared end.

CELL OR BOX FOR ELECTRIC BATTERIES. J. M. Moffat, London, Eng., 572,438. Filed May 23, 1896.
A box provided with an inwardly turned lip at its upper end, a sealing lid beneath the lip, and a vent arranged in the sealing lid and opening beneath the lip, thereby preventing the escape of liquid while permitting the escape of gas.

Batteries, Secondary:—

ACCUMULATOR OR SECONDARY BATTERY. F. W. Ellermann, Vienna, Austria-Hungary, 572,198. Filed Dec. 16, 1895.
A composition for manufacturing accumulator plates consisting of litharge and sulfate of magnesium mixed into a plastic mass with liquid ammonia.

BATTERY-GRID AND MACHINE FOR PRODUCING SAME. A. F. Madden, Newark, N. J., 572,363. Filed Nov. 19, 1895.
A battery grid having shelves or partitions and a suitable supporting frame formed of an integral piece of lead, the partitions being of uniform density throughout and of different density from the supporting frame.

Conductors, Conduits and Insulators;—

INSULATED ELECTRIC CONDUCTOR. W. R. Patterson, Chicago, Ill., 572, 215. Filed Dec. 10, 1894.
Comprises a conductor immediately surrounded by a layer of wool and a covering of cotton dipped in fireproofing compound.

Distribution:—

CURRENT CONTROLLING DEVICE. J. J. Hogan, New Haven, Conn., 572,507. Filed July 24, 1896.
Means whereby a current of high potential may be utilized for purposes where battery currents are generally employed.

METHOD OF AND APPARATUS FOR TRANSFORMING ALTERNATING ELECTRIC CURRENTS. M. Hutin and M. Leblanc, Paris, France, 572,510. Filed Nov. 4, 1892.
Consists in varying the coefficient of mutual induction of the circuits of a transformer in accordance with the law of variation of the alternating currents received or delivered by the transformer.

Dynamos and Motors:—

ELECTRIC LIGHTING MECHANISM FOR BICYCLES. F. E. Magee, Brooklyn, N. Y., 572,430. Filed March 25, 1896.
A generator is driven by the rear wheel.

Electro-Metallurgy:—

ANODE FOR ELECTROLYTIC PROCESSES. H. Y. Castner, London, Eng., 572,472. Filed July 26, 1895.
A carbon electrode composed of graphitized carbon of decreased density and increased conductivity as compared with a gas retort or like carbon from which it has been produced.

ELECTRIC FURNACE. E. F. Price, Newark, N. J., 572,312. Filed July 22, 1895.
Comprises a conducting hearth forming one electrode, a range of electrodes substantially perpendicular to the hearth, a supply hopper for the material to pass around the electrodes, and means for varying the inclination of the hearth and the movement of the material thereon as it passes from one electrode to another.

MAGNETIC SEPARATOR. J. B. Hamilton, Springfield, Mass., 572,162. Filed Dec. 5, 1893.
Intended for use in extracting particles of iron from pulp.

AMALGAMATOR. W. L. & C. Brown, San Francisco, Cal., 572,353. Filed Feb. 27, 1895.

MAGNETIC ORE SEPARATOR. C. J. Reed, Orange, N. J., 572,369. Filed Sept. 3, 1891.
Comprises magnets arranged inside of a hollow cylinder, and a second surrounding hollow cylinder through which the ore is advanced longitudinally in one direction, while the tailings are discharged in another direction.

MECHANISM FOR SEPARATING MAGNETIC FROM NON-MAGNETIC SUBSTANCES. C. J. Reed, Orange, N. J., 572,370. Filed Dec. 30, 1891.
Consists of a hollow revolving drum in combination with external magnets, an internal distributer and a hopper.

Lamps and Appurtenances:—

INSULATED JOINT FOR LIGHT FIXTURES. W. McElroy, Brooklyn, N. Y., 572,124. Filed July 26, 1892.
Especially designed for combined gas and electric light fixtures.

ELECTRIC LAMP POST. J. Buckner, Boston, Mass., 572,354. Filed Dec. 26, 1895.
Comprises a tubular metallic base-section and a double step composed of metallic strips clamped upon the wooden section, and the wooden strips clamped upon the metal strips.

REGULATOR FOR INCANDESCENT ELECTRIC LAMPS. W. Hawker, Montreal, Can., 572,421. Filed May 29, 1896.
Details of construction.

ELECTRIC LAMP. F. E. Magee, Brooklyn, N. Y., 572,431. Filed March 25, 1896.
Adapted for use on bicycles.

Measurement:—

VOLTMETER. A. A. Simonds, Dayton, Ohio, 572,380. Filed March 20, 1896.
Provided with a water jacket whereby the temperature of the coil is kept permanent.

Miscellaneous:

ELECTRIC SIGN. W. Connell, Pittsburg, Pa., 572,158. Filed March 10, 1896.
Means by which the position of letters or figures may be shifted at pleasure from a distant point.

ELECTRIC ROLLER FOR THERAPEUTICAL AND MASSAGE PURPOSES. J. W. Gibbs, New York, 572,431. Filed Sept. 22, 1896.

ELECTRIC TOWING APPARATUS. A. E. Schatz, New York, 572,377. Filed Jan. 19, 1893.
A motor adapted to run upon a track adjacent to a water way and means for connecting same to a boat whereby the latter may be towed.

ELECTRIC HEATER. B. E. Baker, New Britain, Conn., 572,467. Filed June 4, 1894.
Sad-iron.

ELECTRIC CLOCK. J. A. Schulte, Arcadia, Iowa, 572,131. Filed Aug. 12, 1895.
Comprises a primary clock, a generator, a series of electrically actuated clocks connected together by a single circuit, each having a setting circuit successively closed and each having a holding circuit, all such circuits being in series when current is traversing them.

ELECTRIC DOOR OPENING APPARATUS. O. H. Hicks and R. F. Troy, Chicago, Ill., 572,301. Filed Jan. 28, 1896.
Details of construction.

ELECTRIC STEAM AND GAS ENGINE. F. A. Rich, Telluride, Colo. Filed May 9, 1896.
A vessel having an inlet and outlet pipes and partially filled with a liquid, a steam generator supported by the liquid, a heating coil within the vessel, and electric conductor connecting the heating coil and steam generator with the source of electricity, and means for alternately opening and closing the electric circuit.

Railways and Appliances:—

COMBINED ELECTRIC AND GRAVITY PLEASURE RAILWAY. J. A. Griffiths, Philadelphia, Pa., 572,111. Filed April 7, 1896.
Employs electric motors on up grades.

ELECTRICALLY ACTUATED RAILWAY SWITCH. R. M. Hunter, Philadelphia, Pa., 572,169. Filed July 25, 1894.
Means whereby the motorman may throw the switch in advance of the car's approach.

Switches, Cut-Outs, Etc:—

ELECTRIC SWITCH. C. B. Sterling, New York, 572,319. Filed June 13, 1895.
Snap switch.

Telephones:—

EARPIECE FOR TELEPHONE RECEIVERS. D. C. Farrington, Washington, D. C., 572,108. Filed April 3, 1896.
Comprises an earpiece of a telephone receiver, a cushion detachably seated in the face thereof, and a detachable nipple communicating with the auditory passage through the earpiece and cushion and adapted to hold the cushion in its seat.

TELEPHONE TRANSMITTER. F. A. Ray, Boston, Mass., 572,182. Filed, Oct. 23, 1895.
A diaphragm is mounted between cushion rings of carbon.

TELEPHONE TRANSMITTER. L. D. Appleton, Waynesborough, Va., 572,188. Filed March 19, 1896.
Comprises a diaphragm, an electrode moving therewith, a second electrode fixed between the diaphragm and the first electrode, and a granular conducting mass interposed between the electrodes.

NEEDLE PLUG TEST SYSTEM FOR MULTIPLE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 572,218. Filed June 1, 1888.
Means for determining at one board whether a line called for is in use at another switchboard.

CORD SWITCH FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 572,219. Filed May 14, 1894.
Comprises a socket and a resting plug resting therein, a lever of the first class having one extremity bearing upon the side of the plug, switch-contacts actuated by the other extremity of the lever, and circuit connections with the switch-contacts.

TELEPHONE EXCHANGE SYSTEM. C. E. Scribner, Chicago, Ill., 572,221. Filed Oct. 16, 1894.
Means to prevent the connection of more than one line at a time with the operator's telephone.

TELEPHONE CIRCUIT. C. E. Scribner, Chicago, Ill., 572,222. Filed Aug. 1, 1895.
Comprises an inductive resistance in shunt to the telephone, and an electro-magnetic responsive instrument requiring for its operation a current greater than the maximum resistance of the transmitter would permit.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., and F. B. McBerty, Downer's Grove, Ill., 572,223. Filed June 6, 1894.
Comprises a connecting plug, an operator's telephone, an electromagnet connected with a circuit of the plug adapted to be closed during the insertion of the plug in a spring jack, and switching mechanism actuated by the magnet to interrupt the circuit of the telephone.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED NOV. 17, 1896.

Alarms and Signals:—

ELEVATOR SIGNAL APPARATUS. S. B. Opdyke, Jr., Philadelphia, Pa., 572,561. Filed April 24, 1894.
Means for signaling car to stop at landings.

ELEVATOR SIGNAL MECHANISM. S. B. Opdyke, Jr., Philadelphia, Pa., 572,562. Filed Oct. 8, 1894.
Similar to above.

ELEVATOR SIGNAL APPARATUS. S. B. Opdyke, Jr., 572,563. Filed Dec. 18, 1894.
Similar to above.

ELECTRIC SIGNAL APPARATUS. G. Knowles, Milwaukee, Wis., 572,607. Filed July 19, 1895.
Means to utilize the same electric circuit or generator for operating the signal transmitting mechanism as is employed for the transmission of signals.

Electro-Chemistry:—

PROCESS OF MANUFACTURING PHOSPHATES OF ALKALIES. H. Albert, Biebrich, Germany, 572,512. Filed Jan. 28, 1896.
Consists in forming bath of phosphoric acid and a bath of the soluble salts of the alkali metals, associating the two baths together in an electrical circuit, the baths being separated by a porous diaphragm and thereupon electrolysing the combined baths by passing a current of electricity through them, whereby a mono, di or tribasic phosphate of alkali employed is produced at the cathode.

Electric Furnaces and Heating:—

ELECTRIC FURNACE. J. E. Hewes, Philadelphia, Pa., 572,636. Filed Sept. 8, 1896.
Designed for the manufacture of calcium carbide.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. C. Goodyear, Jr., New York, 572,539. Filed Oct. 16, 1895.
Hand feed arc lamp for either alternating or direct currents.
ELECTRIC ARC LAMP. T. Spencer and C. Toerring, Jr., Philadelphia, Pa., 572,777. Filed May 6, 1896.
Feed mechanism.
ELECTRIC LAMP. L. A. Jackson, New York, 572,805. Filed July 25, 1896.
Bicycle lamp.

Miscellaneous:—

ELECTRIC ELEVATOR. John P. Casey, Bloomsburg, Pa., 572,525. Filed Aug. 23, 1894.
Details of construction.

Railways and Appliances:—

RAIL BOND. I. B. Walker and L. G. Nilson, Sioux City, Ia., 572,668. Filed Sept. 9, 1896.
Consists of a wire or strip of metal having terminal lugs, with a V-shaped portion cut away.
ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 572,706. Filed Nov. 4, 1896.
The strength of the field magnets is controlled by a gravity-influenced bar, so as to maintain the speed constant.
TROLLEY FOR ELECTRIC RAILWAYS. H. A. Seymour, Washington, D. C., 572,933. Filed June 15, 1896.
Consists of an elongated support attached to the upper end of the pole, and a trolley wheel adapted to travel laterally on the support.
SUPPORT FOR TROLLEY WHEELS. C. F. L. Orth, New York, 572,940. Filed April 16, 1896.
Device for keeping the trolley wheel upon the conductor wire.
ELECTRIC SWITCH. Charles H. Haberer, Louisville, Ky., 572,929. Filed Feb. 27, 1896.
Designed to be operated by an approaching car.

Regulation:—

SYSTEM OF AUTOMATIC ELECTRIC REGULATION. W. L. Bliss, New York, 572,627. Filed May 6, 1896.
Employs storage batteries to maintain a constant potential.
REGULATING ELECTRIC MOTORS. H. W. Leonard, New York, 572,903. Filed June 24, 1892.
A source of supply for the motor, and a regulating device in series with the armature of the motor and acting sometimes to return energy to the line.

Switches, Cut-Outs, Etc.

ELECTRIC SWITCHBOARD. E. A. Fordyce, Chicago, Ill., 572,748. Filed Nov. 4, 1893.
Comprises a switchboard having a plurality of keys, each provided with a contact piece, a controlling magnet having a connector common to the series and a plurality of electrical circuits corresponding to the several keys, each including its respective key and the controlling magnet and a circuit controller for each branch circuit.
AUTOMATIC CIRCUIT CLOSING DEVICE FOR GALVANIC BATTERIES. J. D. Holmes and W. L. Heath, St. Louis, Mo., 572,754. Filed Oct. 1, 1896.
Comprises circuit closing devices actuated by the rise and fall of the fluid of the cells for closing a metallic circuit through any cell when the fluid in it has fallen to a predetermined level.
AUTOMATIC CIRCUIT CLOSER. E. C. Williams, Clarksville, Tenn., 572,923. Filed May 9, 1896.
Adapted for telegraph and other closed circuit work.

Telegraphs:—

TELEGRAPH SYSTEM. B. F. Merritt, Orange, N. J., and J. M. Joy, New York, 572,609. Filed June 27, 1896.
Means to operate the line of a "Printing telegraph" system by one battery.
TELEGRAPHY. I. Kitsee, Philadelphia, Pa., 572,639. Filed Feb. 20, 1896.
Duplex system of telegraphy with alternating impulses.
PRINTING TELEGRAPH. L. Kamm, London, England, 572,760. Filed Dec. 30, 1895.
Apparatus to act as transmitter and receiver.

Telephones:—

TELEPHONE TRANSMITTER. R. L. Hunter and H. B. Higgins, Minneapolis, Minn., 572,756. Filed May 23, 1896.
Comprises a fixed base, line terminals, transmitter and interlocking means for securing the transmitter to the base and electrically connecting it with the terminals.
TELEPHONIC APPARATUS. C. J. Schwarze, Adrian, Mich., 572,775. Filed June 30, 1896.
An instrument which may be used as a transmitter, receiver and for signal purposes.
TELEPHONE EXCHANGE. M. F. Hill, Cambridge, Mass., 272,801. Filed July 16, 1895.
The combination of an answering division, a distributing division, and line circuits, each connected to two plugs, one plug at each division.
TELEPHONE SYSTEM. A. F. Swan, Bayonne, N. J., 572,840. Filed July 11, 1895.
Means in connection with any ordinary telephone instruments whereby several parties or instruments may be arranged on a line and any desired instrument cut in to the circuit while the others are at the same time cut out.

GREEN & BAUER, of Hartford, Conn., have equipped the Hartford Hospital with a set of Röntgen ray apparatus, which has already been used to good effect.

REPORTS OF COMPANIES.

COMMERCIAL CABLE AND POSTAL TELEGRAPH COMBINATION.

An arrangement has been made whereby the control of the Postal Telegraph Cable Company is placed in perpetuity with the Commercial Cable Company. The directors of both companies had meetings last week and acted on the arrangement. There is to be an absorption of all the Postal stock by the Commercial Company. The Commercial Company is to give in exchange a debenture, or collateral trust, bond upon which 4 per cent. will be guaranteed.

The capital of the Postal Company is $15,000,000. The Commercial Company's capital is $10,000,000. Neither company has any bonds.

A meeting of the stockholders of both companies has been called for December 22 to ratify the action of the directors. The new arrangement will cause no change further than to bind the two companies still closer together and perpetuate their present co-operative system.

The Commercial Cable Company directors have declared the regular dividend of 1¾ per cent., and an extra dividend of 1 per cent., payable January 1. The transfer books will close December 26 and reopen January 2.

SPANISH-AMERICAN LIGHT AND POWER COMPANY DEFAULTS ON ITS INTEREST.

The Spanish-American Light and Power Company, whose office is at 113 Wall street and plant in Havana and Matanzas, Cuba, is having a hard time on account of the war in Cuba. It is a New York State corporation, incorporated in 1883, with a capital stock of $4,000,000, and represents a consolidation of five gas and electric light companies in Cuba. It had a monopoly of the gas and electric lighting in Havana and Matanzas and before the war broke out its gross earnings, it is said, reached about $1,000,000 a year. Since then these have been considerably reduced, and the company is behind on its interest payment to bondholders, but has been paying up as fast as it could get the money. It was disclosed yesterday in the appointment of a receiver for Benjamin Giberga, who had been secretary of the company for a while, but who had resigned on Dec. 1, that the company had defaulted on the interest due on Nov. 1. The trouble, it is said, is due to the unsettled condition of affairs in Cuba, and particularly to the fact that the city of Havana won't pay what it owes the company for light. The amount is said to be $300,000.

BUSINESS OF THE NEW ORLEANS TRACTION COMPANY.

Some not unreasonable anxiety has been aroused of late in the minds of holders of the New Orleans Traction Company securities because of the earnings statements of the company for several months past. They have frequently shown a marked decrease from the results of the corresponding period in 1895. The statement for October shows that no marked improvement has yet begun, though the percentage of operating cost, while higher than in October last year, is decidedly better than that for October, 1894.

Inquiry on the subject of the road's present business shows that in addition to the bad effects due to the recent industrial depression, the company has also lost business by reason of the unsatisfactory service rendered by the Louisiana Electric Light Company, which has supplied the New Orleans Company with the power to operate its car lines.

This hindrance will in future be avoided entirely, since the company has just concluded an arrangement with the Electric Light Company by which the former will take entire possession of that portion of the electric light plant which was used to furnish power, and, having put in a division wall, will have entire charge of its operation.

It was recently stated that C. D. Wyman, who has been successful in charge of the traction system of Milwaukee, Wis., had been asked to take charge of the New Orleans system. It is now announced that he has signified his acceptance of the position, and will assume control next month.

WESTINGHOUSE DIVIDEND.

The Westinghouse Electric and Manufacturing Company has declared the regular quarterly dividend of 1¾ per cent. on the preferred stock, payable Jan. 1. At the meeting of the directors changes were made in the organization of the company. The offices of the general manager and assistant general manager were abolished and Lemuel Bannister was appointed first vice-president in charge of the commercial; B. H. Warren, sec-

ond vice-president in charge of the manufacturing, and P. F. Kobbe, third vice-president in charge of the financial department.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE BRODIE SINGLE POLE COMBINED SWITCH AND FUSE BOX FOR HIGH TENSION CIRCUITS.

WHEN double pole, out-door fuse boxes are employed on high-tension, alternating circuits the danger always exists of a short circuit being formed between the mains, with its consequent destructive action. It is for the purpose of obviating this constant menace that the Brodie Electric Company, of

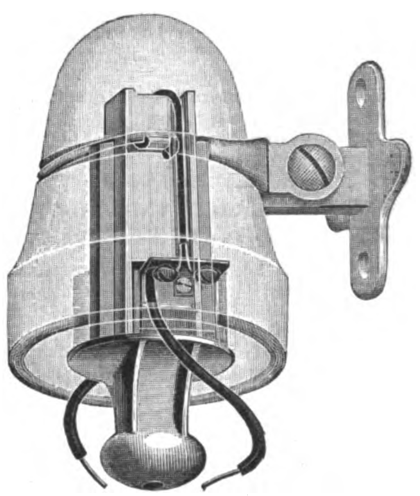


Fig. 1.—The Brodie Single Pole High Tension Combined Fuse and Switch.

Manchester, N. H., have designed a single pole combined switch and cut-out box for outside use on high-tension circuits. The illustration, Fig. 1, shows the device, which is made entirely of highly vitrified porcelain. In the engraving the

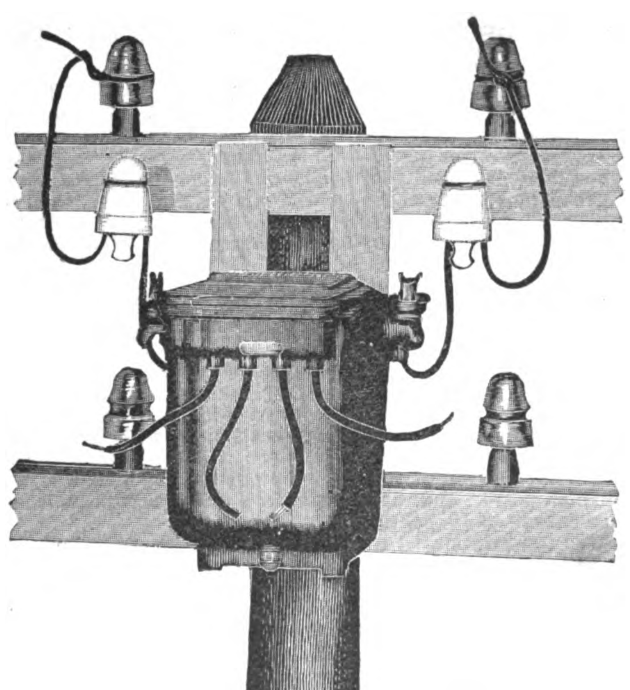

Fig. 2.—Brodie Combined Switch and Fuse, Mounted on Pole.

outer insulator is shown transparent, so as to clearly illustrate the construction of the plug.

The arrangement consists of an outside portion in the form of an ordinary insulator into a cavity in which a removable porcelain plug fits snugly, making the necessary connections. The fuse is carried in a groove in this plug, and as the plugs are interchangeable and very easily fused, the arrangement is a very convenient one. The circuit is opened when desired by the construction of the plug.

The construction is such that the arc formed upon the blowing of the fuse is instantly and certainly suppressed, and as the box is single-pole there is no possibility of a short circuit between the mains.

The petticoat of the insulator protects the electrical contacts from moisture, thus making it suitable for use with very high tension currents. The box is attached to its support by means of a malleable iron cleat, as shown, and is adapted for use on cross-arms, Fig. 2, or upon buildings, the cleat being screwed in place first and the box then attached. The contacts which hold the circuit wires are ample and easily accessible, and the arrangement is entirely weather proof.

The Brodie Electric Company are also manufacturers of the well-known "Brodie" automatic motor-switch, a perfect protection for electric motors against burn-outs and other accidents; and the popular line of "Brodie" insulators for tree and house use.

NEW GENERAL ELECTRIC MARINE ARC.

The General Electric Company's long-burning arc lamp has been adapted for ship use, both for the hold and on the deck. The "Marine" arc lamp is somewhat shorter than the standard long-burning arc lamp which has met with great success since its perfection, and is constructed to burn fifty hours without changing the carbons. The economy in carbons the use of this

Long Burning Arc Lamp for Marine Use.

lamp induces is considerable and this is added to in the saving effected in the labor of the trimmer. The outer globe of the Marine lamp is of clear glass and is cylindrical in shape instead of spherical. It is protected by a heavy wire guard against injury from outside. A large number of these lamps is already in use, both on the Atlantic and Pacific seaboards as well as on the Lakes.

THE EASTERN ELECTRIC COMPANY has been formed at New Haven, Conn., with a capital stock of $2,500.

NEW PORTABLE CABLE TESTING SET.

MESSRS. Elmer G. Willyoung & Co., of Philadelphia, have recently brought out a very compact and portable form of testing set for making measurements of the insulation resistance of underground and other high grade cables.

As shown by the accompanying engraving, the set is made up of galvanometer, telescope and scale, high resistance of 100,000 ohms, shunts, keys, and terminals for attaching the ends of cables being tested, the method of measurement being the usual one of direct deflections. The galvanometer is swung on gimbals and is adjustable about two axes passing through its center; the one perpendicular to its plane, the other lying in its plane. The adjustments are controlled by milled head screws.

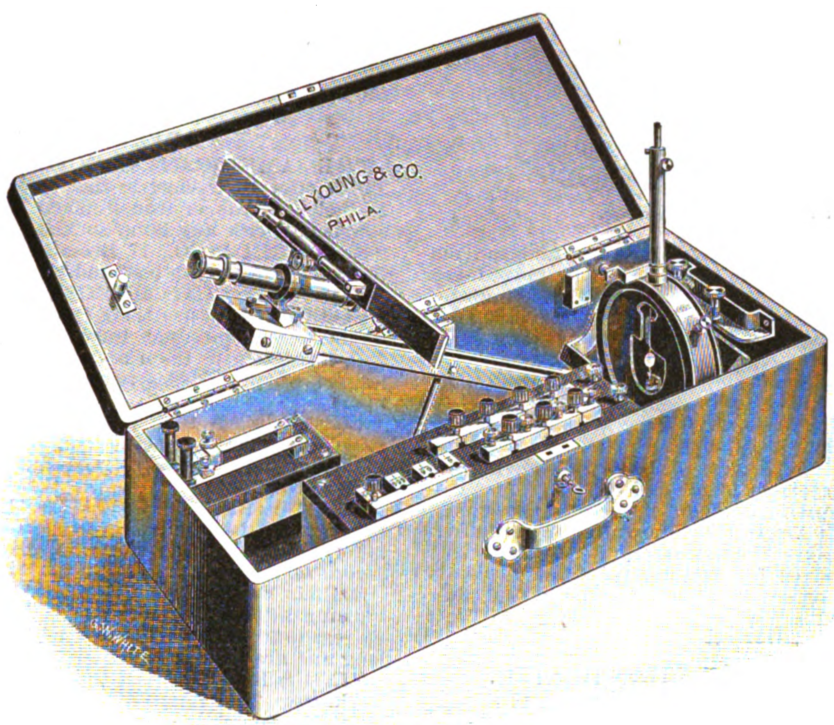
The telescope and scale are attached to the extremity of an arm which pivots around an axis lying in the plane of the galvanometer and passing through the center of the mirror; this arm rests flat in the bottom of the case when not in use, while the scale slips out of a kind of bayonet catch attached to the telescope casting and is held in a pair of holders seen at the side of the box. In consequence of the passing of this axis through the mirror center, the altitude and azimuth adjustments of the telescope relative to the supporting arm may thus be made once for all; the image of the scale must always reappear in the telescope by merely raising or lowering the supporting arm so as to secure the original angle with the galvanometer front. This supportng arm is held in position by a brass stem pivoted loosely upon it near the telescope and having an edge below which rests, ratchet-wise, upon a toothed rack. Hence when opening up the instrument for use it is merely necessary to adjust the galvanometer by means of the milled heads (regardless of the general level of the case which may rest upon a box, back of a wagon, on the ground), and then raise the supporting arm until the scale appears in the field, the arm remaining in any position to which it is raised. The entire time required to adjust the instrument in readiness to make measurement from its closed condition is about two minutes.

The shunts of this instrument are four in number, reducing the current passing through the galvanometer to 1-10, 1-100, 1-1000 and 10,000 of its original value. These shunts are not placed directly across the galvanometer resistance, as is usual, but across the galvanometer resistance plus an extra 100,000 ohm coil, the virtual resistance of the galvanometer circuit thus becoming over 100,000 ohms instead of only about 1,500 or 2,000 as would otherwise be the case. In this way the galvanometer resistance remains practically unchanged even though the moving coil should heat up a number of degrees under the sun's rays in field service—in case of the suspension breaking down and its replacement by a new one, there would be no sensible change in the galvanometer circuit.

This 100,000 ohm coil has another very important function to understand which attention must be directed to the well-known fact that the lead sheathing of a cable is itself a conductor for "return currents." These currents are constantly varying in value and location upon the cable, as the number of motors using power varies and changes in position. These variations of flow in the sheathing produce corresponding variable currents in the core of the cable. Hence when a steady current is sent from core through the insulation to ground, as it is in the direct deflection method of measurement, then variable currents superpose themselves upon the steady current and cause the motion of the galvanometer needle to be so erratic as to completely mask the steady deflection obtained. To overcome this difficulty the 100,000 ohm coil is wound with a maximum of self-induction, thus wiping out these variable currents, but offering no impedance to the steady current of measurement. This arrangement of inductive 100,000 ohm coil as also that of shunts outside of coil and galvanometer in series is the invention of Mr. W. D. Gharky, assistant superintendent lines and cables, Union Traction Company, Philadelphia.

All parts of the instrument possess the highest insulation, all metals and all conductors being mounted upon hard rubber, the galvanometer, coils, etc., being both moisture and dust proof.

With 100 volts this set is capable of measuring resistances up to something over 5,000 megohms, giving for this resistance about 10 scale divisions deflection.



WILLYOUNG PORTABLE CABLE TESTING SET.

As the galvanometer is of the d'Arsonval type, it is not affected by nearby electrical current or magnetic fields; neither is it affected appreciably by the ordinary mechanical shocks and jars of traffic. It is compact, measuring about 22¾x10x7¼ when closed, and weighs about the same as a dress suit case. The first of these instruments was made for the Union Traction Company of Philadelphia, about six months ago and has been in continuous daily use ever since and, we understand, is giving great satisfaction.

The set should be of great value to engineers and electricians in charge of underground construction, as it enables measurements to be made during progress of the work and any defects due to injury in "drawing in," etc., instantly located before the mischief has had time to develop and do perhaps irreparable damage.

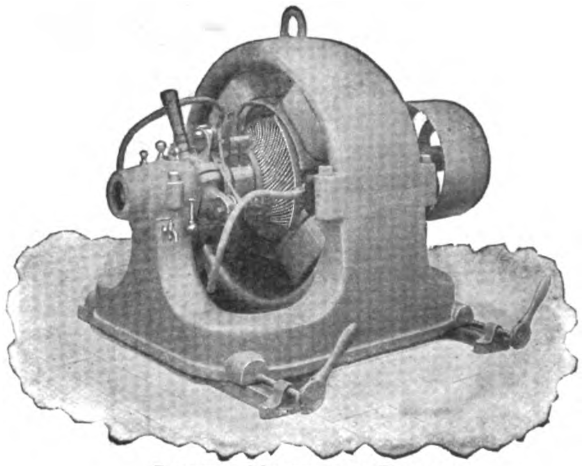
The apparatus is for sale by Mr. James G. Biddle, Drexel Building, Philadelphia, sole agent for Willyoung instruments.

MR. S. C. SCHENCK, for a number of years the New York expert for the C & C Electric Company, has resigned his position and has formed a connection as an associate with Mr. Thos. J. Fay. They are New York agents and exclusive exporters to Mexico, Central America, South America and the West Indies for the Crocker-Wheeler Electric Co.

THE NEW COLBURN FOUR-POLE GENERATORS.

THE Colburn Electric Manufacturing Co., of Fitchburg, Mass., have brought out a new series of multipolar generators designed to run at low speed, possessing a number of excellent features. The new generators, the general design of which is shown in the accompanying engraving, have laminated wrought iron cores, cast solid in the magnet frame, with compound wound magnet coils, which can be easily taken off. The design is such that the poles are short and influence the armature directly, thus giving the shortest magnetic circuit.

The armature is of the toothed type with the windings buried in slots and so constructed as to allow of the lowest possible resistance. The commutator is extra large, with tempered segments held in an improved and novel manner, and the machine is so well designed that the brushes can be moved over a large angle without causing sparking at the commutator. Another important feature consists in the fact that the commutators on these machines can be oiled freely without showing the least sparking.



COLBURN MULTIPOLAR DYNAMO.

The improved brush holders permit of giving the brushes any desired tension without stopping the machine, and they can be run continuously for months at a time without stopping, if required. This is made possible by the use of self-oiling boxes with double-ring oil feed, an oil sight showing the height of the oil in the reservoir at all times.

These machines are built for moderate and for slow speeds, belt driven, in sizes from 6¼ to 62½ kilowatts. The Colburn Company also manufacture the necessary accessories, such as automatic starting boxes for motors, potential rheostats, and also potential and current indicators for direct and alternating currents.

A NEW ELECTRIC CURLING IRON HEATER.

SINCE the universal introduction of electric lights in hotels, apartment houses and dwellings in our cities, to the entire exclusion of other illuminants, there has developed a demand for some method for heating irons for curling the hair. Alcohol lamps of innumerable forms have come rapidly into use, and have been a source of constant anxiety as well as no inconsiderable loss, due to fires resulting from accidents and careless use of these highly dangerous devices. Recognizing the demand for a safe and simple appliance, the American Electric Heating Corporation are introducing an improved electric curling iron heater so constructed that it cannot be in circuit unless the tongs are inserted in the heater. When they are removed, the circuit is automatically opened. The heater is made in nickel finish or polished brass mounted on polished marbleized base, complete with cord and plug for attaching to lamp socket. The current consumption is but 50 watts. For hotel use they are mounted on marble or other bases arranged to screw to the wall. Among other places, they have recently been installed as fixtures in the dressing rooms of the new Waldorf, and also the Majestic, in New York; also in seventy-five dressing rooms in the new addition to the Parker House, in Boston, besides which several additional large contracts have been secured. The illustration shows the general appearance of the device, which is a very attractive ornament, and provides an electrical Christmas present for the electrician's best girl.

NEW ELECTRIC CURLING IRON HEATER.

THE ELECTRIC APPLIANCE COMPANY.

The Electrical Appliance Company have just completed their fifth business year, and are congratulating themselves on the results. They began business five years ago, at their present location, occupying a part of the first floor of the building at 242 Madison street, Chicago. Their business has increased, demanding greater facilities from time to time, until now they occupy the entire building, and have a large basement, and the three large upper floors filled with valuable stock, and are one of the largest electrical supply houses in the United States.

Their supply line is very large and complete in every respect, and their line of specialties is perhaps the most desirable controlled by any one supply house in the country. Their facilities for transacting a large volume of business, to the satisfaction of the trade, and to their own profit is unsurpassed.

ADVERTISERS' HINTS.

THE AMERICAN ELECTRIC HEATING CORPORATION offer their electric foot-warmer at $7 (list). It is 9 by 10 inches, made of iron finished in black japan and may be connected with any lamp socket.

G. A. FREI & CO., 17 Bromfield street, Boston, claim their X-ray outfits are the best and cheapest.

THE IRON CLAD RHEOSTAT COMPANY, Westfield, N. J., notify and assure their customers that the apparatus they manufacture does not infringe any letters-patent owned or held adversely to them and further that they are prepared to protect all purchasers against any suit for alleged infringement.

THE CLIMAX GAS ENGINE COMPANY, 31 Fulton street, Brooklyn, are furnishing engines for high grade electrical work on guaranteed voltage fluctuation not to exceed one volt at full load.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., remind the public of their system of testing their engines before shipping and of sending each buyer a card giving the record of the test.

IDEAL ELECTRIC CORPORATION are advertising long-burning alternating arc lamps. They have no economy coil, no resistance, burn 100 hours with one trimming, are 30 inches long and are noiseless.

HINE & ROBERTSON COMPANY, 98 Cortlandt street, New York, say "the biggest kickers" are those who allow their plants to run down when by application of up-to-date appliances they can be made dividend payers.

ARMITAGE-HERSCHEL COMPANY, North Tonawanda, N. Y., build elevators to meet the most exacting conditions of speed, load and rise on direct alternating or phase circuits.

NEW YORK NOTES.

MR. MORTIMER NORDEN, of the firm of Miner & Co., New York, has applied for a receiver and dissolution of the partnership which previously existed between Edwin D. Miner, Edward F. Gavin and Mortimer Norden, composing the firm.

MR. CHAS. E. BROWN, who will be remembered as one of the pioneers in central station work, and was recently attached to the sales department of the C & C Electric Company, has resigned his position with that company with a view to taking up special work.

A CORRECTION.—In the advertisement of the Hine & Robertson Co., which appeared in The Electrical Engineer of Dec. 9, by an inadvertence the words "do not" were omitted from the fifth line of the first paragraph between the words "they" and "own." We have no doubt but that the average reader supplied the missing words in his own mind in reading the advertisement, but in order to avoid any confusion and uncertainty caused by their absence we call attention to the error and its correction.

Department News Items will be found in advertising pages.

THE

Electrical Engineer.

Vol. XXII. DECEMBER 23, 1896. No. 451.

Electric Lighting.

THE BRIDGE MILL POWER PLANT OF THE PAWTUCKET, R. I., ELECTRIC CO.

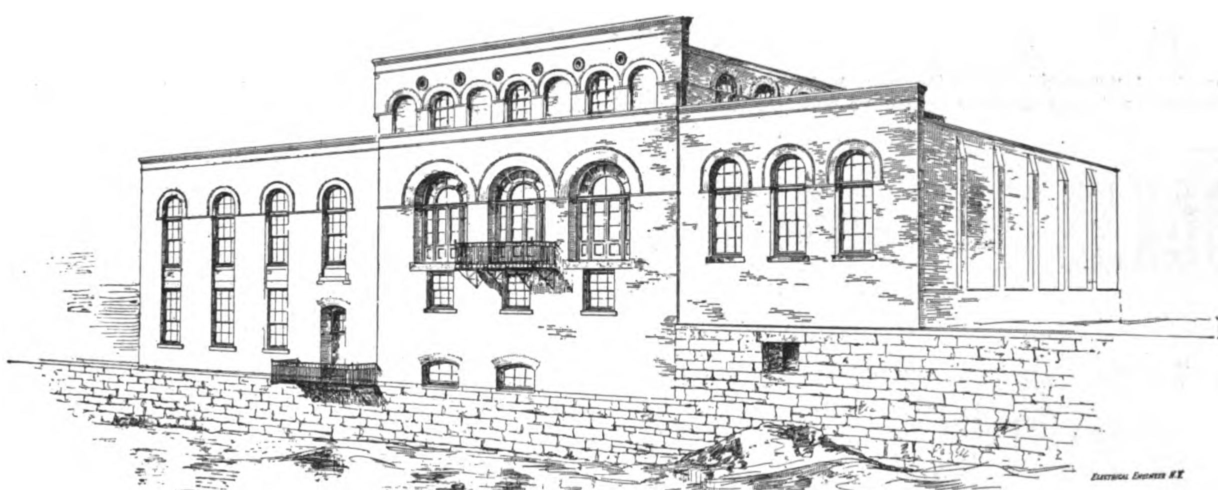
INTRODUCTORY.

THE Pawtucket Electric Company, of Pawtucket, R. I., incorporated May, 1896, is a consolidation of the Pawtucket Electric Lighting Company, owned by the Pawtucket Gas Company, and the Bridge Mill Power Company, owned by Messrs. D. L. and L. B. Goff. The first named plant was described in these columns when it was built some six years ago. It is sufficient to say now that it is a steam plant station fronting on the Blackstone river in Pawtucket about a mile below the Fall and conveniently situated for discharging coal direct to the boiler room. The buildings are all of brick with iron roof construction. The boiler room contains seven Bigelow horizontal tubular boilers; the engine room two Corliss engines of 650 horse-power each; and the dynamo room the usual arc and incandescent lighting apparatus. The station as a whole when it was built was an up-to-date one in every respect. Since the consolidation this station is now called the "Lower Station."

The "Upper Station," which is described below, is a water power station located right at the Falls in the very center of the city, with a 17-foot head of water and came into the possession of Messrs. D. L. and L. B. Goff in the following maner:

It was thirty-two years ago this fall, or in 1864, that the late Darius Goff and his son Darius L. Goff, began the manufacture of braids in the "Old Stone Mill" built on the East bank of the river in 1813. The business soon outgrew the narrow quarters and in 1872 the large brick Braid Mill was erected, and "Goff's Braid is the Best Made" became a household phrase. In 1874 the younger son, Lyman B. Goff, was admitted to the partnership. In 1883 the Old Stone Mill gave place to the larger and more modern brick structure now known as the Plush Mill. In 1884 the company was incorporated under the firm name of D. Goff & Sons. In 1885 Mr. Goff, Sr., then in his 76th year, and at an age when most men would have hesitated to assume new cares and responsibilities, made his first purchase in the property on the west side of the river by buying out the small interest of one of the numerous heirs. The records show that during that year he bought the interests of three heirs in the property. In 1887 he bought the interests of five heirs. In 1888 the interest of one heir, and in 1890 the interest of four heirs, having thus secured previous to his death in 1891 about one-half interest in the so-called "Pardon Jenks" estate, the "New Mill" and the "Grist Mill" estates.

In January, 1893, the remaining one-half interest, held by seven heirs, was bought by his sons and they thereby came into possession of the entire property, land and water power.



THE BRIDGE MILL POWER PLANT OF THE PAWTUCKET ELECTRIC CO.

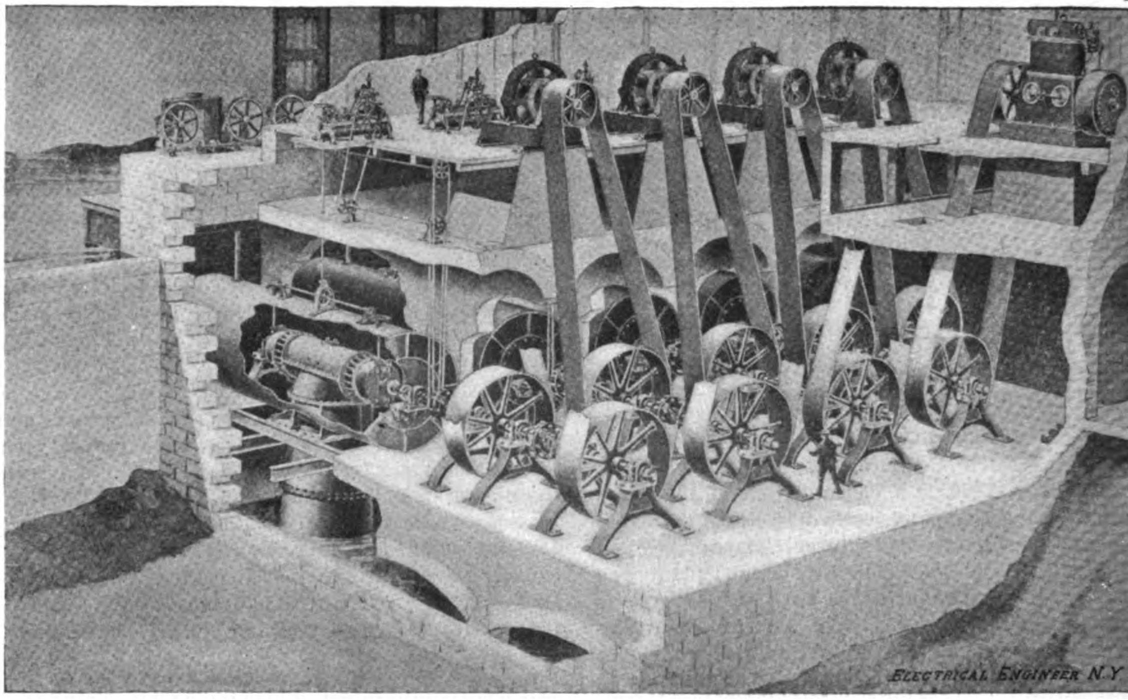
They immediately set to work to develop this water power, which for many years had been going to waste over the dam right in the very center of a thriving manufacturing city, to the wonder of every visiting stranger not acquainted with the peculiarity of ownership.

The original plan of development contemplated the opening of a new street 700 feet long through the property and the erecting of buildings on the same, the first floors to be for stores, the upper stories for light power for manufacturing purposes and larger buildings in the rear and on the river front for heavier manufacturing, all the power for the same to be supplied in the form of electric motors driven from the electrically equipped water power station.

THE HYDRAULIC AND MASONRY WORK.

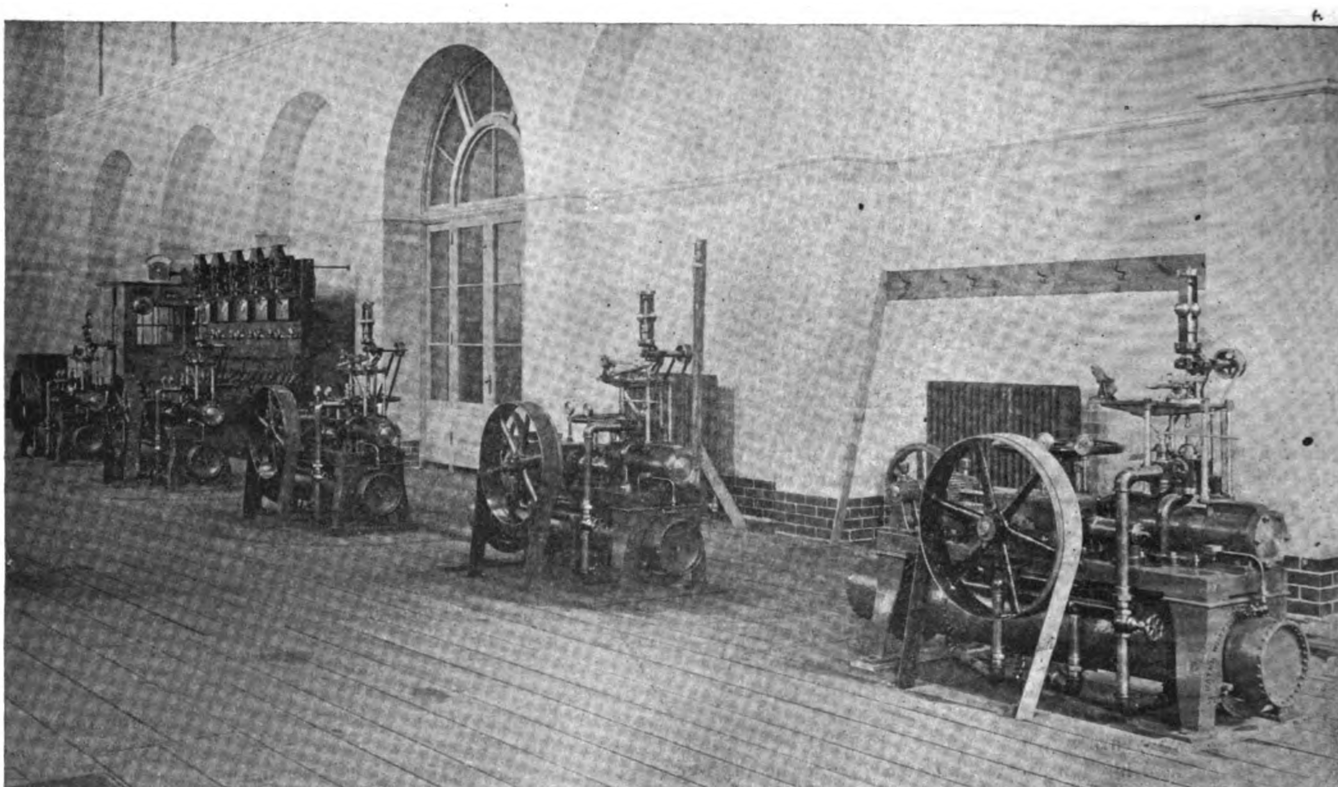
Messrs. Shedd & Sarle, of Providence, were selected as hydraulic engineers, with J. Herbert Shedd, C. E., as consulting engineer, and to them was entrusted the plan of masonry and brick construction, including brick dam, an underground

brick conduit 130 feet long and 17½ feet in diameter, forebay, penstocks, gate hoists, wheel pit, and wheel work. In July, 1894, a contract was made with Everson & Liddle, of Providence, to build a heavy granite retaining wall on the newly established harbor line and to do all the other masonry and brick work. All work exposed to water was laid in the best Portland cement and the construction is of an unusually substantial character. The superstructures, consisting of gate house, power house and boiler house, have since been completed and are all of brick with flat roofs of porous tile covered with asphalt and gravel, and were designed by Stone, Carpenter & Willson, architects, of Providence.



THE BRIDGE MILL POWER PLANT.—SECTIONAL PERSPECTIVE, SHOWING ARRANGEMENT OF TURBINES, ENGINES AND TRANSMISSION GEAR TO DYNAMOS.

(Copyright, 1896 by the Rodney-Hunt Machine Co.)



LOMBARD WATER WHEEL GOVERNORS IN BRIDGE MILL POWER PLANT, PAWTUCKET, R. I.

THE WATER WHEELS.

The water wheels and flumes for the Bridge Mill plant as also the power transmission equipment, were installed complete by the Rodney Hunt Machine Company, of Orange, Mass. There are five pairs of special 33" McCormick water wheels mounted on horizontal shafts in iron cases, and each flume is 10 feet in diameter and about 30 feet long. The aggregate power furnished by the wheels, with fall of 17 feet, is fully 1,300 horse-power.

The arrangement of the turbines and shafting are shown in the sectional perspective on page 638. The wheel shafts are 6 in. in diameter and are coupled direct to the extension shafts, with friction cut-off Worrall couplings, and another similar coupling is provided between the first extension shaft carrying a pulley 9 feet in diameter by 29 in. face and the second extension shaft carrying a similar pulley. One of these pulleys is belted direct with the dynamo on the floor above and the other is belted from the steam engine above, which is designed to run the machinery in dry or summer months when there is not sufficient water. This arrangement provides for driving dynamos with the water wheels or the steam engine, one independent of the other or using both together, disconnecting and connecting as desired without stopping the dynamo, and thus use the available water supply at all times to the best advantage.

The pulley shafts are suported by cast iron floor stands and pivot, self-aligning, self-oiling ring bearings, the elevation of the shaft center being 5 feet above the cement floor. The bottom of the stand covers a space on the floor laterally of 8 ft. 6 in. and is bolted to granite blocks embedded between steel beams set in the cement floor.

THE WATER WHEEL GOVERNORS.

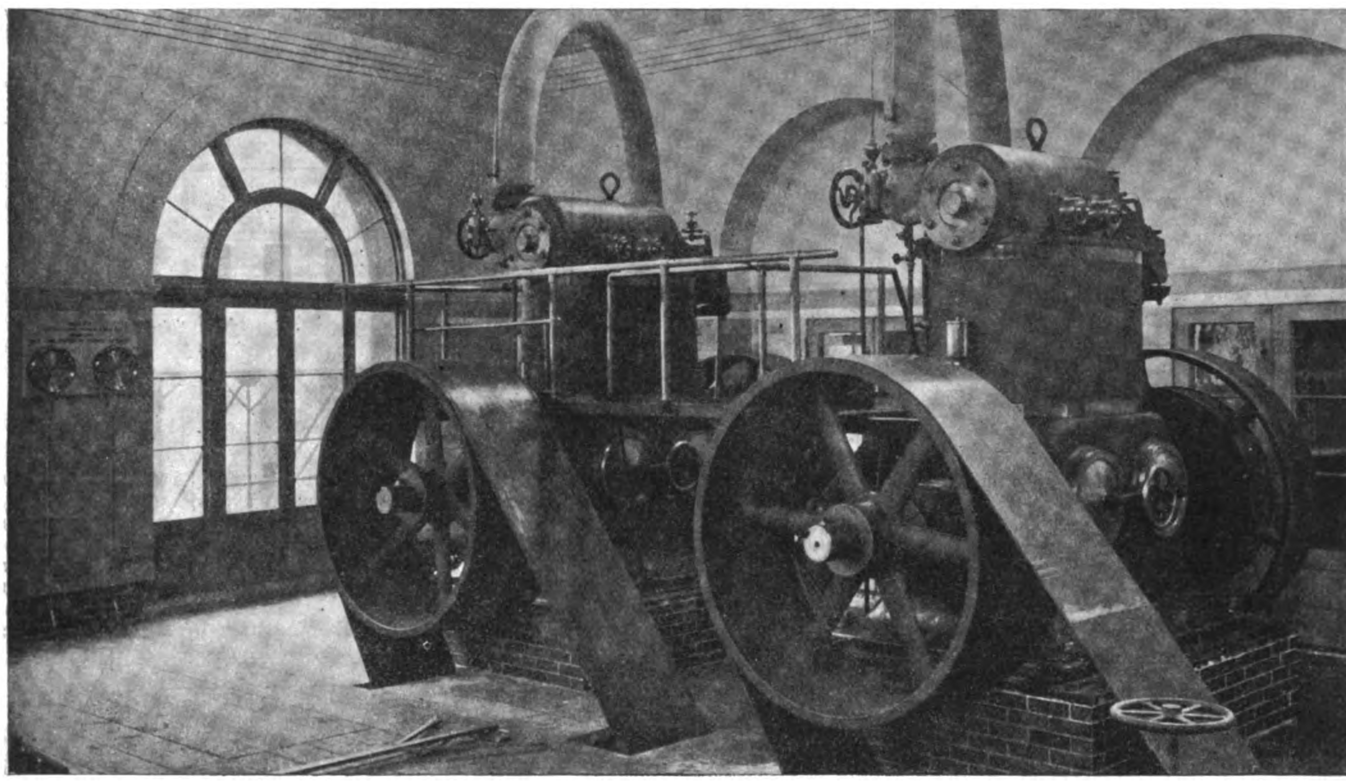
The five pair of water wheels above described are regulated by five standard Type C governors made by the Lombard Water Wheel Governor Company, Roxbury, Boston, Mass., and shown in perspective on page 638.

There are thus five units, each consisting of one pair of water wheels, one electrical generator and one governor. The system is perfectly flexible. The terminals of the electrical generators all go, through the switchboard, to one set of bus bars, and any one, or all, or any combination of the five units may be operated at will.

When more than one unit is in operation they have no positive connection through clutches, belting, or similar devices, but are electrically connected at the switchboard. Under these circumstances it was feared at first that there might be some difficulty in driving five pair of water wheels at near enough the same speed to avoid the ordinary difficulties of operating generators in parallel when driven by independent water wheels. It was found, however, that these fears were unfounded, and the gates of all the water wheels open and close exactly alike, so that they give the appearance of being in some way connected, though in fact all of the governors operate entirely independently.

As these governors start and stop the water wheels without manual effort on the part of the operator it is a simple matter to throw in or out of operation whichever, and as many, of the five units as the operator sees fit. Thus any water wheel may be started or stopped without touching a hand wheel, and in case of the entire load going off instantly, as frequently occurs through the opening of the circuit breakers, no attention is paid to the water wheels or governors, as they take care of themselves.

The load variations of this plant are such as are commonly found in electric railway stations and the governors easily hold the speed within three per cent. of normal, except in cases of circuit breakers opening, when variations of about five per cent., lasting about fifteen seconds, occur.



WESTINGHOUSE COMPOUND AUTOMATIC ENGINES IN BRIDGE MILL POWER CO.'S STATION, PAWTUCKET, R. I.

THE STEAM PLANT.

The steam plant connected with this station, which was installed by Messrs. Westinghouse, Church, Kerr & Company, is very complete so far as constructed, and although intended primarily as relay to water power, its use is sufficiently extensive and important to warrant the adoption of a number of advanced forms of construction and design. The illustrations on page 640 show the details of the engine and boiler arrangement.

The engines, of which there are two, are Westinghouse compound automatics, having cylinders 16" and 27" diameter and 16" stroke, and they run at a speed of 250 r. p. m. Their mechanical design and steam distribution make them especially adapted for the service and to produce the most economical results under the variable loads and conditions. Each engine delivers its power to one of the 150 kilowatt dynamos through jack shafts located in the wheel room below.

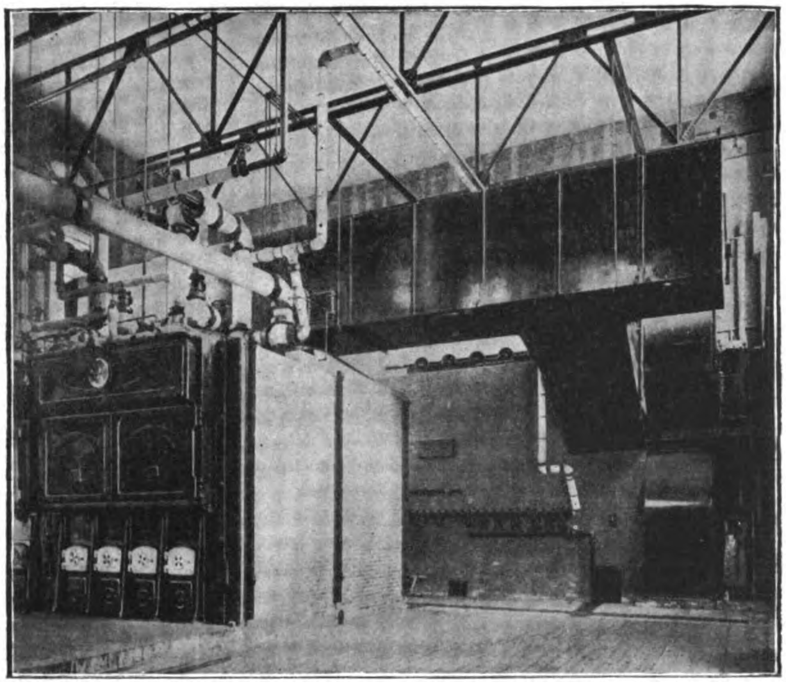
These jack shafts form an extension of the water wheel shafts, of which there are five located parallel to each other and to the engine shafts, and each is provided with two cut-off friction couplings operated from the engine room level.

The generators are belted from pulleys located between the two friction couplings and, as stated above, the arrangement

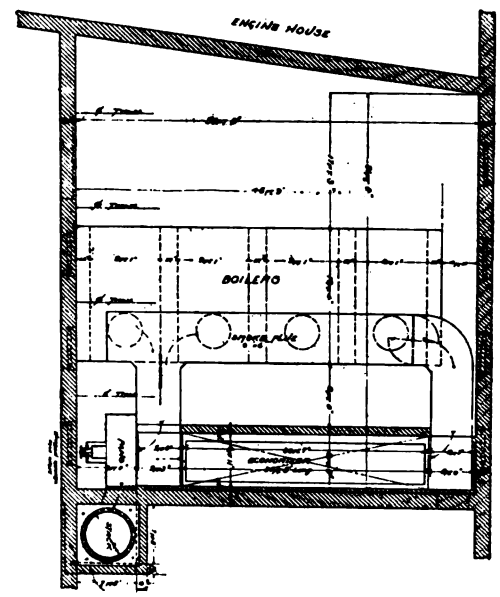
is such that they may be driven entirely by water, entirely by steam, or for that matter by both in conjunction should circumstances ever make it desirable to do so.

Each engine forms, therefore, with its companion wheel and generator, a complete unit, which can be independently adapted to the varying conditions of load, available water, etc., and always to the best advantage.

The engine receives steam through long bends of extra

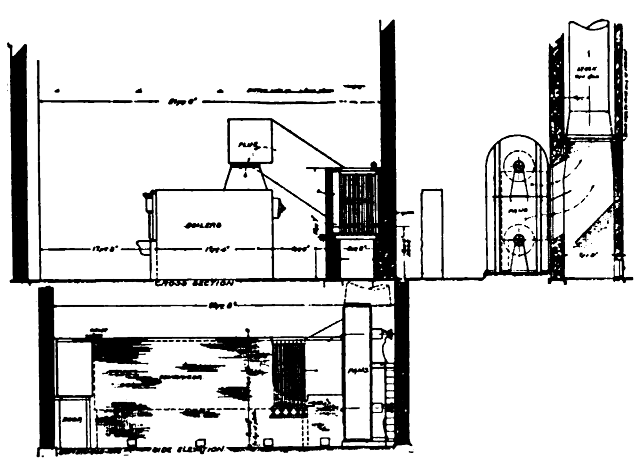


Bridge Mill Power Plant.—Boiler Room and Economizer.



Boiler and Economizer. Elevation.

heavy pipe rising from a header located in a high basement under engine room, and the exhaust is delivered to an exhaust system extending through the basement and into the boiler room where it is connected with a Deane independent condenser of suitable capacity to handle the exhaust of both engines. The general arrangement of steam and exhaust piping is shown on the accompanying engravings in plan and elevation, and is exceedingly well designed. A portion only of the ultimate plant has been installed, but the piping is constructed with special reference to the best arrange-



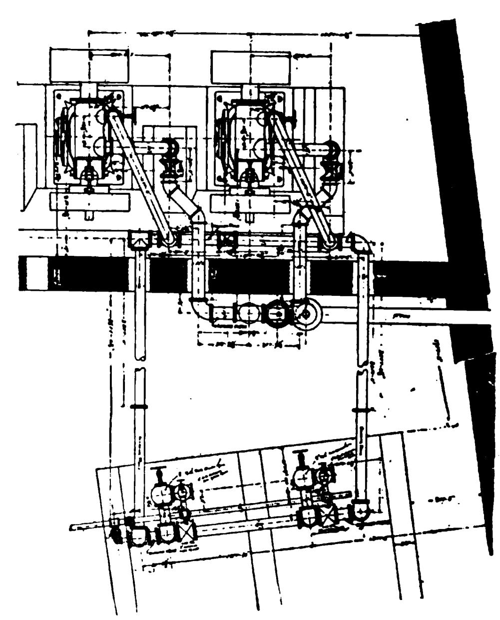
Bridge Mill Power Plant.—Boiler, Economizer and Fan. Elevation.

ment of the complete installation, and is planned for extension on the same general lines shown by the drawings. The plant is designed to run condensing, but may be run non-condensing at will. Provision has been made for changing to a non-condensing basis automatically in case of a loss of vacuum from any cause. All the fittings and valves in the live steam system are extra heavy and everything connected with the piping is of the very best. By the ingenious arrangement of the piping any portion may be cut out of service if desired for any reason without interfering with the general operation of the plant, and many of the advantages of dupli-

cate lines of piping are secured without their accompanying complication and cost.

Particular attention has been given to the matter of drainage for the live steam system, and this has been protected by a system of steam loops, the "horizontals" of which may be seen, in the view of the boiler room, hanging from the upper members of the roof trusses. These steam loops continuously gather up the water of condensation and entrainment that is present in the steam pipes and return it without moving mechanism to the boilers in a very satisfactory and economical manner. The feed piping is entirely of soft annealed brass tubing; all valves and fittings are also brass of heavy pattern and the connections between feed pump, heater, injector, economizer and boilers are cross-connected and by-passed.

The boilers are two in number and are of the Heine water



Bridge Mill Power Plant.—Plan of Engine Piping.

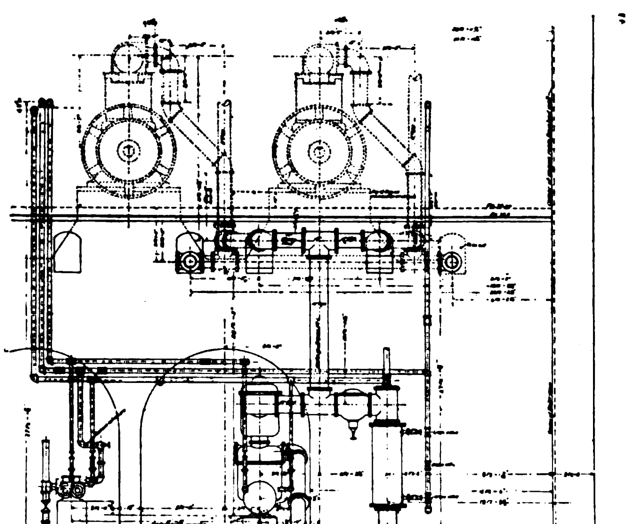
tube type. They are connected to a suplementary heating main not shown in the engravings, but which is intended for heating the braid mills of D. Goff & Son, located across the river. The products of combustion are carried by means of a suitable flue connection to an economizer and mechanical

draft plant, the principal features of which are shown in the illustrations.

This economizer and mechanical draft plant can also be seen clearly at the right and rear of the perspective view of their heat to the in-going feed water, which passes through the economizer where they give up a large portion of their heat to the in-going feed water, which passes through the economizer tubes. Beyond the economizer are placed two large slow speed fans arranged for exhausting the cooled gases from the economizer and providing draft for the fires. The economizer is of the improved circulating type designed by Westinghouse, Church, Kerr & Company. The circulating and blow-off connections are located outside of the economizer setting for ease in handling and cleaning and may be seen in the perspective view of the boiler room.

The fans are driven by direct connected engines, and are of the regular design of the contractors for this service. They meet the requirements imposed by the high temperatures of the gases handled most satisfactorily. They discharge into a short stack which extends only to a sufficient height to carry the products of combustion away from the building. A comprehensive system of relay has been arranged in connection with the economizers and fans so that either fan may be used to produce draft with or without the use of the economizer, thus absolutely insuring against stoppage of operation for repairs or otherwise.

The mechanical draft apparatus supplants the usual tall and expensive chimney and the economizer absorbs and saves a large amount of heat which would otherwise go to waste. Together they form a very complete and economical device for saving coal and making and controlling draft. When



BRIDGE MILL POWER PLANT.—STEAM PUMPS, CONDENSERS, PIPING. ELEVATION.

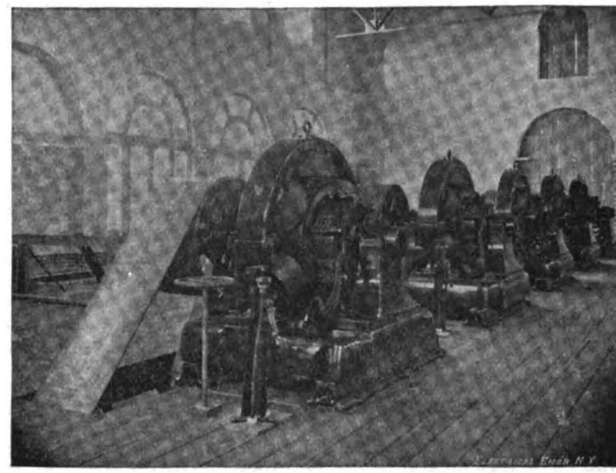
combined in this way the gases may be cooled to a temperature below that necessary for producing natural draft and a further gain in economy thereby made.

THE ELECTRIC EQUIPMENT.

The Bridge Mill Power Company have five of the latest type of General Electric 6-pole 150-kilowatt generators shown in prospective on this page, running at 400 revolutions. These generators are remarkably compact, and give an appearance of great strength and solidity. They have a cast steel magnet ring, and in general outline follow the lines of the General Electric standard 6-pole machines of the railway type. These machines have an overhung pulley, on which account the shaft is unusually large, being 5½ inches in diameter in the journal. The box next to the pulley is of extra length and size, by which means the strain due to the overhung pulley, is well distributed. The armature is of the ventilated "barrel" construction, which gives a firm, iron foundation under the entire length of the winding. The brush holders, of which there are six sets, are of the parallel spring type, with a positive path for the current, formed by a flexible copper cable attached to the holder at one end, and the other plugged into the top of the brush. Each generator is equipped with an equalizing switch attached to the separate stand near the machine.

The switchboard consists of one panel for each generator, equipped with a standard circuit breaker, ampere meter, and single pole quick break switches; one Weston illuminating dial voltmeter on a swinging arm answers for the entire switchboard. The dynamos are wound for a potential of 500 volts at no load, and 550 volts at full load, being over-compounded to that extent. The output of these machines is used for both stationary power and railway work.

One or more of these generators are used, according to demand, to supply power to the old station, operated by steam,



GENERATORS IN BRIDGE MILL POWER PLANT.

and located about three-quarters of a mile from the water power plant. In this old station is located all the alternating and arc machinery of the Pawtucket Electric Company.

CONCLUSION.

Mr. D. L. Goff, president of the consolidated company, has given almost his entire time for the past three years to every detail of this electric and water power plant. He has been ably seconded by his right hand man, Mr. George O. Capron, and to them is largely due the credit of producing what is considered to be the finest water power electric station in New England.

As the plant was nearing completion, the Bridge Mill Power Company obtained a contract to furnish power to the Interstate Railway, an electric line running between Pawtucket and Attleborough, and in addition were doing considerable motor work. They had also secured from the Legislature and from the City Council valuable franchises permitting the use of the streets for poles and wires, with the same privileges possessed by the Gas Company and under the same restrictions. They were likely also to be competitors for the city lighting at no distant day when the contract with the Gas Company expired.

It soon became evident to both parties, each strong in its own position, the one with its established business, and the other sure to become a troublesome rival from its more central location, its water power, and its modern and labor saving apparatus, that a consolidation was not only advisable, but almost inevitable. Hence the union which was consummated in May last. Six months business of the new company has proved the wisdom of the step in increased net earnings, and the outlook for a large and prosperous career is very bright. The officers of the company are: D. L. Goff, president; G. M. Thornton, vice-president; F. W. Easton, secretary; H. A. Pierce, treasurer and general manager.

EXPERIENCE WITH WELSBACH COMPETITION.

A leading central station manager in a large city writes us: "We have had more trouble from Welsbach burners this fall than ever before. It is fair to assume that the majority of our customers are using the Welsbach and only use incandescent light in the windows. We have to the present time been able to keep up our business regardless of this fact. I am not very much dissipirited as to the final result of the Welsbach, as I believe that the character of the light, the heat, etc., are going to drive it out eventually. Still, it is an evidence of the progress which is being made to utilize gas, while the electrical people are, so far as I know, sitting still almost in the spirit that everything has been accomplished. I have repeatedly urged that it is of the most vital importance to electric light people and the extension of their business that higher candle power be produced with the same energy as is now required by 16 candle-power lamps."

"ARE CENTRAL STATIONS DOOMED?"

BY "ENGINEER."

THIS is the heading which I find in the Dec. 2 issue of The Electrical Engineer. The best test of superficial reasoning or incorrect theory is experiment and I therefore venture to place before your readers the actual results of an existing Edison station and the profits of the same, leaving them to infer what they may from the facts. Names and localities are omitted, but the facts are correct.

The company was organized in 1887, with $1,000,000 capital, and the writer appointed engineer. The station began operations in March, 1889. It made money almost from the outset. Between 1887 and 1892 it had four presidents, all alike, directly or indirectly, drawing liberal salaries, and while differing in many respects, all frankly owning that they practically knew nothing of the business, which they must have felt divinely inspired to direct and get pay from.

In 1892 company matters had gotten into such a condition that the "business men" of the board preferred not to be prominently connected with its management. Its full paid stock had been sold at a forced sale at $45 for $100 and many private sales were made at $75. It was of no value as collateral. It had paid the parent company $335,000 stock for patents and to another company $75,000 for useless conduits and was paying other royalties and expenses all the time. It had its station completed to one-half its capacity. It had issued $300,000 in 6 per cent. debentures, and it could not manage to pay a dividend. The ship if not a wreck was certainly settling under the directors' noses. Some president must be found who would willingly or unwillingly sacrifice himself, so the board elected their engineer and manager to be president.

At the end of four years, in 1896, this same board of directors sold their works for $2,800,000 cash, and had not a dollar of indebtedness to pay, receiving a large bonus for material and accounts.

How was this brought about? Fortunately the engineer who felt so highly flattered (?) by his election to the presidency, was a skilled accountant, and it did not take him long after finding the trap he was in to realize that "something must be done," and above all things that the 6 per cent. bonds and their sinking fund of $25,000 per annum must be wiped out, so that the earnings of the company could go to the stockholders as dividends.

The station all this time was increasing its business and earning profits, but interest, sinking fund, and sinecure salaries were eating up what little was left after such increases of plant as were absolutely necessary were paid for.

The capital stock was increased to $2,000,000. The station machinery was completed to its full feeder capacity and the bonds were retired with a portion of the proceeds of the stock. This could not be done until a dividend was paid which was declared April 1, 1892.

A stockholder having 100 shares of the stock in January, 1892, had received by 1896, the following amounts:

	Profit.	Investment
	$4,000	$10,000
1892—Oct. 1, 7% cash	700	
20% stock at $1.40	2,800	
Dec. 31, 2% on 120 shares	240	
1894—March 31, 12% stock on 120 shares	1,440	
5% stock at $1.40	840	
1895—Dec. 31, 16% on 125 shares	2,000	
Besides receiving 25% stock dividend to cover profits invested in plant he was given the option of 75 shares at par worth at the time of sale, 140	3,000	$7,500
Dividends on purchased allotments	1,267	
	$16,287	$17,500

The stock of this company was exchanged for a 5 per cent. bond of equal value and $50 cash for each share. The bonds are now selling at 90 and therefore the stock is valued at 140 in estimate. The total profit was 93 per cent., or 23 per cent. per annum for the four years in the case of a stockholder, who retained what stock he had and took what he was offered for four years after 1892. The stock having risen from $75 to $140 per share, a stockholder who invested in 1887 would on a careful computation be found to have received upwards of 12 per cent. per annum, but it is sufficient for our purpose to show that the intrinsic merit of Edison's wonderful invention of the incandescent light is so great as to cause it to survive management that would be ruinous to any other business placed in the hands of speculators and unskilled men, as it is, and that with average good management it can be made to pay large profits.

There is little for central stations to fear—when they have fairly able and economical management (and the larger they are the cheaper they can sell light and power)—from small plants, such as the "block system;" but the impression that these central station and other electric stocks are unsafe or are unprofitable is gaining ground for another reason.

The same company that purchased the Edison station, to which reference has been made, for $2,000,000 in bonds and $1,000,000 in cash, have also purchased another electric company whose whole plant could to-day be duplicated for $1,000,000.

On their two plants worth	$3,000,000	
They have issued bonds		2,000,000
Preferred stock, 60 per cent. paid		3,000,000
Common stock		5,000,000
		$10,000,000
Water		$7,000,000

The preferred stock is not as yet fully paid in, but it will undoubtedly all be called. The common stock is given away. Speculation has been fast and furious, but some day the tide will turn and the water will be squeezed out of this stock as remorselessly as it has been in the case of the General Electric and the Westinghouse companies.

It hardly appears to the writer that "central stations are doomed," but the prevailing methods of stock manipulation are, and the sooner laws are enacted to prevent over-capitalization of these municipal lighting companies the sooner will the public be relieved from the impositions arising from the attempts of the companies to take from them four or five times a legitimate profit, and the stockholders will then feel secure that public opinion will not force legislation that will render their stock valueless, although they may be innocent holders, the victims of the adroit schemes of others.

"To insure to honest industry a just reward and to commercial enterprise a legitimate profit" (Pitt) should be the aim of our commercial laws, and all good citizens should frown on methods of business which work to the contrary, or Bryanism will grow, and like the rain, fall alike on the just and the unjust.

THE ELECTRIC ARC FOR LANTERN PROJECTION.—II.

BY E. P. HOPKINS.

WE will now describe the requirements necessary in the electric projection lamp different from those of the standard arc lamp for commercial purposes.

The lamp must operate in other positions than the vertical as the carbons have to be tilted away from the condensers to obtain the best light, and in practice it is generally necessary to tilt the lantern upwards to reach the center of the screen, so that sometimes it is impossible to use a gravity feed lamp; so for this and other reasons a spring-actuated movement is used which avoids all trouble in this direction, and if the parts become dirty, the spring will force the carbons together, irrespective of the position of the lamp.

When the arc lamp is in inexperienced hands it is very necessary that it should burn equally well with a small current as with a heavy one so that it cannot be burnt out. This is accomplished by using only a shunt regulating magnet of high resistance, and a small striking magnet of very heavy wire, which in the lamps now constructed will operate with 4 amperes or with as high as 20 amperes. Such lamps have often had 30 amperes passed through them, and in one case 60 amperes; the only effect being the burning of the insulation of the wire of the striking magnet on the negative carbon holder.

Perhaps oe of the most important points from the standpoint of the audience is a single adjustment in all directions and the alignment of the carbons, which is so arranged that the position of the carbons can be changed while the lamp is burning and the fingers not burnt, as the parts handled are well protected from the heat.

Fig. 6 shows the lamp complete with adjustable support and hood to keep in the light when attached to the lantern. Fig. 7 shows the lamp with the two side plates of the mechanism case removed, and also the hood. Fig. 8 shows the diagram of circuits and the detail of mechanism.

In Fig. 6 the know A is fixed to the main shaft of the movement which engages by pinions with two racks, both of which enter the top of the mechanism box. The upper carbon holder rack is guided by a sliding collar on the fixed guide bar shown in Fig. 7. From the sliding collar projects a lug through which the knob D screws; this screw presses against a lug projecting downwards from the carbon holder, which swings on the upper part of the sliding collar and is held against the end of screw D by a steel spring fixed to the top of the rack so that the carbon holder is always kept

in contact with the thumbscrew, D, and thus a most accurate lateral adjustment is produced.

Immediately above screw D in Fig. 6 are two screws; these support and at the same time insulate by mica the upper or positive carbon holder, the connection being made by a flexible conductor directly fastened to one of the binding posts of the lamp and the other end to a lug which forms part of the same casting as the carbon holder clamp. This casting

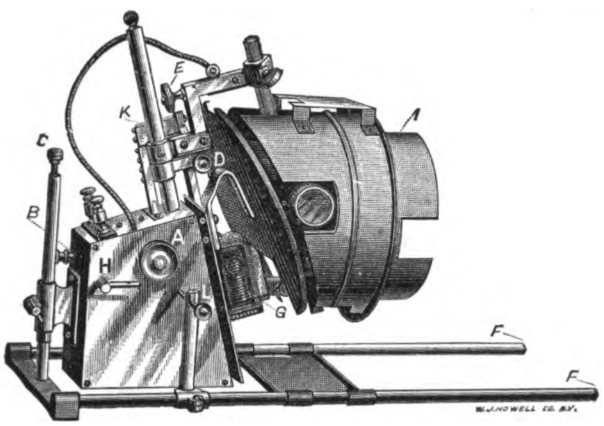


Fig. 6.

of the lug and clamps slide in a slot cut in the carbon holder arm, the former being moved back and forth and held in position by the adjusting screw E, Fig. 6. The knob of this screw is of black fiber, so that it can be handled when the lamp is burning; this is found to be very necessary when starting with new carbons and a perfectly equal illumination on the screen is required. After burning for about fifteen minutes, when the point of the upper carbon is properly shaped, it is advisable to advance the upper carbon so as to bring it more into line with the lower carbon until the carbons are about in the position as shown in Fig. 7.

The guide of the lower carbon rack K, Fig. 6, is a plate which slides on the front of the lamp, carrying at its lower extremity the striking magnet G. H is a lever to release by hand the movement to bring the carbons together if they are too far apart and the current is not turned on.

The lamp is supported by a clamp at the back of the movement box which firmly holds a tube stopped at the top by a

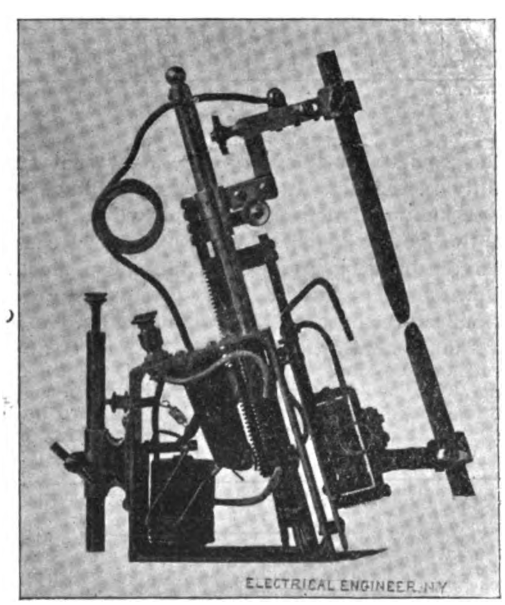

Fig. 7.—Colt Projection Arc Lamp.

plug through which screws the knob C. In passing into the tube it rests upon the top of the supporting post which fits loosely inside the tube, so that by turning the screw C in or out, the lamp will be raised or lowered, respectively, the weight of the lamp always keeping the screw C in close contact with the top of the supporting post so that there is no lost motion.

For quick adjustment the clamp on the back of the lamp, Fig. 8, is loosened and moved up or down the tube. L is the screw knob for the lateral adjustment, screwing through the upright post which is clamped to the guide rod F. The point of the thumb screw will push the lamp to one side, swinging on the back post and screw C. There is a spring pressing against the opposite side of the lamp which, being clamped to the other guide bar F, keeps the lamp in contact with the point of the thumb screw L. A small iron tray resting between the guide bars FF catches carbon dust and sparks that may fall.

The hood I is so constructed that there is ample space for ventilation and at the same time prevents the escape of light as much as possible. There is also a peep hole covered with very deep ruby glass, which appears black to everything else except the sun, through which the arc can be easily watched without hurting the eyes.

Fig. 7 shows the mechanism box with the side taken off and together with Fig. 8 illustrates clearly the entire working and circuits of the lamp. The spring movement is a train of three spindles with a verge escapement at R. On the main shaft 1 is the mainspring, one end fixed to the shaft and the other to the post of the movement frame. Spindle 1 moves the main gear by ratchet and pawl T, the pinions engaging with the two racks, V U. Being fixed to the shaft, when the latter is moved, the two racks, and therefore the carbon holders X Y, will move with them.

If the shaft is so turned that the carbon holders are separated, the mainspring, being fixed to this shaft, will be wound up, so that when new carbons are put in the lamp the spring will necessarily be wound up at the same time. The shaft 1 is moved by knob A, Fig. 6, so that the carbons can be separated while the lamp is burning.

In Fig. 8 the escapement tail Q engages with the catch P,

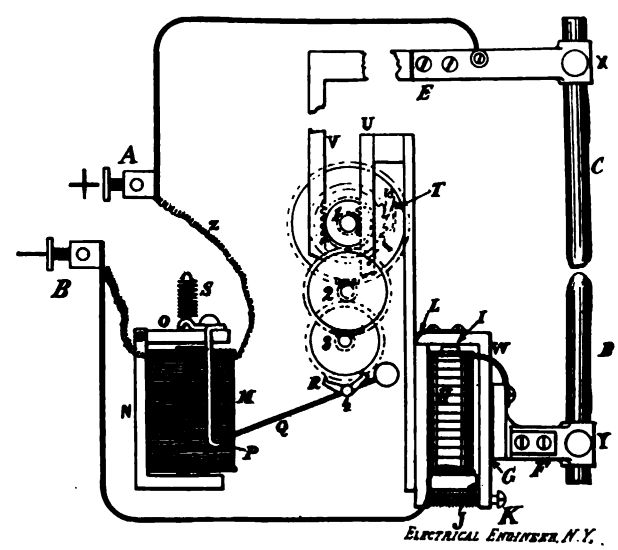

Fig. 8.

fixed to the armature O of regulating shunt magnet M, the retractile spring S being adjusted by the lock thumb screw B, Fig. 6, which is outside the body of the lamp. The armature O is pivoted on screw points passing through projections on the yoke N.

The operation of the lamp is as follows: After separating the carbon holders as far as possible by turning the knob A, Fig. 6, and inserting the carbons, connect up the positive main to binding post A and the negative to binding post B. Suppose the carbons are in the position shown in Figs. 7 and 8. No current will pass, as the carbons do not touch, and the carbon holders are insulated with mica at E and G; but the shunt magnet M will be energized, attracting armature O and catch P, thus releasing tail Q and escapement R, allowing the main spring to run down and to lower the upper carbon and raise the lower one until they come in contact; then the current flowing through the carbons and the series striking magnet H will draw down its armature at the two poles I and J and with it the holder Y, thus striking the arc. When the arc becomes too long the shunt magnet becomes stronger, releasing the movement and so shortening the arc until the magnet releases its armature.

On account of the escapement tail Q being long. there is very little friction for the armature O to overcome, so that the regulation is very close, sometimes regulating within 1 volt of change with 45 volts between the carbon points.

Once having adjusted the arc for a small current up to 6 amperes or less, almost any amount of current may be used, without affecting materially the mechanism or steadiness of the arc which will burn a little longer with more current, the mechanism automatically producing this change. Thirty amperes has been used with success; the only part that appeared to suffer was the insulation on the striking magnet H, but on account of its extremely low resistance it still operates when all the insulation is burnt off, there not being enough voltage between each layer to force the current through the oxydized surface of the copper wire.

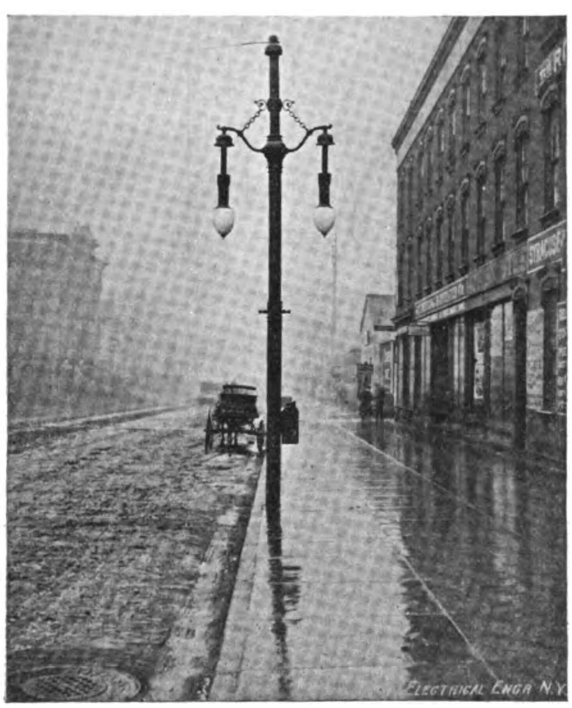
In order to avoid the heat of the arc a metal plate is fastened to the front of the mechanism box by four screws and deep washers which allows a good circulation of air to carry off the heat, besides the sheet iron hood shown in Fig. 6.

The lamp is very small and light, weighing only 6 lbs. The mechanism box 4⅝ inches long on the base, 3¼ inches long on top, 5⅛ inches high, width 2 inches; total height, 11 inches. This allows the lamp to burn about 2½ hours with 7-16 inch carbons and 12 amperes, with an upper carbon 8 inches long and lower carbon 4 inches long.

In Fig. 7 is shown an extra resistance of German silver wire which is connected in series with the shunt regulating magnet; this is to prevent the heating of the magnet M causing the latter to increase in resistance and so change the regulation by burning with a longer arc. By increasing the length of the carbon holders and by shunting part of the current from the striking magnet there is no limit to the amount of amperes that may be used with this lamp.

ARC LIGHTING IN THE CITY OF ROCHESTER N. Y.

IT may well be doubted whether any city in the Union is better lighted than Rochester, N. Y. The city has a population of 160,000, and has 4,100 arc lights, of which 2,200 are employed for street lighting purposes. This is a splendid showing, and is the more remarkable in contrast with that of



CANDELABRA ARC LIGHT POLE, ROCHESTER, N. Y.

Buffalo, which, although now calling itself the "Electric City," has by no means treated its local electric lighting enterprises with encouraging liberality. This disparity has attracted attention in both cities, and a representative of Dun's Commercial Agency said recently: "The city of Rochester is the best example in this respect in America. Between each business block they have six ornamental iron columns to which are suspended two huge milk glass arc light globes of very handsome pattern, in fact, the handsomest electric lamp-post in America. They have the appearance of candelabra, and belong to a progressive, wide-awake, metropolitan city. They would be thoroughly in keeping with Buffalo's matchless paved streets." Commenting further on the distribution of the lights, this observant critic said: "Buffalo has twenty-five arc lights within seven blocks on Main street, from Exchange to Genesee, while Rochester has in the same distance on her main street 174 arc lights of handsome design."

We illustrate herewith one of the Rochester posts, from a photograph kindly taken for us by Mr. George A. Redman, the general manager of the Rochester Gas and Electric Co. The poles are made of iron pipe, 8 inches at the bottom, 7 inches at the centre, and 6 inches in the upper part. About 18 inches of the top, including the cap, is of wood, to which the electric railway span wires are attached. The poles are owned by the street railway and the Gas and Electric Co., who now have about 210 in use. The Post-office authorities are employing them as supports for letter boxes, and experience no trouble whatever from the current. The poles stand 19 feet in height, and the rows of them up and down the streets, carrying milk glass globes, are a very pretty sight. The poles were built by the Walworth Mfg. Co., of Boston. The city officials who have had charge of the work for the city were Mr. Charles R. Barnes, city electrician, and Alderman A. H. Dewey, chairman of the Lamp and Electric Committee. Now that Buffalo has again to settle its lighting question, many of its citizens are hoping that their streets may be able to compare with those of the sister city.

POWER TRANSMISSION.

THE CHURCHWARD EQUALIZER SYSTEM OF DISTRIBUTION.

BY A. CHURCHWARD.

DURING the past few years many ingenious systems have been devised to get an economical system of power transmission, which shall have at least the copper economy of the three-wire system, without some of its drawbacks. The following is a description of such a system, which I have had in use in a central station in New York City for the past three years without a breakdown in the balance of the two cir-

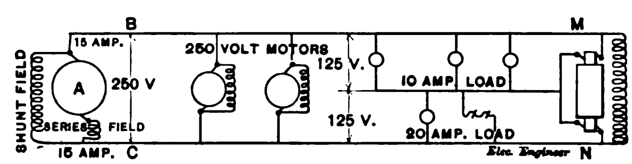


FIG. 1.

cuits. The capacity of this station is at present 1,200 k. w., and steadily increasing. In three years we have not lost a lamp from an unbalance of the light wires, and the character of the power supplied is very mixed, consisting of motors driving printing presses, machine shop, elevators, etc., arc and incandescent lamps.

Fig. 1 shows the system diagrammatically. A is a compound wound generator, 250 volts. B and C are the two mains leading to points of distribution. D is the central, or equalizing wire, used only in the district where lights are supplied. Suppose the two sides of the circuit to be balanced, then the current will flow from the generator through B to D

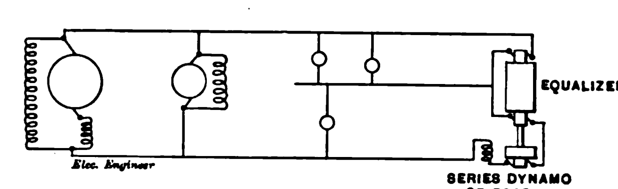

FIG. 3.

to C. But if the circuits are unbalanced, for instance 10 amperes between B and D, and 20 amperes between D and C, then 15 amperes at 250 volts will have to be supplied by the generator A. Ten amperes will flow from B to D through the lamps, the remaining 5 amperes will flow through the armature winding M of the equalizer, that end then be-

coming a motor; this will in turn cause the other winding N to become a dynamo and supply the necessary 5 amperes to complete the 20 amperes needed by the circuit between D and C.

In this system we have a single generator of 250 volts and a small machine which we call the equalizer, which is placed at the centre of distribution of the incandescent and arc

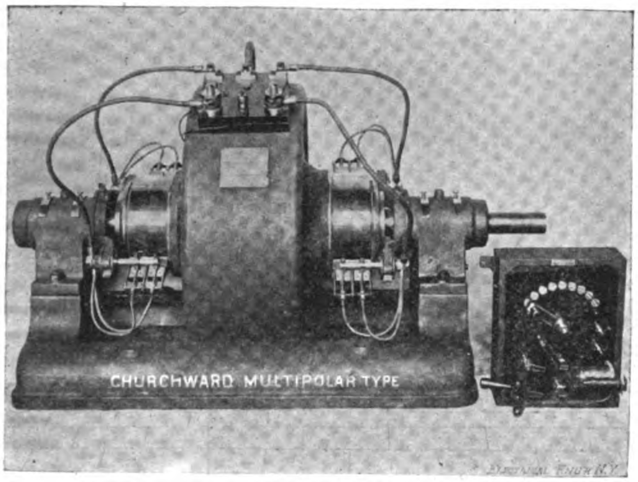

FIG. 2.—EXCELSIOR ELECTRIC CO.'S EQUALIZER.

lamps which supplies the third wire for lighting. The power is taken direct from the two outside wires, or, in other words, direct from the generator, while the equalizer is only used to preserve the balance in the lighting circuits. The standard proportion which we have adopted for the equalizer is 10 per cent. of the kilowatt capacity of the total lamps on the circuit.

In actual practice, however, an am-meter in the middle wire scarcely ever shows more than 3 per cent. unbalance, but

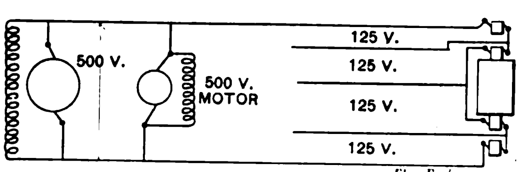

FIG. 4.

the extra capacity of the equalizer acts as a safeguard against short circuits, etc., or where focusing lamps, or arc lamps, are likely to be used on one side only. Thus, in a system using 100 k. w., viz., 50 k. w. in motors and 50 k. w. in lights, the size of the equalizer would only be 5 k. w., and cost very much less than a third or neutral wire from the generator to the point of distribution.

The equalizing machine shown in Fig. 2 has a single armature core having two independent windings connected to two commutators placed one on each end of the armature. One set of field magnets are employed, the coils of which are connected in shunt to the 250 volt mains. This gives only one field loss, one loss due to hysteresis and eddy currents, and only one set of bearings; and as the armature windings are

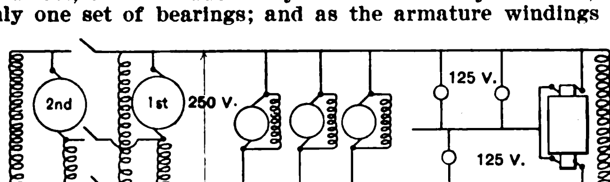

FIG. 5.

connected in opposition to each other where the machine is equalizing, there can be no armature reaction, no drop in speed, no sparking at brushes with change of load, so that the load limit of the machine is the carrying capacity of the armature wires. When the circuits are balanced the equalizers run free as a shunt motor across the 250 volt mains, ready to take care of the unbalance the moment it occurs.

Still another advantage of this system is that we can always compensate for the drop in the line at any point independently of others.

What might be called a "booster equalizer system" is shown in Fig. 3. When the heaviest loads are on the system and the sides balanced, all the equalizer does is to run free as a motor. Now by attaching a small series dynamo to the end of the shaft of the equalizer, and adjusting it to the load and drop, we can first boost the pressure and then equalize it; so that, given a district with various points of distribution, and various drops, we can run even the longest and heaviest loaded circuits at the same pressure as at the station.

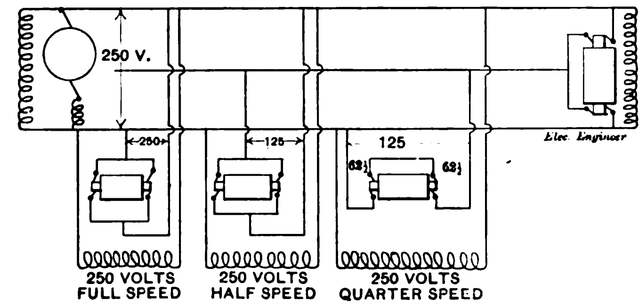

FIG. 6.

The equalizer system illustrated in Fig. 4 is not limited to 250 volts. Where a company has a motor trade much scattered, they can use, for instance, 500 volts, and run a long distance with economy, and put an equalizer in the centre of the lighting district and supply customers at 110 to 125 volts.

Having given a description of the system for power transmission from central stations, let us turn our attention to its special advantages in a factory. See Fig. 5.

To begin with, we change to electricity to overcome the losses due to belts and long lines of shafting. In the ordinary three-wire system we have two 50 k. w. machines (in a 100 k. w. installation) if in the day time the load averages 50 k. w., but at night when the lights are necessary a 100 k. w. So that in the day time the machines are not running at the most efficient point, averaging only one-half load.

By using the equalizer system, we will still have two 50 k. w. machines, but in the day time only one generator is needed, the load averaging 50 k. w., and it is, therefore, running at its highest efficiency in the day time; in case of breakdown the other 50 k. w. will always act as a reserve, and at night the two machines will run in multiple. See Figs. 5 and 6.

In many places where motors are used, variable speeds are required. If we use a resistance, we cut down the plant's

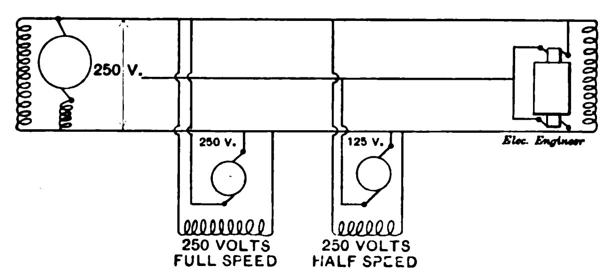

FIG. 7.

efficiency, and the speed will not be constant, but will vary with the load. Now, by having the equalizer larger than is necessary to balance the lights, the three wires can be used as a means of running the motors at a varying speed without the energy being consumed in resistance. By connecting the armature across 125 volts, and the fields across 250 volts, we can run the motor at a constant speed at one-half its normal, Figs. 6 and 7.

By making a special motor, with two commutators, or, in other words, using an equalizer, as a motor, we can reduce the speed to one-quarter, quickly, safely and economically, or any other speed desired can be obtained by varying the ratio between the two windings on the same armature core. And by having a resistance in the field circuit, the speed can be adjusted between any of two fixed points. When a heavy starting torque is required, as in cranes, elevators, etc., it will be self-evident that by these combinations, we can get the best results with the smallest waste of energy. A system possessing all these important advantages, certainly is worthy of consideration by engineers installing power plants.

THREE PHASE POWER TRANSMISSION AT ITASCA, WIS.

An interesting though small three-phase power transmission plant has been installed ot Itasca, Wis., just east of Superior, the division headquarters of the Chicago, St. Paul, Minneapolis and Omaha Railroad Co. At this point the shops roundhouses and storerooms of the railroad are located, and in their operation the company utilizes power for an average of 12 hours per day and steam the entire 24. About a mile and a quarter away from Itasca extensive docks have recently been built, and on them has been constructed a warehouse 1,500 feet long and 300 feet wide. Boats are loaded and unloaded on one side of the dock, tracks are laid on the entire length of the opposite side, and the cars load and unload their freight at any point in the warehouse.

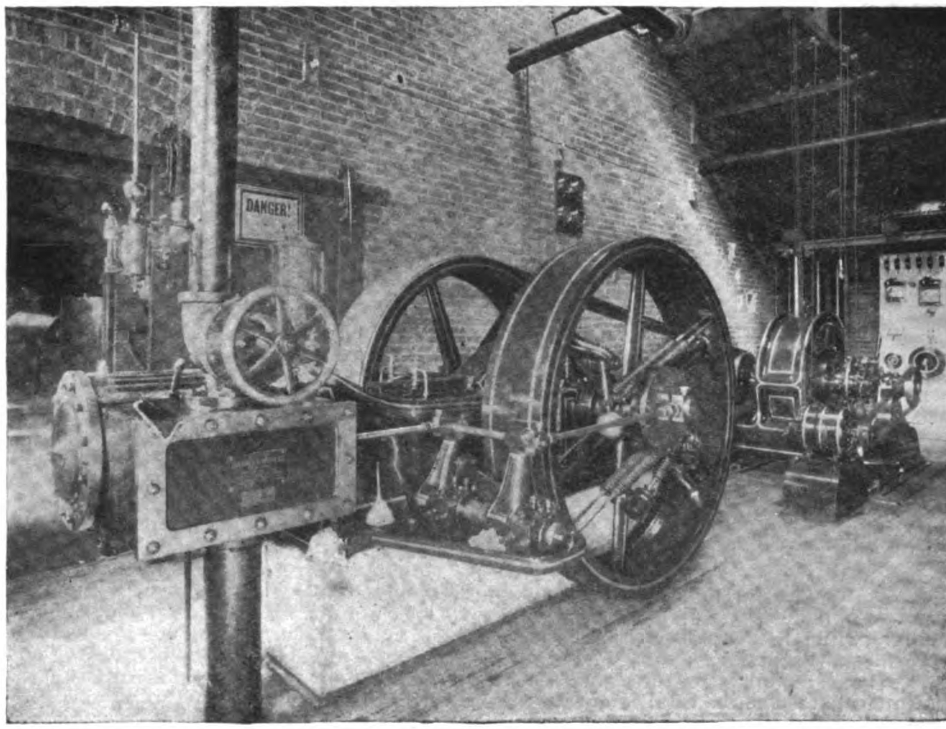

FIG. 1.—BALL & WOOD ENGINE AND GENERAL ELECTRIC 3-PHASE GENERATOR IN 3-PHASE PLANT AT ITASCA, WIS.

The protection of the warehouse from fire, containing as it does, many thousand dollars worth of property, was one of the first considerations after the construction of the buildings. and, naturally, the first idea was the purchase of a steam plant

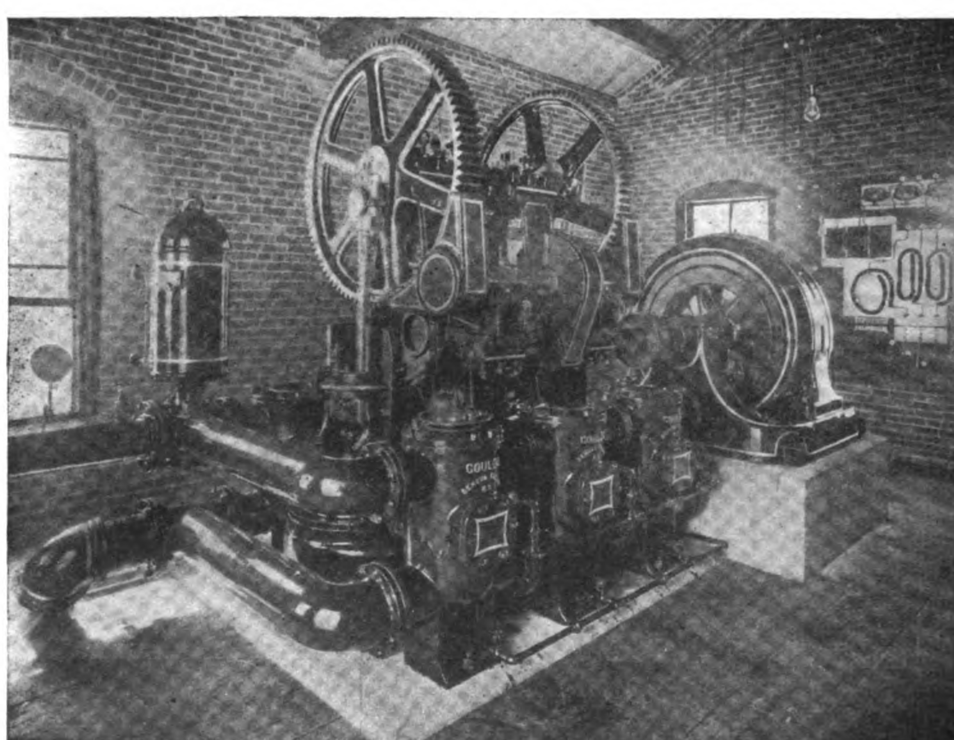

FIG 2.—PUMPING PLANT IN WAREHOUSE.

and pump. About this time the attention of the railway company was called to the numerous power transmission plants which the General Electric Company had installed, and they were not slow to take advantage of the merits of the three-phase system of transmission. Electricity carried the day, and at the present moment a 750-gallon pump is operating, and incandescent and arc lamps are scattered over the warehouse and dock, the shops, roundhouse and other buildings at Itasca, all operated by current from the power plant.

The current is generated by a General Electric 100 kilowatt three-phase generator, at a voltage of 2,000 volts, this pressure having been adopted in order to do away with the necessity of step-up transformers. The engine is driven at a speed of 900 revolutions per minute by a Ball & Wood engine of 110 horse power. At the dock the pumping plant is installed. This consists of a 75 General Electric 2,000-volt induction motor coupled to a Gould double-acting pump, having an output of 750 gallons per minute, operating at 80 pounds pressure and competent to throw four effective fire streams upon the docks and into the warehouse.

Mr. H. C. Hope, the superintendent of telegraphs and signals for the railroad company, states that the plant is one of the most perfect working light and power plants he has ever seen. All kinds of tests have been made with it, and the results have been satisfactory.

The dock warehouse is 1,500 feet long, and the inside is provided with five fire stations, fitted with electric fire alarm apparatus for transmitting signals between the docks and the engine house; also switches connecting the motor and the pump to the power wires. Hydrants and reels are suspended from the walls, each reel having 100 feet of hose, so that after the fire signal has been given from the engine house, one man can carry hose and water to the fire in from 10 to 30 seconds. A fire corps has been organized, and the men are drilled three times each week.

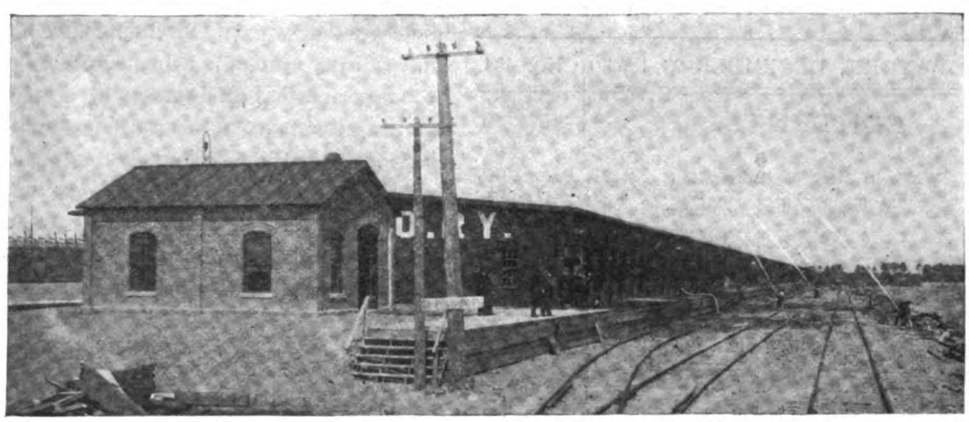

FIG. 3.—WAREHOUSE AND DOCK SHOWING STREAMS OF WATER.

The economy of this plant is markedly appreciated by the railway company. It has enabled them to save the expense of an engine and pumping plant at the dock, which means boilers, engines and all the various expensive accoutrements of such a plant and the maintenance of an engineer and an assistant, besides effecting considerable economy in the operating expenses. In addition to current furnished the pump, the generator also supplies electricity to twelve alternating current arc lamps, six on each side of the dock, supported on brackets from the sides of the building. Over 200 sixteen candle power lamps are required to light the warehouse, and in Itasca itself about 150 more sixteen candle power incandescent lamps are also installed.

This installation is a show plant in that district, and no railroad man who visits Itasca is allowed to depart before he has been shown the pumping plant. The insurance companies have also expressed considerable satisfaction at the adoption of electricity.

A CORRECTION.

An error crept into the article by Prof. Anthony on "A Method of Speed Control for Electric Motors," in our last issue. In the middle of the last paragraph but one, it says: "At the low speed the capacity would be unnecessarily small," etc. For "small" read "large."

POWER FROM PEAT.—There is a scheme on foot to furnish electric power to the City of Mexico from peat beds nine miles distant, owned by Boston interests.

ELECTRIC TRANSPORTATION.

ELECTRIC RAILWAY EXTENSION IN CONNECTICUT.

The New York, New Haven and Hartford Railroad is about to contract for a power house and two 850-kilowatt dynamos, to cost more than $100,000, for its new electrical plant at Berlin, Conn. With this equipment it proposes to meet competition by trolley parallels. The motive power will be for the Middletown and New Britain branches of the New Haven and the single track branch of the New England, between New Britain and Hartford.

A special dispatch from New Haven, Conn., of Dec. 15, says: As the session of the State Legislature draws near, it becomes evident that the number of new trolley schemes will exceed even the great record of the session of 1893, and that the conflict of the New Haven Company with the electric companies will be a very severe one. There will be more points of antagonism between the steam and trolley interests than ever heretofore, and the steam companies will have to fight, not only existing and operating trolley companies, but not a few new ones on paper seeking charters merely for the purpose of selling them.

Among proposed companies which have made or will soon make petition to the Legislature is one proposing to build from Milford to Stratford, which would connect the New Haven trolley system with that of the Bridgeport Traction Company, and also proposes an extension northward to Derby, Ansonia, and Shelton. Another proposes a line westward from New Haven through Woodbridge to Seymour; and yet another plan is for the extension of the Bristol and Plainville line through Terryville and Plymouth to Thomaston, where it would tap the Naugatuck valley. All these are either direct parallels of steam lines, or short "cut-offs" between steam roads more serious in competition than parallels. Already the length of these proposed parallels or "cut-offs" affecting steam roads amounts to about 140 miles, or about one-third more than the whole mileage of existing trolley parallels, which is largely made up of old horse railroads electrified. The figures are an index of the dimensions of the approaching steam-trolley contest, with the opening of the Legislative session still three weeks hence.

ELECTRIC RAILWAY WORK IN CHICAGO.

A mortgage for $3,000,000, covering all of the real and personal property, right, and franchises now owned by the Suburban Railroad Company, to the Chicago Title and Trust Company has been filed for record. It is given to secure an issue of twenty-year 5 per cent. gold interest-bearing bonds, to be dated March 2, 1896, and mature in 1916. An immediate issue of $1,250,000 of the bonds will be made, with which the company will build a double-track road from Harrison and West Forty-eighth streets west through Cicero and Harlem to Desplaines avenue. It will also build a double-track road in Twenty-second street in Cicero, and another in Robinson avenue. It is also to defray the expenses of equipping with electricity the line of railroad in Cicero. The remaining $1,750,000 will be used to purchase additional equipment and right of way.

VOL. XXII. NEW YORK, DECEMBER 23, 1896. No. 451.

CONTENTS.

ELECTRIC RAILWAY WORK IN NEW YORK.

In a letter addressed to the daily press last week, General Herman L. Haupt, who is prominently identified with one of the companies whose compressed air motors have been on trial on the tracks of the 125th street line in New York, presents the advantages of this type of motor for street railway traffic, as compared with electric traction, whether overhead trolley, or conduit. Of course he recites all the old, threadbare "drawbacks" and "dangers" that were the former stock in trade of cable railway promoters and the old fogies of the bad old horse car days, but which railway men from Maine to California now smile at. Unfortunately for General Haupt, his project comes too late as the management of the Metropolitan Railway Company, of New York, has already decided, after mature deliberation, to adopt electric traction and with it the conduit system. As already announced, it is intended to equip shortly the Fourth, Sixth and Eighth avenues electrically, and we understand that the company is now negotiating for 600 electric cars to operate these lines. As regards the underground system to be adopted, we learn that the Love conduit railway system is being favorably considered, and indeed it is reported that an offer has been made to the Love Electric Railway Company, to install its system on forty miles of railway, provided the latter company agrees to change over, gratis, the Lexington avenue cable road to the new system. But whichever system is adopted its success is assured. Of course "troubles" are to be expected before an extensive system of this nature is in thorough working order, but in the meantime we may expect to see the most made of these installation defects by the opponents of the electric system.

But though we disagree entirely with the advocates of the compressed air system we are bound to admire their pluck. Not content with the surface railways they are actually contemplating to tackle the elevated railway system of New York, on which an experimental compressed air locomotive is soon to be tested. This is truly jumping from the frying pan into the fire. The conditions of working on these roads is so exacting that success seems almost hopeless. Not that a locomotive with sufficient power cannot be designed, for that is a comparatively easy matter; but actual operation, we are convinced, will require so large a quantity of reserve power to be carried as to make the weights to be hauled impracticable. Thus it is proposed to carry in reserve about one-quarter or one-third the quantity of air beyond that necessary for a round trip. Yet in cases of accident locomotives on the elevated roads have been compelled to travel distances of nearly twice the length of the round trip, and in addition haul in a disabled

train. Then, again, in wet weather with slippery tracks a slip of 25 per cent. and more has been noted covering a round trip. This means nothing in the case of the steam or electric locomotive, beyond a loss of so much energy pure and simple; but in the case of the compressed air locomotive it might mean a complete exhaustion of the source of power before the trip is finished. One can better imagine than describe the condition of affairs on the elevated roads with two or three air locomotives unable to move for lack of power. We wish our compressed air friends no ill, but would advise them for their own peace of mind and safety of pocket to let the elevated railway severely alone; and, if they must engage in railway work, to confine themselves to the surface of the ground.

Apropos of the elevated roads the experimental storage battery locomotive now running on the Thirty-fourth street branch of the Third avenue line has shown up remarkably well. We are not at liberty to give the details of the results, but we have no hesitation in saying that they are surprising and we believe that they have made a most favorable impression on the elevated railway management. We confess the results are better than we expected.

ALL WITHIN ONE REIGN.

A CURIOUS reminder of the shortness of the period within which the great electrical discoveries and inventions have taken place is given in the clever little group etching just issued by Mr. Frank Paton, a clever and versatile English artist, whose work reminds one sometimes of Frith, sometimes of Landseer, sometimes of Cruikshank, but has always its own characteristics. Some of his work is very popular, in England, and we imagine that his "Recollections of a Record Reign" will enjoy a wide circulation. Copies of the etching have already found their way to this country. The center of the etching is a picture of an old mail coach bowling through Temple Bar in 1837, and then around are grouped a number of little sketches or portraits, one for each year down to 1896. For the year 1837, we find a sketch of the telegraph wires and poles; for 1866, a section of the Atlantic cable; for 1877, a kobold with the electric light chasing away a man with a gas meter; for 1879 the telephone set. Had Mr. Paton been living here he would certainly have rounded out his electrical notations with the modern trolley, but the average Englishman hardly yet knows that such a thing exists; so that much may be forgiven to an artist who is so well informed as to do justice in this graphic way to a number of other branches of electricity. It is indeed striking that all should have come within the period of a single reign, long though that reign was; and that the United States should have had so much to do with the invention and perfection of each of these arts.

A MODERN HYDRAULIC AND STEAM ELECTRIC PLANT.

EVEN in these days examples of good central station engineering are not as plentiful as one would like to see them, and hence good work in this department is all the more worthy of notice and study. One of the best recent examples is the Bridge Mill Power Company's station at Pawtucket, R. I., which possesses additional interest in that it represents a type of station which will become more common as time passes. There are many places where a large proportion of a water power is available during most of the year, and we commend to owners of such powers a study of the station described in this issue. Both the hydraulic and the auxiliary steam plant have been laid out with more than usual care, and the result has been an extremely economical rate of working. Among the several noteworthy features of this installation, the system of water wheel governing which has been adopted is specially worthy of mention. It is not so long since water wheel regulation for dynamo driving was still considered to be one of the things which might some day be accomplished. Indeed we recall instances where "regulation" is obtained by throwing resistances into the circuit equivalent to the load taken off the outside lines. The results obtained at Pawtucket will therefore be of special value as demonstrating an accomplished fact, in a very important branch of engineering.

ELECTRIC FOOT WARMERS.

THE idea of putting an incandescent lamp into a bed to serve as a foot warmer is ingenious, if not entirely new, but it requires care in its employment. Mr. Van Cott, of Unadilla, N. Y., went out skating, returned home with cold feet, and took a lamp to bed with him after warming his hands with it. The flexible cord was long enough to permit the use of the lamp in this way; but as the glass bulb had no wire guard, it got crushed by the feet of Mr. Van Cott while he slept. This did not awaken the tired skater, but as the current still remained on, the bed clothes soon caught fire, and Mr. Van Cott found his feet warmer than was altogether comfortable. He jumped out, friends came to his assistance, the fire was extinguished in the room, the bedding was thrown through the window to consume itself in the yard, and Mr. Van Cott now limps around on wounded feet, but with a larger knowledge of the principles of electricity. We do not wish to discourage such amateur trials, but would suggest that persons in need of electric foot warmers should not take unprotected lamps to bed with them, but should buy proper apparatus now on the market.

CENTRAL STATION ECONOMIES.

FEW articles have appeared in these pages of interest greater than that attaching to the narrative furnished to them for the current issue, dealing with the history of a large central station and with features of its management. This piquant, brilliant sketch has been called forth by the recent suggestive article of Mr. Max Osterberg, on the fate of central stations, and is another evidence of the fact that a lively discussion was set going by that gentleman when he took up the argument for isolated plants. The author of the article which we print this week is an engineer of the first eminence and he has told his story with a frankness which is simply starting. He certainly places it beyond cavil that central stations in good localities, if properly carried on, are enterprises of an excellent kind, and that there are sure to be more of them before there are fewer. We do not often see articles so plain and outspoken as that by "Engineer," and it is safe to predict that it will be read with very close attention.

FARE REDUCTION IN CHICAGO.

THERE appears to be no little stir on the subject of street car fares in Chicago, and a recent step has been the passing of an ordinance by the city authorities fixing a 4 cent fare. This, of course, the companies are fighting. Mr. Yerkes estimates the loss to the West Chicago road at $2,000,000 gross per annum. We doubt very much whether the roads can live under such a reduction, but we have no doubt on the point that by such a reduction the companies will have to cut down expenditures now borne with the object of increasing public facilities for travel.

TELEPHONY AND TELEGRAPHY.

THE DE VEAU SUBMARINE DIVER'S TELEPHONE HELMET.

A VERY ingenious and interesting form of telephone system for the use of divers operating in either shallow or deep water, has been invented and worked out by De Veau & Co., of 32 and 34 Frankfort street, New York. It is very clearly illustrated in the accompanying cuts, Figs. 1 and 2.

The main idea in such work must be, of course, to leave the diver as unhampered as possible when using such auxiliary

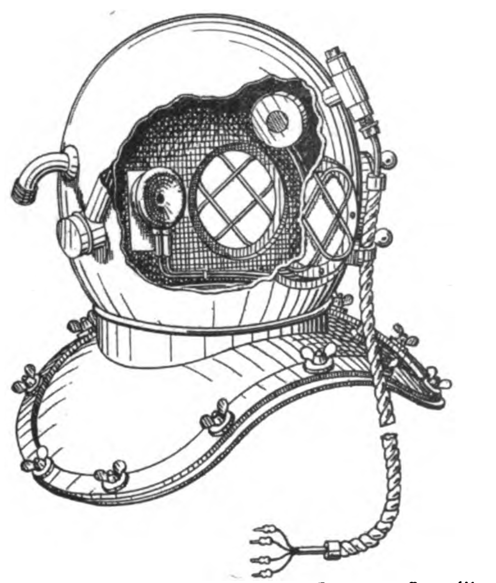

FIG. 1.—THE DE VEAU DIVER'S TELEPHONE HELMET.

devices. In other words, the presence of the telephone should change no conditions whatever, so far as making any demand on the diver's vigilance, activity or dexterity is concerned. In the engraving, Fig. 1, part of the helmet is shown cut away, in order that the arrangement of the apparatus within it may be seen and understood. The transmitter is just above the diver's head, and is No. 107 De Veau form. The receiver is closely adjacent to the left car, and is of the ordinary watch case type, No. 8½, as made by the firm. Both positions are

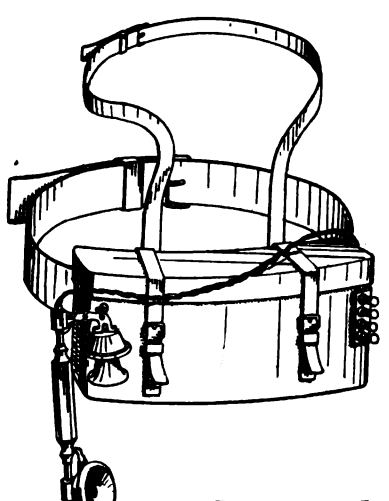

FIG. 2.—THE DE VEAU DIVER'S DECK TELEPHONE OUTFIT.

exactly suited to get the best effect from a conversation with the interlocutor at the surface. The circuit is formed by two wires, the lines running through the center of the manila rope, shown attached to the helmet. There is, as will be noted, a little junction box outside the helmet, and a little collar to relieve the strain that might come on the cable. Special pains were taken with this manila cable, which is wound with the spirals of the strands lying closely like those of a spring, and unusual protection is thus given to the insulated wires inside it.

Fig. 2 shows the box and set carried by the man on deck, strapped to his body, so as to relieve him also of extra demands on his hands or attention. In the box is the induction coil for the system, and all the accessories, including four cells of Mesco battery. The little switch on the deck set cuts in the battery for both. When the diver is not talking to the man on deck, and wants to attract attenion, all he has to do is to jerk his life line. The four binding posts on the box serve for the batteries and the two talking wires. It will thus be seen that the diver is relieved of all worry or concern about the apparatus. The man on deck "runs the exchange," so to speak. The gain in the speed with which the various diving operations are carried on with the aid of the telephone is remarkable. The weight of the apparatus is insignificant. The deck set weighs only about four pounds, and the diver's set adds only about eight ounces to the weight of the helmet.

THE ELIZABETH, N. J., TELEPHONE CO.

ONE of the best examples of an independent telephone exchange to be found in the East is that at Elizabeth, N. J. The Elizabeth exchange is young yet, less than a year old, but if it keeps on growing at the present rate it will before many years tax the energies of the best telephone engineering talent.

The distinguishing feature of the Elizabeth Telephone Company is its large list of stockholders, nearly all of whom are subscribers, thus making the concern almost wholly co-operative in its character.

The interests of the independent company are in the hands of James MacMaster, who fills the office of secretary, supported by a very efficient force of employés, who are made to feel that their own success depends greatly upon the success of the company. The system of accounts is of the simplest character, and so arranged that any officer of the company can at short notice at any time learn the condition of its finances. Mr. MacMasters believes in simplicity, and the doing of little things well.. The company now have 330 subscribers, and the list is growing rapidly.

One encouraging feature noted is that people are learning to use the telephone more, and the management believes there is no doubt that the time will come before many years have passed when the telephone will be on the desk of the merchant, the library table of the student, and even on the kitchen table of the housewife.

TROUBLE WITH THE RIVER AMAZON CABLE.

Consul Matthews writes the Department of State from Para that the Brazilian Government is having a hard time in trying to operate the new cable to Manaos. The cable, costing about $1,000,000, was guaranteed by the company for thirty days. On the thirty-first day it failed, and no message has been sent over it since last February. It is hoped to have it in working order by the end of the year. Engineers now assert that a cable up the Amazon cannot be made a success on account of the current and many obstructions in the river bed. The cable is of Siemens make, and one of the best ever laid, but the conditions are said to be worse than those encountered even by cables in the busy Hudson River.

IN A LONDON CHURCH.

A telephone has just been placed in the pulpit of St. Michael's, Chester square, in order that Canon Fleming's sermons may be heard by the inmates of the neighboring hospitals and by invalid parishoners.

SPOKANE, WASH.—The Spokane and Rossland Telegraph and Telephone Company has completed its first fifteen miles of line from Colville to Marcus and the instruments are being placed. The company will now push the work on the line both towards Rossland and Spokane, and hopes to connect the two cities by Jan. 1, 1897. A branch will also be built from Marcus to Grand Forks, connecting there with the local system of wires operated under the British charter. When this line is completed the whole mineral region lying in Stevens County, the reservation, and all the British Columbia mining camps will be connected up with and talk to Seattle direct.

LOCKPORT, N. Y.—The Bell Telephone Co. proposes to erect a new exchange at a cost of $10,000 and put its wires underground.

Roentgen Rays.

CURIOUS MOTIONS IN A CROOKES TUBE.

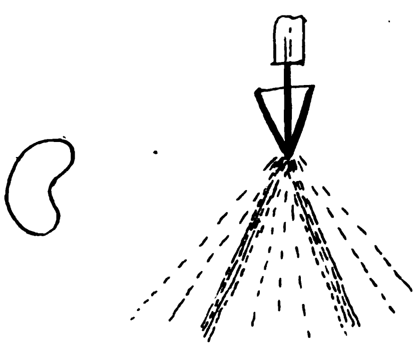
BY PROF W. C. PECKHAM.

WHILE making an exposure upon a patient with Röntgen rays a phenomenon occurred in the tube which seemed worthy of permanent record.

The tube was a Thomson double focus tube with adjustable vacuum, a most powerful tube, giving strong fluorescence and a flood of rays. At the time referred to there was lying on the bottom of the tube under the anode a crescent-shaped piece of glass, a thin cup-shaped sliver, which had been left in the tube during its manufacture. It lay on its rounded side like a watch glass lying on its convex side and was approximately a half inch long and a quarter of an inch wide. Fig. 1 represents its shape and size.

All at once it began to revolve and was soon whirling faster than the eye could follow, waltzing all by itself without a partner. After a little it came to rest. Again and yet again it went through this performance, stopping each time directly under the anode. Its next movement was to take a leap toward one of the anodes, to a distance of probably an inch and a half and immediately it jumped back again to its usual stopping place, alighting on its concave side, after which, of course, it lay still. This was seen by my patient as well as by myself.

In this tube the anode consists of a plate of platinum bent



FIGS. 1 AND 2.—CURIOUS MOTIONS IN A CROOKES TUBE.

into a V-shape. The tube was horizontal and placed so that the V was seen edgewise when looked down upon, and the piece of glass lay in the projection downwards of the bottom of the V. All who have used tubes whose anodes are the radiants of the X-rays, must have noticed in the fluoroscope the great difference in the intensity of the rays from the edge of the anode, giving a strongly shaded space as in the accompanying sketch, Fig. 2. This produces what I am accustomed to tell visitors is the only genuine X-ray.

The curious whirling of the piece of glass which was very thin and light indicates a greater intensity of action on one of its sides than the other. Or was it bombarded by material molecules driven out from the anode? By the way it was rendered visible in the dark room by its own fluorescence, it would not seem probable that cathode streams were the cause of this motion since there are focused on the anode about an inch above the piece of glass.

It might be that tubes could be constructed in which such a phenomenon could be produced with certainty by mounting a light vane of some dielectric directly under the edge of a V-shaped anode.

On the following day the piece of glass which had behaved with so much levity was found broken into several fragments, and has not done so any more.

THE PHOSPHORESCENCE OF FLUORESCENT SCREENS.

BY MARTIN P. RICE.

Referring to the subject of phosphorescence of fluorescent screens the following experiment affords a good illustration:

A Crookes tube, giving an abundant supply of Roentgen rays of high penetrative power, was excited by a powerful induction coil. A flat iron wrench was then placed against the screen of a fluoroscope and viewed in the usual way. On opening the switch in the primary the bright illumination of the screen ceased, but a very perceptible glow continued, making the dark shadow under the metal object plainly visible, although the tube was no longer excited.

After the primary circuit is broken, the metal object may be removed entirely from the screen, but its shadow will still appear surrounded by the glowing surface. If a completely darkened room is available for the experiment, the screen, after receiving the impression, may be handed around and viewed by different persons.

A number of different fluoroscopes were tested in this way for fluorescence, and all were found to possess the property to a greater or less degree.

X-RAYS HARMLESS WITH THE STATIC MACHINE.

BY G. A. FREI.

LAST summer I had a communication published in one of the electrical journals regarding the deleterious effect of the rays on the skin. As I said then, I have always been skeptical on the subject and at the time admitted the fact against my own convictions. With what I thought then to be the effects of the rays on my own hands it was practically a natural conclusion.

Since then I have persistently kept on with my experiments in that line and finally came to the conclusion that the effects which we perceive on the skin, the hair or nails, are not caused by the action of the X-rays in any way.

During last summer, and before the publication of my former communication, I carried on the experiments mostly with a 6-inch Ruhmkorff coil, reinforced at times by a step-up coil. Since then, however, my experiments were made almost exclusively with static machines, averaging an 8-inch continuous discharge. More time is devoted to them than last summer, and the apparatus is more powerful than that used at that time, yet neither myself nor any of the persons I ever experimented upon with the static machine have ever felt any ill-effects.

The remark has been made that possibly by this time the skin on my hands may not be so sensitive to the action of the rays and that therefore no effects are shown. To find out whether there can be such a thing as X-ray-proof skin, and at the same time whether there is really no bad effect on the skin when static machines are used for the production of X-rays, I started a series of experiments with my left foot. For several weeks I subjected it to the action of the rays every four days from half an hour to an hour at a time. The tube was brought as near the foot as possible without touching it, but up to the present there is neither discoloration nor any other of the now well-known effects to be seen or felt. This proves conclusively, at least as far as my own observations goes, that whatever ill-effects we get on our skin are caused only when we use induction coils of one form or another, while no such effects are perceived when we employ the static machine.

Many physicians bring forth the argument that the application of the X-rays might prove dangerous to their patients, that here a foot had to be amputated, then some one's finger nails dropped off, another has a sore of three months' standing, etc. Such arguments can be met with the above fact that the X-rays are not the direct cause of the trouble and with this fact established remedies could undoubtedly be found to reduce, if not entirely eliminate, the effect on the skin when coils are to be employed.

Letters to the Editor.

THERMO-ELECTRICITY AND THE JACQUES CELL.

Prof. W. A. Anthony, in his letter to The Electrical Engineer, published Dec. 9, appears to have misinterpreted some of my statements in regard to the nature of the action in the Jacques battery.

Had I stated that the electrical energy of the cell was produced by the conversion of heat into electrical energy, the objection raised by Prof. Anthony to the thermo-electric theory would be applicable. What I stated was that if the current obtained corresponds exactly to the electro-chemical equivalent of the carbon consumed and the carbon dioxide produced, the action is thermo-electric and the oxidation of the carbon is due to the electrolytic action of the thermo-electric current. There is nothing in this statement to imply that the energy of the carbon is, by electrolytic action, converted into heat. On the contrary, the energy of the carbon must, by electrolytic oxidation, as in the electrolytic oxidation of all other substances, be added directly to the energy of the electric circuit without the evolution of any heat and without passing through the form of heat; or, as stated by me, "the energy of the carbon would be consumed in maintaining the electromotive force on closed circuit." On open circuit no carbon would be consumed. C. J. REED.

Philadelphia, Pa.

THAT LONDON "REVIEW" CRITQUE.

I HAVE always admired the quiet way in which The Electrical Engineer goes about its work and attends to business without bothering itself as to criticism from some contemporary or other which thought it had a point to make, showing its smartness. I was glad, however, to see you depart for once from your usual reserve in this respect and administer a well-deserved rebuke to the snobbish and snarling London Electrical Review, whose consciousness of its own superiority is a painful thing to witness. If this attempted criticism on your article had been written by the Review's office boy, I would recommend the discharge of the boy as being unfit for his position, for it seems to me that there must be something gone wrong when a paper so loses its self-respect as to attempt to hold people up to ridicule by mere word quibbling and pure lack of information. In regard to the first item which troubles The Review I will mention for their benefit, and also for the benefit of the blue-covered echo on this side of the water who copied the article, that by referring to any elementary treatise on steam, they will find that the engine is just as much considered a "consumer" of steam as the furnace is a "consumer" of coal. Although this word quibble is hardly worthy of notice I am constrained to quote higher authority, viz.: Haswell's Hand-book, page 724. "In cases of locomotives and portable engines consumption of steam per horse power is" * * *. There are many other references of the same nature. In regard to the other point which the Review finds itself befogged, the writer says: "Considering that the engine drives the dynamo, and not the dynamo, the engine, it is difficult to see where the shock is to come from." This reminds us of the remark of the Irishman, who fell from a building. On being asked if he had been hurt by the fall, he said: "No, sure, it wasn't the fall that hurt me at all. It was the sudden bang agin the earth that nearly done me." In other words, if the man had had the cushioning effect of a spring mattress to fall upon, he would not have been hurt; or, if he had been built larger and stronger, he no doubt would have escaped with a bruise or two.

On the same principle, the success of our modern direct coupling plants is no doubt due largely to the increased size and strength of the engine, so constructed as to withstand the sudden changes of load, such as are daily experienced in railway work wherever there is an electric railway. If the Review's writer still fails to see this point, I would suggest if he will come over here, where there are a few electric railways, I will be glad to show him around, so he can see for himself the point of my remarks.

As to other portions of this attempt to criticise, they are unimportant, with the possible exception of efficiencies, which are too well known to need comment. I would say that while I am quite sure the Review does not pose as a comic paper, you are warranted in saying that the sneer intended to be raised at your expense has resulted as a boomerang on this side of the water, and furnished much amusement to the average American who has noticed the Review's peculiar remarks. R. M.

Brooklyn, N. Y., Dec. 16, 1896.

THE GOVERNMENT BELL SUIT.

There seems to be a great deal of misapprehension in the electrical press regarding the recommendation of Attorney General Harmon, that the "Bell suit" be dropped. Some of your contemporaries are outraged at the impropriety of the Attorney General's attempting to forestall the decision of the Supreme Court in the Berliner case, forgetting apparently that previous to the institution of the Berliner suit, the government brought suit to annul the Bell patents. That was in the days of Attorney General Garland, "Prof." Rogers, and "Pan Electric" telephone. You may remember that the Bell patents expired before the suit to annul them came to final hearing, despite which fact the government went on taking testimony, as I am informed, but apparently to no good purpose, in the opinion of the present Attorney General.

G. D. GATES.

New York, Dec. 18, 1896.

INDUCTION IN NEIGHBORING WIRES.

Can any of your readers give the following information through your journal:

If we have two metallic circuits on same routes, equally and well insulated, what current will be induced into one circuit by the other, considering distance between them to enter into problem:

First: When both circuits are copper. Second: When both circuits are iron. Third: When one circuit is copper and the inducing current is iron. Fourth: When one circuit is iron and the inducing circuit is copper. ROBT. C. MATLOCK.

Springfield, Ill.

SOCIETY AND CLUB NOTES.

THE ROENTGEN RAY BEFORE THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE meeting of the Institute, held on Dec. 16, was devoted to a discussion of the "Roentgen Ray in Its Relation to Physics," and the announcement served to bring out a large attendance of members.

The discussion was opened by Prof. H. A. Rowland, who gave a brief account of the various explanations that had been given as to the source of the Roentgen rays. The first, which was that put forward by Roentgen himself, was that the source was the point where the cathode rays strike. Prof. Rowland had found that it was the anode, and in one of his tubes the radiating spot was only 1-1000th of an inch in diameter. Prof. Rowland then described various experimental tubes which he had made, and found that the rays were most abundant when the cathode rays were focussed on the anode, as in the focus tubes. Prof. Rowland then raised the question whether the rays were still Roentgen rays after they strike an object.

The speaker then passed in review the various physical properties of the ray. He was not positive that the rays were regularly reflected. The magnet does not affect them. Neither could they be prolonged. J. J. Thomson had shown their effect on gases which became conductive under their influence, but the gas loses this power after a short exposure. We were still in doubt as to whether the rays were homogeneous, or whether they were like light rays, which could be broken up into a spectrum. Porter had found that he could make some kinds of X-rays penetrate the bodies better than others.

Regarding the theory of the X-ray in its relation to the ether, Prof. Rowland said that the problem was too complicated for a successful solution in the present state of our knowledge. Experiments he had made showed the rays to have a wave length one-seventh that of yellow light. Others found it to be one-thirtieth; but there was as yet no positive evidence that they were, or were not waves. As to the non-success thus far in reflecting the X-ray, Prof. Rowland thought that this might be due to the fact that the surfaces heretofore employed were too rough. While one theory held the X-rays to be composed of very short waves, another attributed them the waves similar to those of sound; but they were both open to the same objection—namely, that the waves are stopped by the molecule with which they come in contact. According to Maxwell sound waves cannot exist in the ether. He did not believe the impulsion theory put forward by Prof. Stokes to be correct. If it were, any single impulse would be thrown into the shadow, and no such sharp definition as is obtained in Roentgen ray photographs could be had. He also mentioned the vortex ring theory of Prof. Michelson.

In conclusion, Prof. Rowland said that hundreds of years of speculation on the nature of light had not yet enabled us to formulate a comprehensive theory regarding it, and how could one expect the Roentgen ray to be fully explained in less than one year?

Prof. Elihu Thomson did not agree with Prof. Rowland that no X-rays were produced, except when the cathode rays struck the anode. He had insulated a piece of metal in a tube which became the source of the X-rays. He believed that when the cathode rays strike a solid body, such as platinum, and are directed, they produce X-rays; but if they become diffused, no such rays are produced. He had found the various forms of induction coils and static machines to give equally good results, but the static machine to be the most powerful, however. He believed this to be due to the fact that the action of the coil was intermittent, while that of the static machine was continuous; for the same reason he had found the single focus tube better adapted for the static machine, and the double focus tube better with high-frequency alternating coils.

The most effective manner of exciting an X-ray tube Prof. Thomson had found to be one devised by Mr. Herman Lemp. A 12-inch coil was employed and the primary excited by alternating current of 125 cycles. That gave an increased potential in the secondary equal to a 6-inch spark between the terminals. This high potential discharge in the secondary, of course, was an alternating current. He then employed a

break-wheel, so arranged as to pick out the tops of the waves of one direction only, so as to give a unidirectional discharge. The discharges so produced, 125 per second, are wonderfully uniform and their effects most powerful. Unless carefully handled they melt down the platinum in the tube in short order. Thus he had melted a hole through a piece of platinum one-thirty-second inch t..ck in three seconds, and through three-sixteenths inch iron in a high vacuum.

The penetrating powers of the X-rays so produced were also very powerful. The rays penetrated through one-quarter-inch of wrought iron, and he could read the letters of a name plate on an iron casting, nine-sixteenths inch thick, by the aid of the fluoroscope.

Prof. Thomson was also of the opinion that there were varieties of the X-rays. He had found that low vacuum tubes become vigorous when a condenser is placed around the spark gap. He had also tried to ascertain whether the X-rays were diffused or radiated from one body to another, but had obtained negative results.

Coming to the effects of the X-ray on the tissues, Prof. Thomson recounted the experiment he had made on himself by exposing the little finger of his hand to the rays for thirty minutes, described by him in The Electrical Engineer of Nov. 18 and 25. This experiment was carried out with a blue glass tube, having a clear glass window. The effects were very marked, causing the blistering and loss of the skin, and Prof. Thomson, after six and a half weeks, still carried a bandage on the finger. He did not believe the result was due to static effect. He was strengthened in this belief by the fact that a patient, now under treatment in the hospital, had received X-ray "burns" through the clothing. Prof. Thomson also tried to ascertain whether the X-rays would have the effect of causing the falling out of the hair of animals. He subjected a mouse to the influence of the rays, but the experiment was cut short by a cat, to whom the mouse fell a victim.

Prof. M. I. Pupin detailed his experiments on the Roentgen ray, and stated that he had found better effects to be produced when a large amount of energy is sent through the tube at comparatively long time intervals, than a smaller amount at shorter intervals. He also described a method for studying the diffusion and reflection of the rays, and entered into the theory of the subject.

Mr. A. E. Kennelly and Mr. Max Osterberg also discussed the subject briefly.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the last meeting of the Council of the American Institute of Electrical Engineers the following associate members were elected: Charles Hamen Adae, X-ray laboratory, P. O. box 2,809; residence, 36 Thirty-fifth street, New York City. William W. Blunt, electrical engineer, Westinghouse Electrical and Manufacturing Company, Ltd., 32 Victoria street, London, England; Robert A. Byrnes, 98 Ferry street, Lafayette, Ind.; John Jay Crain, electrician's helper, Niagara Falls Power Company, Niagara Falls, N. Y.; Henry H. Humphrey, consulting electrical engineer, Bryan & Humphrey, Turner Building, St. Louis, Mo.; Dr. Erasmus Kittler, Elektrotechnisches Institut, Darmstadt, Germany; Harry Milton Latham, member of engineering staff, Crocker-Wheeler Electric Company, Ampere, N. J.; Robert Stuart Stewart, superintendent of Lines Public Lighting Commission, 440 Jefferson avenue, Detroit, Mich.; Frank Sutton, consulting engineer, 27 Thames street, New York City.

The following institute associate members were transferred to full membership: O. P. Loomis, electrical engineer, Bound Brook, N. J.; A. M. Schoen, electrician, Southeastern Tariff Association, Atlanta, Ga.; H. G. Field, consulting electrical engineer, Detroit, Mich.; S. G. McMeen, engineer, Central Union Telegraph Company, Chicago, Ill.; J. W. McCrosky, electrical engineer, La Capital Tramway Company, Buenos Ayres; S. B. Fortenbaugh, assistant professor of electrical engineering, University of Wisconsin, Madison, Wis.; Lee Hamilton Parker, assistant engineer railway dept. General Electric Company, Schenectady, N. Y.; H. M. Brinckerhoff, electrical engineer, Metropolitan West Side Elevated Railroad, Chicago, Ill.

CHICAGO ELECTRICAL ASSOCIATION.

The Chicago Electrical Association elected officers on Dec. 18, as follows: S. G. McMeen, president; F. S. Hickok, vice-president; E. J. Jenness, treasurer; H. Cochrane, auditor; W. Clyde Jones, G. W. Knox and K. B. Miller, directors; J. R. Cravath (re-elected), secretary and librarian. A paper was read by Mr. Jenness on Decorative Lighting.

OBITUARY.

HARVEY LAMB LUFKIN.

IT is with deep sorrow and regret that we receive the news as we go to press of the death of Mr. H. L. Lufkin, the manager of the Crocker-Wheeler Electric Company, from appendicitis. He had just returned from a long and successful Western trip, and had not yet been home long enough to resume his regular work at the office when he was taken ill and was removed to Mt. Sinai Hospital. An operation was performed, but peritonitis set in and about 10 a. m. on Monday he died quietly. The news comes as a shock to a host of friends in the electrical and other fields.

Mr. Lufkin was still young, having been born in Cleveland, O., in 1857. About fifteen years ago he became interested in electrical matters, and was active in placing a small ozone machine on the market. He became acquainted with Dr. S. S. Wheeler and Prof. F. B. Crocker, at that time beginning the

HARVEY L. LUFKIN.

manufacture of small motors, and was tremendously impressed with the possibilities. He joined them in the C. & C. Motor Company and did some admirable work, far beyond that of the ordinary commercial character. He had a clear mental conception of the problems presenting themselves, and his papers, such as those contributed to the National Electric Light Association, were of the first order of genuine merit and usefulness. In 1892, Mr. Lufkin retired from the C. & C. Co., and rejoined his former associates above mentioned, who had meantime founded with great success the Crocker-Wheeler Electric Co. At that time their product was limited to motors and dynamos not exceeding 5 horse-power, but a recent contract, involving 1,000 horse-power in units of 100 horse-power gives an idea of the growth of the company under Mr. Lufkin's active and intelligent business management. Some of the earliest and largest motor driven plants in this country stand as monuments to his enthusiastic advocacy of the development to which he may be said to have devoted his life.

Mr. Lufkin was a man of most agreeable personality, generous, social instincts, and ready willingness to assist in any object for the welfare of electrical interests. He was one of the leading spirits in the successful Electrical Exposition held in this city last May, and took part in other enterprises and movements of kindred nature. It is needless to say that his services were highly valued by those with whom he had so long been associated, and that the business relation had grown into a close personal friendship, strengthened by the feeling and recollection of early struggles together in promoting the new great industry of electric power.

Mr. Lufkin leaves a widow, to whom the condolence of the entire profession is extended; while it is felt by his old colleagues that they also have sustained an irreparable loss.

DAVID LEONARD BARNES.

David Leonard Barnes, consulting engineer, died in this city on Dec. 15. His name had become well known to the public within the last year as that of the consulting engineer to the Baldwin-Westinghouse combination for building electric locomotives. In the service of those companies, Mr. Barnes designed a set of standard electric locomotives for a variety of

service, and two or three of these locomotives have already been built.

Mr. Barnes was a member of the Am. Soc. of Civ. Engrs., the Am. Soc.. of Mech. Engrs., the Inst. of Civ. Engrs. of London, the Western Soc. of Engrs. and various other scientific and technical bodies. He was a member of the Union League Club of Chicago, the Manufacturers' Club of Philadelphia and the Engineers' Club of New York.

Mr. Barnes was born near Providence, R. I., Aug. 23, 1858, and was educated at Brown University and the Massachusetts Institute of Technology. He had received the degree of master of arts from Brown University. He took special interest in the latest electric railway problems, and contributed to the columns of the Railroad Gazette, The Electrical Engineer, etc., some very valuable articles on the subject.

MR. JOSEPH R. THOMAS.

The death is announced, we regret to say, of Mr. J. R. Thomas, who, since 1883, had been the editor of the well-known technical paper, The American Gas Light Journal. He was a practical gas engineer and manager, and was president of the Society of Gas Lighting in 1875.

Patent Notes.

THE LEONARD SYSTEM OF REGULATION BY SEPARATE E. M. F.

A patent was issued Dec. 8 to Mr. H. Ward Leonard (No. 572,903), covering broadly the use of an independent, positive and controllable electromotive force in the circuit of a motor armature for the purpose of varying the speed of the electric motor. The form of apparatus particularly described in the patents develops an e. m. f. in the motor armature circuit, which is not only variable but also reversible.

While the invention is described in the patent with special reference to its applicability to the control of motors, the patent claims are, in many instances, not limited to motors, but are broad enough to cover the regulation of the e. m. f. upon the terminals of "translating devices" of any kind by the introduction of a positively controllable e. m. f. in the circuit leading to the translating device.

Many of the claims are apparently broad enough to cover such forms of "boosters," now in use, as have a shunt-wound motor driving the "booster" armature, the "booster" armature being in a field which can be regulated at will. The claims of the patent are especially broad, where the e. m. f. of the "booster" armature is so arranged that it cannot only be made to "boost," but also to act counter to the main e. m. f., and thus reduce the e. m. f. at the translating device below that of the source.

There were many claimants for this patent before the Patent Office. In the several inferences, extending over many years, there were such familiar names as Wheeler, Lundell, Hunter, Woods, Wightman, Burke, Bancroft, Blauvelt, etc., indicating a general appreciation of the value of the invention.

This is the last of a series of patents which have been issued to Mr. Leonard on the line of regulation by a separate e. m. f. instead of ohmic resistance, the value of which method he seems to have been first to appreciate clearly.

It is gratifying to learn that this patent is not to be used to force the sale of the apparatus of some particular manufacturer, but will be open to use by anyone under reasonable terms.

Personal.

MR. W. W. LOW, of Chicago, was a visitor to New York last week and was gladly welcomed by a host of friends, who see him here far too seldom.

BENJAMIN FRANKLIN will be the subject of an article by Prof. Treat, of the University of the South, in McClure's Magazine for January. It will be illustrated by fifteen fine portraits, some of which have never before been published.

MR. G. P. LATHROP has begun in the Sunday New York "Press" a very imaginative piece of fiction entitled: "In the Deep of Time." It is based to some extent on notes and suggestions as to new possibilities in invention, furnished by Mr. Edison in a series of conversations.

MR. W. RUTHERFORD, who for some years past has done admirable work as the chief engineer of the Canadian General Electric Company, is about to return to England to take up residence permanently as engineer in charge of the electric railway department to be formed by Dick, Kerr & Co., the great street railway contractors. We regret greatly that a young man of Mr. Rutherford's talent should leave the country, but his going to England is another indication of the coming electric railway régime there, and is for that reason to be hailed as a good sign.

MR. J. D. PARSONS.—The Board of Directors of the Union Traction Company, of Philadelphia, has elected John D. Parsons of Chicago as vice-president and general manager of the company, to take effect at once. Mr. Parsons was vice-president and general manager of the West Side Chicago Street Railway.

MR. GEORGE W. CONOVER has resigned his position as Western manager of the Perkins Electric Switch Manufacturing Company, Hartford, Conn., to take effect Jan. 1, 1897. Mr. Conover, is very well known in electrical circles throughout the West, and although he is not yet ready to announce what his future plans will be, he intends to remain in touch with the interests with which he has been so closely identified for several years past.

MR. J. R. BEETEM has resigned as general manager of the Union Traction Company, of Philadelphia. Mr. Jas. Brocker, once a street car conductor, who has risen by sheer merit, assumes a large part of his duties, in arranging schedules for the running of the cars.

MR. C. D. WYMAN, general manager of the Milwaukee Electric Light and Railway Company, has been elected general manager of the New Orleans Traction Company, under a scheme of reorganization.

Legal Notes.

THE HAITI CABLE NOT ENJOINED.

Judge Lacombe, of the United States Circuit Court, has denied the motion for a preliminary injunction in the suit of the United States against La Compagnie Francaise des Cables Télégraphiques, the United States and Haiti Telegraph and Cable Company and the United States and Haiti Cable Company. The suit was brought to prevent the defendants from laying and landing at Coney Island a telegraphic cable between this country and Haiti, without the consent of the Government, and a motion was made for a preliminary injunction upon a bill of complaint and affidavits.

In his decision Judge Lacombe says:

"The laying of the cable was completed before this motion was submitted, and there is nothing to show that its operation until final hearing will produce irreparable injury to the United States or to any individual. It is thought that without the consent of the General Government, no one, alien or native, has any right to establish a physical connection between the shores of this country, and that of any foreign nation. Such consent may be implied as well as expressed, and whether it shall be granted or refused is a political question, which, in the absence of Congressional action, would seem to fall within the province of the Executive to decide.

"It is further thought that the Executive may effectually enforce its decision without the aid of the courts, and it is certainly indisputable that Congress has absolute authority over the subject. That body is now in session, and if any urgent necessity not disclosed in the papers before the court should call for immediate action, it can settle the question of assent or non-assent with such definiteness as to leave no further room for argument."

CARBORUNDUM LITIGATION.

A suit alleging infringement of the patent on the Cowles electric furnace has been recently brought to an issue by the Cowles Electric Smelting and Aluminum Co., of Lockport, N. Y., and Alonson T. Osburn, trustee, against the Carborundum Company, of Niagara Falls. The argument was begun on Dec. 7 before Judge Joseph Buffington, of the United States District Court. One thousand four hundred pages of expert testimony have been taken since the suit was entered in 1894.

Alfred H. Cowles claims that the electric furnace used was his discovery, and that he had made carborundum in 1885. This he did not know, however, it is claimed, until 1894, when specimens containing carborundum, which had been placed in the Boston Museum, were produced. The entire part of electric furnaces in electro-metallurgy was claimed. The present suit asks for an injunction to prevent the Carborundum Company, which operates under the patents of the well-known inventor, Mr. E. G. Acheson, from

using the furnace. The defense bases its claim on non-interference.

Attorneys George H. Christy and Thomas and William Bakewell represent the defense, and E. N. Dickerson, the New York attorney of the Bell Telephone Company, and C. M. Vorce, of Cleveland, are counsel for the plaintiff.

The Carborundum Company is a Pittsburg concern. It was started at Monongahela City several years ago, but the business grew so rapidly that a larger plant was built last year at Niagara Falls and use was made of the cataract power. Pittsburg capital controls the business, and Andrew W. Mellon and R. B. Mellon, of that city, are principal directors.

ONE CENT'S WORTH OF ANGUISH.

The general rule of law that an action for damages may not be maintained for mental pain and anguish unconnected with or that do not cause physical injury, was followed by Judge Morris in the United States District Court, in Baltimore, on Monday. The action of John R. Treganowan, an artist, against the Western Union Telegraph Company for $5,000 for the "great mental pain and anguish" he was caused to suffer for the failure of the company to deliver a telegram some days before his wife's death, that she was dangerously ill, was taken from the jury, which rendered a verdict, by direction of the Court, for Mr. Treganowan for 1 cent.

TROLLEY CAR SPEED.—APPELLATE DIVISION SUSTAINS AN ORDINANCE OF THE BROOKLYN ALDERMEN.

The Appellate Division of the New York Supreme Court has rendered a decision upholding the validity of the trolley speed ordinance adopted a couple of years ago by the Brooklyn Board of Aldermen. In a test case Civil Justice Neu held one of the trolley companies responsible for violating the ordinance, and imposed a fine of $25, but County Judge Aspinall reversed his decision. The Appellate Court has now sustained Justice Neu.

The ordinance provides for the running of the cars at various rates of speed within the city limits, and it is the intention of the authorities strictly to enforce it. The case will now probably be carried to the Court of Appeals.

ADMISSION OF X-RAY EVIDENCE IN A DENVER MEDICAL SUIT.

In a suit at Denver, for medical malpractice, Judge Le Fevre ruled for the admission of X-ray photographs, and said: "During the last decade, at least, no science has made such mighty strides forward as surgery. It is eminently a scientific profession, alike interesting to the learned and unlearned. It makes use of all science and learning. It has thus been of inestimable service to mankind. It must not be said of the law that it is so wedded to precedent that it will not lend a helping hand. Rather let the courts throw open the door to all well-considered scientific discoveries. Modern science has made it possible to look beneath the tissues of the human body, and has aided surgery in telling of the hidden mysteries. We believe it to be our duty in this case to be the first, if you please to so consider it, in admitting in evidence a process known and acknowledged as a determinate science. It may solve a present condition. The exhibits will be admitted in evidence."

FIGHTING THREE-CENT CAR FARES IN CHICAGO.

An ordinance calling for a four-cent fare on all the street car lines in Chicago has passed the City Council. The vote was overwhelmingly in favor of the ordinance. In case the Mayor vetoes the ordinance it is said it will be passed over it by the Council. There were many who favored a three-cent fare. The street car companies will fight the ordinance, and their lawyers are already working to that end.

DUTIES OF STREET CAR CONDUCTORS.

The Superior Court, at New Haven, Conn., on Nov. 10, in a suit for damages, gave a decision, holding that except in exceptional conditions of danger a conductor is not bound to assist a passenger in alighting from a street car.

RAILWAY LINE DETAIL LITIGATION.

The General Electric Company has just brought five suits against the Fiberite Company, of Mechanicville, N. Y., manufacturers of the Medbery Insulation and Overhead trolley Equipment, for alleged infringement of patents owned by them, on "suspension devices and ears" for trolley roads. These suits will be watched with much interest, by all electric roads not using G. E. equipment, and by all manufacturers of overhead devices. The Fiberite Company propose to defend this suit vigorously.

NEWS AND NOTES.

MOTOR NAME PLATES.

It is worth pointing out that according to Rule 8, Section F, of the New York City Fire Department, motors must have the speed, voltage, and amperes, or the normal capacity in horsepower, stamped in plain figures, on the iron work of each motor, where they can be readily seen. This would seem to bar out name plates, the object being to prevent deception which might lead to overheating a motor.

MR. TESLA ON THERMO ELECTRICITY.

In a letter to the editor of the Buffalo Enquirer, Mr. Nikola Tesla replies as follows in regard to an inquiry on the subject of the future of electricity:

"The transmission of power has interested me not only as a technical problem, but far more in its bearing upon the welfare of mankind. In this sense I have expressed myself in a lecture, delivered some time ago.

"Since electrical transmission of energy is a process much more economical than any other we know of, it necessarily must play an important part in the future, no matter how the primary energy is derived from the sun. Of all the ways the utilization of a waterfall seems to be the simplest and least wasteful. Even if we could, by combining carbon in a battery, convert the work of the chemical combination into electrical energy with very high economy, such mode of obtaining power would, in my opinion, be no more than a mere makeshift, bound to be replaced sooner or later by a more perfect method, which implies no consumption of any material whatever.

NEW RAILS FOR THE B. & O. S. W.

The Baltimore and Ohio Southwestern Railroad has made a contract with Carnegie & Co. for 7000 tons of steel rails, 75 pounds to the yard, for immediate delivery. The rails will cost somewhere in the neighborhood of $200,000 and will be delivered about the first of December.

X-RAYS HELP TO RELIEVE SUFFERING.

Many people have applied recently to Supt. Meadowcroft, of the Edison Lamp Works, Harrison, N. J., to locate splinters, needles, etc., in their hands and feet. On two occasions he has done so by means of the X-rays, having a plant of that kind in the factory. Mrs. Margaret Englemyer, a dressmaker, had a broken needle in her left thumb, and went to the works recently. The position of the needle was located by the X-rays, and it was removed.

THE NEW PLAY "THE ELECTRICIAN.

We are in receipt of the subjoined item as to the new play of Mr. C. E. Blaney, called "The Electrician":

"Rehearsals for 'The Electrician' will be called about January 1, and Chas. E. Blaney and Manager Crossley are busy arranging for this mammoth production. The scenic and electrical effects are the most elaborate that have been attempted in years. The first act, showing a banking house in Denver during the busy hours, is the most complete as to scenery and details that has ever been put on any stage. Act second, with its large dynamos actually running by steam and generating electricity and lighting the stage and city in the distance, is one of, if not the most, realistic scenes ever offered the public in a dramatic production. The killing of the inventor by the villain pushing him upon a live wire, and the fall of a lineman from the top of a pole, after receiving a shock, are realistic and perfectly consistent with the natural action of the piece. The Palace Hotel, Cripple Creek, scene in act third, introduces an entirely new type of characters and surroundings. Rough miners, gamblers and typical Westerners, are all making merry on Christmas Eve, with the tenderfeet from the East, while Nell, the belle of Cripple Creek, sings and dances for their amusement. Act fourth shows the ball room and parlors of the ——— Hotel, Denver, during a reception given by Edwin Palmer, the Gold King, to his friends. The finish of this act, contrary to the usual fourth act finish, is one of unusual interest, as the villains are discovered dead behind a screen, where they were scheming for the destruction of the hero—the victims of their own plot"

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED DECEMBER 15, 1896.

Alarms and Signals:—

INDICATOR OR SIGNAL. J. P. Coleman, Swissvale, Pa. 573,207. Filed June 29, 1896.

A case supporting bars having one end secured in the case, sleeves adapted to fit over the bars, and signal operating mechanism supported by the sleeves.

ELECTRIC SIGNALING APPARATUS. F. B. Herzog and S. S. Wheeler, New York, 573,221. Filed Jan. 25, 1896.

Comprises two or more separately variable transmitting mechanisms, each including a motor, together with shifting devices.

Conductors, Conduits and Insulators;—

INSULATOR. F. M. Locke, Victor, N. Y., 573,092. Filed Aug. 24, 1896.

An insulator comprising two members, the outer one composed of insulating material puncturable by an electric current, and an inner member of less puncturable insulating material.

WALL INSULATOR. J. J. O'Neill, Boston, Mass., 573,101. Filed Dec 19, 1895.

Consists of a tapering member provided with a lug forming a stop, and a hooked insulated member extended from the tapering member intermediate at its ends.

ELECTRIC CABLE. F. Borel, Cortaillod, Switzerland, 573,176. Filed Jan. 7, 1896.

Consists of a conductor of copper, and intervening asbestos forming the insulating material.

AUTOMATIC GROUNDING DEVICE FOR ELECTRIC CONDUCTORS. G. A. Jewett, Chicago, Ill., 573,222. Filed Dec. 6, 1895.

In connection with a conductor a contact device normally open, but arranged to be closed by gravity in case of breakage of the conductor.

CONDUCTOR OF ELECTRICITY AND CONDUIT FOR HOLDING SAME. A. Selkirk, Albany, N. Y., 573,302. Filed Jan. 30, 1896.

Details of construction.

WIRE JOINT. C. E. Brown, Chicago, Ill., 573,386. Filed Oct. 11, 1895.

Consists of a sheet of metal foil rolled so as to form two rolls, without the use of solder or brazing that will completely cover the wires at the joint.

Dynamos and Motors:—

DIRECT CURRENT DYNAMO ELECTRIC GENERATOR. B. G. Lamme, Pittsburg, Pa., 573,009. Filed March 11, 1896.

A parallel-wound armature for multipolar direct current machines provided with alternating current connections between points in its winding of normally equal potential through which leading and lagging currents may be transmitted to equalize the magnetic circuits of the machine.

COLLECTING BRUSH. E. B. Raymond, Schenectady, N. Y., 573,105. Filed Aug. 5, 1896.

Composed of a core of conducting material surrounded by insulation.

SECURING FIELD MAGNET POLES. H. G. Reist, Schenectady, N. Y., 573,107. Filed Aug. 24, 1896.

The pole pieces are composed of laminated material and are dovetailed into the periphery of the revolving structure.

ATTACHING FIELD MAGNET POLES. F. O. Blackwell, Schenectady, N. Y., 573,130. Filed Aug. 24, 1896.

Similar to above.

Electric Furnaces and Heating:—

ELECTRIC FURNACE. M. Schindler, Neuhausen, Switzerland, 573,041. Filed Aril 23, 1896.

Means for cooling the electrode holders, and the electrodes.

ELECTRIC BOILING APPARATUS. J. W. Schindler-Jenny, Kennelbach, Austria-Hungary, 573,042. Filed Feb. 27, 1894.

Consists of a water tight hollow body in which electric conductors are enclosed between rings or discs of non-conducting fireproof material.

ELECTRIC SOLDERING CLUB. P. Stotz, Stuttgart, Germany, and F. W. Schindler-Jenny, Kennelbach, Austria-Hungary, 573,245. Filed Jan. 14, 1895.

Details of construction.

Electro-Metallurgy:—

PROCESS OF PRECIPITATING PRECIOUS METALS FROM THEIR ALKALI CYANIDE SOLUTIONS. M. Netto, Almazarron, Spain, 573,233. Filed March 16, 1896.

Consists in acidulating the alkali cyanide solution containing the metals by hydrochloric acid so as to precipitate silver chloride, separating the precipitated silver chloride by filtration from the solution, and subjecting the acid filtrate to the action of an electric current so as to deposit the gold on the cathode.

Lamps and Appurtenances:—

ELECTRIC SIGN. F. H. Hawkins, New York, 573,088. Filed Jan. 13, 1896.

Comprises a vacuum chamber having two transparent faces and also having a longitudinal central partition wall, filaments of carbon arranged in said chamber on opposite sides of the partition wall and shaped to form a letter, and conductors connected to the filaments.

ELECTRIC ARC LAMP. C. Richter and R. T. Eschler, Camden, N. J., 573,161. Filed March 26, 1896.

Comprises a cup and arc inclosing chamber, and a coiled spring, the latter being reeved in the cup, and engaging the chamber to yieldingly support it.

ELECTRIC ARC LAMP. C. Richter and R. T. Eschler, Camden, N. J., 573,162. Filed April 9, 1896.

Consists of an electric arc lamp of the clutch type, in which the brass carbon rod is dispensed with.

COMBINATION GAS AND ELECTRIC FIXTURE. J. E. & W. M. Brown, Toledo, Ohio, 573,387. Filed July 2, 1896.

Combines a service pipe, a fixture suspended and supported by means independent of the service pipe, and an insulated coupling interposed between fixture and service pipe.

HEADLIGHT FOR ELECTRIC CARS. J. H. Neal, Boston, Mass., 573,283. Filed July 10, 1895.

The front of the headlight is substantially flush with the dashboard.

ELECTRIC ARC LAMP. A. C. Dobrick, Chicago, Ill., 573,398. Filed June 13, 1896.

Clutch for holding carbon.

Measurement:

ELECTRIC METER. W. D. Marks, Philadelphia, Pa., 573, 021. Filed Oct. 20, 1896.

Comprises a controlling amperemeter and means for automatically tapping the amperemeter.

WATTMETER. T. Duncan, Ft. Wayne, Ind., 573,078. Filed April 29, 1896.

Comprises an armature and a field magnet, a shunt core arranged with one end intersecting the axis of the field magnet, and a shunt coil wound upon the opposite end only of the core.

METER FOR MEASURING ELECTRIC CURRENTS. T. Duncan, Ft. Wayne, Ind., 573,079. Filed May 7, 1896.

The combination with the meter sindle, of a multiolar permanent magnet having radiating limbs, and a fixed paramagnetic ring surrounding the outsetting poles of the magnet in close proximity thereto.

ELECTRIC METER. T. Duncan, Ft. Wayne, Ind., 573,080. Filed July 2, 1896.

Consists of a disc armature comprising a plurality of segment-wound coils lying flatwise in the disc with their arcs toward the periphery, in combination with segment-wound series coils laid parallel with the plane of the disc with their arcs overlying the arcs of the armature coils.

ELECTRIC METER. C. Erben, Berlin, Germany, 573,082. Filed Oct. 10, 1895.

Employs an oscillatory balance spring of a clockwork with a counter spring connected to its outer end magnets, and means for causing the magnets to control the arc of oscillation of such counter spring.

Miscellaneous:

RESONATOR FOR PIANOS. F. L. Goulvin, Valence, France, 572,981. Filed April 30, 1894.

Adapted to serve as receivers to convey sounds to the ears of persons at a distance from the piano, in the manner of a telephone.

THERMOSTAT. C. Burgher, Newton, Mass., 573,134. Filed Aug. 8, 1896.

The operative parts are protected by a casing arranged to permit of the free circulation of air.

METHOD OF AND MEANS FOR REMOVING PARAFFIN FROM OIL WELLS. F. A. Flanegin, Washington, D. C., 573,142. Filed April 7, 1896.

Consists of a heater provided with a surrounding casing having a contracted upper end and forming a chamber between the heater and the casing in which a paraffin solvent is heated.

PROCESS OF PURIFYING AND DECOLORIZING SACCHARINE OR OTHER LIQUIDS. M. Pridham, Philadelphia, Pa., 573,289. Filed Sept. 10, 1896.

Consists in subjecting the liquid to the direct action of an electric current and simultaneously passing ozone gas through the liquid.

PROCESS OF PURIFYING AND DECOLORIZING SACCHARINE OR OTHER LIQUIDS, 573,290. Filed Sept. 10, 1896.

Similar to above.

APPARATUS FOR PURIFYING AND DECOLORIZING SACCHARINE OR OTHER LIQUIDS. M. Pridham, Philadelphia, Pa., 573,355. Filed Sept. 12, 1896.

Consists of a tank, electrodes, and collecting racks for collecting the impurities precipitated.

SELF WINDING MECHANISM FOR ELECTRIC CLOCKS. C. M. Crook, Elgin, Ill., 573,430. Filed April 20, 1896.

Details of construction.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. B. E. Osborn, Auburn, N. Y., 573, 033. Filed April 10, 1896.

Sectional conduit system.

ELECTRIC RAILWAY CONSTRUCTION. G. Westinghouse, Pittsburg, Pa., 573,066. Filed June 8, 1896.

A structure for surface contact electric railways, comprising a switch box, a beam provided with contact supporting devices and extending laterally from the switch box beneath both track rails, and means for clamping both the switch box and the beam to the track rails.

SWITCH. E. M. Hewlett, Schenectady, N. Y., 563,146. Filed July 16, 1896.

Magnetic switch for closed conduit electric railways.

ELECTRIC RAILWAY. A. Sprague, San Leandro, Cal., 573,169. Filed March 30, 1896.

Employs a channeled insulated surface rail having a conductor fixed to it with a pivotally secured lever having a trolley to engage the conductor.

ELECTRIC RAILWAY. A. C. O'Connor, Lynn, Mass., 573, 234. Filed Oct. 26, 1895.

Comprises two or more separably variable transmitting mechanisms, each including a motor, together with shifting devices.

TROLLEY POLE SAFETY DEVICE. B. H. Borrenson, Minneapolis, Minn. 573,257. Filed July 26, 1895.

Mechanism for lowering the pole when out of contact with the conductor.

SWITCH FOR ELECTRIC RAILWAYS. S. A. Mustain, Rincon, New Mexico, 573,344. Filed June 22, 1896.

Operated by current from the trolley wire.

STATION INDICATOR FOR RAILWAYS. A. Palfy, Buda-Pesth, Austria-Hungary, 573,350. Filed Aug. 3, 1896.

An electrically operated disc on which the names of the stations are displayed, and an alarm bell to sound when each change has been effected.

Telegraphs:—

MECHANICAL TELEGRAPH-SOUNDER. W. W. Alexander, Kansas Cty, Mo., and M. C. Gilliham, Kansas City, Kansas, 572,945. Filed April 23, 1894.

Operates without a local battery.

RECEIVER FOR SUBMARINE TELEGRAPHS. A. Piedfort, Paris, France, 573,286. Filed Dec. 19, 1895.

Mechanism for tracing on paper the signs corresponding to the direction of the current.

Telephones:—

TALKING MACHINE APPARATUS. E. H. Amet, Waukegan, Ill., 573,071. Filed Sept. 21, 1894.

The talking machine is located at the central station and is heard at substations by means of a controlled telephone circuit.

TELEPHONE CIRCUIT LINE SIGNAL. T. C. Wales, Jr., and C. H. Arnold, Boston, Mass., 573,117. Filed July 20, 1896.

Comprises a call signal, a signaling current generator furnishing current therefor, a secondary line signal in a local circuit, and a polarized electromagnetic device in inductive relation with the circuit of the generator controlling the secondary signal.

TELEPHONE TRANSMITTER. F. A. Ray, Boston, Mass., 573,294. Filed April 6, 1896.

Comprises a diaphragm consisting of two members, a fixed member, a vibrating disc contiguous to the fixed member, and a plurality of flexible supports which interconnect the two members.

TELEPHONE TRANSMITTER. L. W. Pullen, Camden, N. J., 573,356. Filed Nov. 11, 1895.

Consists of two or more opposing electrodes yieldingly connected together in such a manner as to form a cavity or chamber between them, and an insulating ring extending into the chamber between the electrodes.

Trade Notes and Novelties

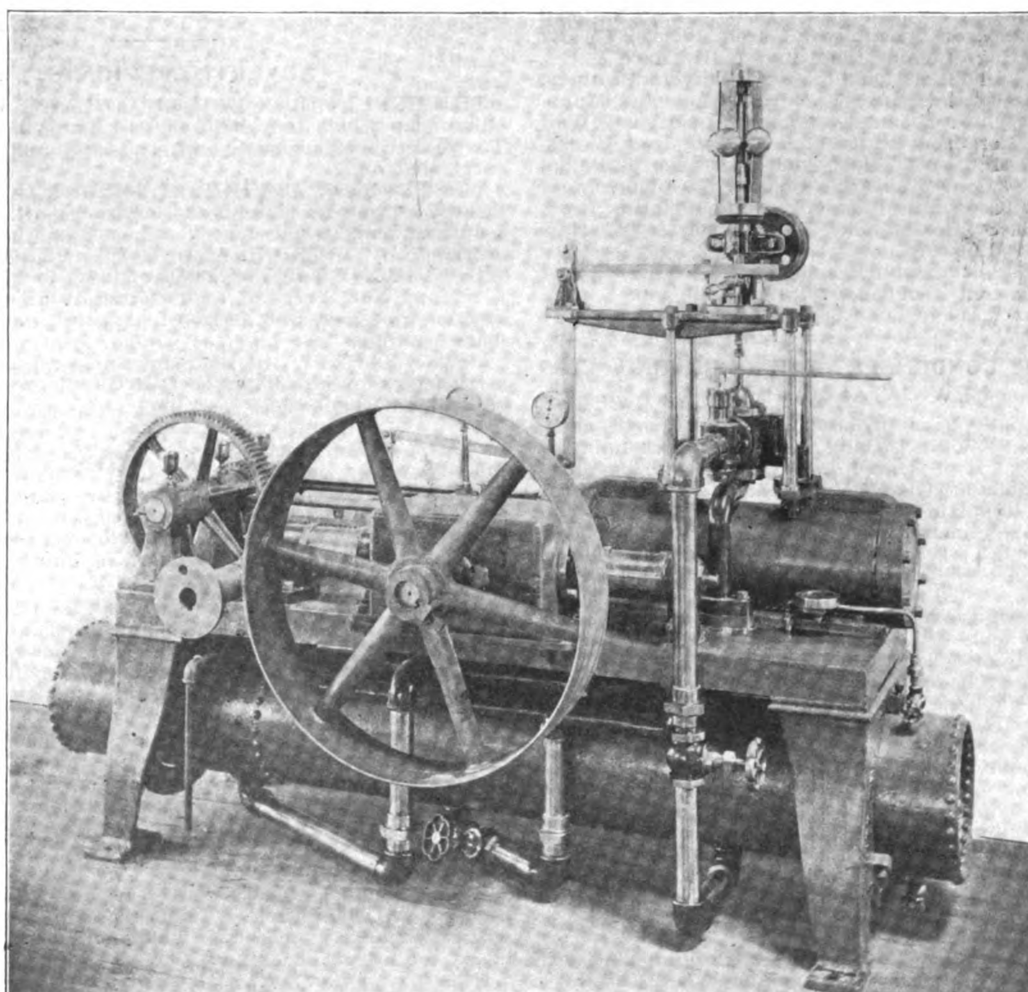
AND MECHANICAL DEPARTMENT.

LOMBARD WATER WHEEL GOVERNORS.

The regulation of water wheels driving electric generators has always been a serious problem with which hydraulic engineers have had to contend, but it would seem that regulation can now be had comparable with that obtained with the automatic steam engine.

This close regulation has been accomplished in the Lombard water wheel governor which was selected and installed in the magnificent, up-to-date power house of the Bridge Mill Power Company, at Pawtucket, R. I., which is illustrated elsewhere in this issue. The Lombard Water Wheel Governor Company, of 61 Hampshire street (Roxbury), Boston, Mass., claim that since they have been in business they have never failed to govern water wheels operating electric street railway generators (the most difficult load to govern), to the entire satisfaction of the purchaser. The company's governors are now being used successfully with every modern make of turbine, working under heads varying from 6 to 200 feet.

The accompanying engraving represents the type C, Lombard water wheel governor installed in the Bridge Mill plant.



LOMBARD WATER WHEEL GOVERNOR, TYPE C, BRIDGE MILL POWER PLANT.

RODNEY HUNT TURBINES AND LOMBARD GOVERNORS.

The Rodney Hunt Machine Company, of 70 Kilby street, Boston, are installing a plant, consisting of eight pair of wheels similar to those now running in the Bridge Mill Power plant at Pawtucket, R. I., described elsewhere in this issue. These wheels will be placed in the plant of the Columbia Water Company, at Columbia, S. C., and will develop 11,000 horse power. As in the case of the Pawtucket plant, the wheels will be equipped with Lombard governors, manufactured by the Lombard Water Wheel Governor Company, of 61 Hampshire street (Roxbury) ,Boston, Mass.

PHILLIPS' INSULATED WIRE.

We have received from the Phillips Insulated Wire Co., of Pawtucket, R. I., the new price list and samples of their fire and weather-proof wire, underwriter's wire and "Ideal" wire, all of which they are making in connection with their celebrated "O. K." weather-proof wire. The Ideal wire is specially worthy among this class of conductors. It has a black insulation with white fireproof outside finish, adapted for exposed wiring when a good white finish is desired. The prices also are very attractive and with the probable early to be looked for rise in copper, intending purchasers would do well to communicate promptly with the Phillips Company.

TORRINGTON, CONN.—The Hendey Machine Company have adopted the Eddy system for lighting and power transmission in their new shop.

THE PURITAN ELECTRIC CO.

The inclosed arc lamp has made wonderful strides during the last two years, but thus far it has been used only in connection with direct current circuits. When one considers the large preponderance of alternating current stations in the United States, it must be evident that a still greater usefulness awaits the enclosed arc lamp on alternating circuits. To meet this demand the recently organized Puritan Electric Company, of 150 Nassau street, New York, and 178 Devonshire street, Boston, Mass., have brought out an alternating enclosed arc lamp, possessing a number of striking features. Thus, the lamp will burn equally well on circuits of 7,200 or 16,000 alternations, while at the same time it can be run on continuous current circuits without change of adjustment. The burning of the lamp is very steady, and the feed is imperceptible. The lamp is also practically inaudible in operation. The lamp is 33 inches long and burns 10 hours. Mr. Stuart W. Wise, formerly with the Manhattan General Construction Company, is the president and general manager of the company.

KENT'S LUBRICATING COMPOUND.

This compound, which has come into successful use, is constantly increasing in popularity. Owing to its peculiar composition it adheres to the bearing surface, where it is needed, instead of flowing away from it. Every particle of it is a lubricant, but the mixture is so happily chosen that they blend perfectly to form a homogenous and stable compound.

Among the hundreds of users of Kent's compound we may mention the following: Consolidated Gas Company, National Saw Company, Jackson Architectural Iron Works, De La Vergne Refrigerating Machine Company, L. H. Mace & Co., Interior Conduit and Insulation Company, Travers Brothers, Louis Bossert, Bronx Company, T. New Roofing and Manufacturing Company, F. E. James Company, National Wall Paper Company, Ferguson Brothers, J. L. Mott Iron Works, Edwards & Co., Methodist Book Concern, Judge Building, Quintard Iron Works, George Fox's Sons, J. E. Linde Paper Company, Central Cooperage Company, Potter Printing Press Company, Hudson Steam Laundry, Baumgarten & Co., Harper Brothers.

Kent's lubricating compound is sold by the New York and New Jersey Lubricant Company, 30 Cortlandt street, New York.

THE WHEELER CONDENSER & ENGINEERING CO'S NEW CATALOGUE.

The above company have just issued a very artistic catalogue of the Barnard Water Cooling Tower, of which they are the manufacturers. It is printed on heavy calendered paper, well illustrated and describes the system in its application and adaptability to steam and refrigerating plants.

Of late years the constructing engineer has been afforded opportunity to install the most improved appliances with continued gain of economy. Condensing apparatus, where water is available for it, is now regarded a necessity, in so much as to often cause the location of a plant at a remote point to meet this end. It is under just such conditions that the Barnard system demonstrates its value as by it any engine or unit of power may be operated, condensing with a high degree of vacuum. The purified distilled water is very desirable for boiler feed supply, as no scale is formed in the boilers and the consequent loss in fuel and labor is eliminated. In cities, where the yard room for the cooling tower cannot be had, the roof of the building or other elevation may be utilized.

The Wheeler Company make a specialty of surface condensers, heaters, filters and evaporators, publishing separate catalogues of them, which may be obtained by addressing them at their new offices, 120-122 Liberty street, New York.

METROPOLITAN ELECTRIC CO.

The catalogue of the Metropolitan Electric Company, of Chicago, contains 755 large-sized pages, and over 2,250 illustrations, covering practically everything in the electric line, with a large amount of information on the various articles illustrated. In fact, the catalogue is, in reality, an encyclopædia of electricity, and is used very largely for reference by engineers, electricians, colleges and institutions where electricity is studied. The book is handsomely gotten up, well bound and printed on fine paper, and is a valuable addition to any collection of books on electricity, as well as to the reference books necessary to any purchasing agent.

J. B. COLT & CO., 115 Nassau street, New York, have removed their St. Louis office to 517 Olive street.

NEW MANAGER FOR THE C. & C. ELECTRIC CO.

The C. & C. Electric Company have appointed Mr. D. W. Barnes as general manager of their business, with headquarters in their general offices, at 143 Liberty street, New York. Mr. Barnes has been associated with the C. & C. Company since 1890, having for the past year filled the position of chief engineer in entire charge of the company's works at Garwood, N. J. Previous to that time he had charge of the mechanical design at the works. Mr. Barnes thus brings with him to the management of the company's affairs a thorough and practical knowledge of all branches of the business. He is thoroughly versed in the matter of successful manufacturing, as well as engineering, and intends to push the company's business, especially in the field of electric power and isolated plants.

A BIG ST. LOUIS ELECTRIC COMPANY.

The St. Louis Electric and Construction Company has filed articles of incorporation. It has a fully paid capital stock of $600,000. The incorporators holding one share each are as follows: Ellis Wainwright, Charles H. Turner, Geo. J. Kobusch, Philip Stock, L. B. Pierce, Rolla Wells, Breckinridge Jones, Julius J. Walsh, Adolphus Busch, C. K. D. Walsh, Wm. T. Haarstich, Otto Von Echrader, C. Marquard Foster, Henry Nicholas, August Gehner, Hopkins H. Crawford, Wm. C. Orthwein, Wm. F. Walker and H. S. Priest. The remaining shares, 5,980, are held by James H. Parish. The company proposes to do a business both in electric lighting and in telephony.

ADVERTISERS' HINTS.

THE BERLIN IRON BRIDGE COMPANY illustrate a machine shop which they built for the Titusville (Pa.) Iron Co. The roof trusses are made entirely of iron and are designed to carry shafting.

WESTINGHOUSE, CHURCH, KERR & CO. have recently installed the steam plant of the Pawtucket (R. I.) Electric Co., a description of which may be found on another page.

THE INDIA RUBBER AND GUTTA PERCHA INSULATING COMPANY will take the opportunity to wish their friends a "Happy New Year" at their Cortlandt street offices on the afternoon of Dec. 31st. Drop in and see them—you will be made welcome.

HEINE SAFETY BOILERS for the steam generating plant at the works of the Pawtucket (R. I.) Electric Company, are described in this issue.

NEW YORK NOTES.

A POCKET CALENDAR printed on celluloid and covering the entire year of 1897, is furnished by the Fuel Economizer Co., of Matteawan, N. Y. It is a very convenient thing and for real usefulness is not surpassed by anything we have yet seen for next year.

THE ELECTRIC PROTECTION CO., of Philadelphia, have issued a notice to the trade of important changes in quotations of their Stevens flush switches. They also state that hereafter Mr. C. D. Shain will be their sales agent for the States of New York, Connecticut and New Jersey north of Trenton.

FRED M. LOCKE, Victor, N. Y., in furnishing his high-grade triple petticoat insulators, made them of Imperial porcelain, which stood the severe test for the Niagara Falls-Buffalo transmission line, to which they were subjected. The insulators stood the test nobly, where other grades of porcelain had failed.

THE GARVIN MACHINE COMPANY, New York, have issued a pocket map of New York City and vicinity within a radius of 16 miles, and a detailed map of New York City on the reverse. The whole is inclosed in a pasteboard cover, with a space for memoranda, which contains a little advertising of the Garvin machinery.

JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., have just issued a neat little pamphlet, prettily covered, illustrative of their various graphite productions for use in a wonderfully wide range of industries. All their manufactures are standard and popular, and are set forth in this book with surprising fullness of illustration and detail.

NIAGARA-BUFFALO.—Reports from Niagara go to show that the power transmission to Buffalo is working very successfully. The trouble with the insulators has been eliminated since the exclusive use on the line of the "Niagara" insulators made by the Imperial Porcelain works of Trenton, N. J., to which descriptive references have already been made in our pages.

ACTIVITY OF THE AMERICAN ENGINE CO.

We have received from the American Engine Company, Bound Brook, N. J., the following list of their apparatus supplied during November: 18 kilowatt dynamo, Syracuse "Post," Syracuse, N. Y.; 50 kilowatt dynamo, "Evening Star," Washington, D. C.; 25 horse-power motor, Springfield "Union," Springfield, Mass.; 12 horse-power motor, New York "Tribune;" 12 horse-power motor, Peoria "Herald," Peoria, Ill.; 12 horse-power motor, Duluth "News Tribune;" 1 8x8 inch engine, Leavenworth "Times," Leavenworth, Kan.; 5 horse-power motor, St. Paul "Pioneer Press;" 10x10 inch engine and 50 horse-power boiler, Chinese Government; 25 kilowatt dynamo, the "Morning News," Savannah, Ga.; 5 horse-power motor, Salem "Daily Gazette," Salem, Mass.; 12 horse-power motor, Chicago "Journal;" 50 horse-power motor, Boston "Daily Post;" 75 kilowatt dynamo, Kansas City "Star;" 12 horse-power motor, W. D. Boyce & Co., Chicago, Ill.; 14x12 inch engine, J. Harper Bonnell Co., Long Island City, L. I.

NEW YORK NOTES.

SUBMARINE CABLE making and laying will be the subject of a special article in McClure's Magazine for January. It will be illustrated.

T. J. MURPHY & CO., the manufacturers of electrical supplies, have made an assignment to F. Hulse, with a preference of $1,597 to the Eureka Tempered Copper Co. The total liabilities are $7,000.

KENSINGTON ENGINE WORKS.—We are informed that the Kensington Engine Works, Ltd., whose main office and works are at Philadelphia, Pa., have opened a branch office at 74 Cortlandt street, New York City.

C. F. CROSELMIRE & SON, 251-255 New Jersey Railroad avenue, Newark, N. J., are large manufacturers of platinum wire, the raw stock of which they import direct from Russian mines and refine at their works. Their business was established in 1875 and is known throughtout the electrical and other fields.

DALE MANUFACTURING COMPANY, Greenwich street, New York City, report that they are very busy on their various lines of trade, and that the outlook for the new year is excellent. They will be glad to entertain inquiries for electrical specialties of all kinds, particularly those to which they devote attention.

THE GARVIN MACHINE COMPANY, Spring and Varick streets, New York City, have a splendid new building run by electric power and are turning out some fine goods. Their new little brochure of bicycle machinery is a revelation as to the special tools they make for that line of trade, and shows much ingenuity and large resources.

A. O. SCHOONMAKER.—In order to meet the increasing demand from his Western trade, A. O. Schoonmaker, of 158 William street, has opened an office at 1563 Monadnock Building, Chicago, where he will be represented by Mr. John Child, who will carry a full line of his well-known India and amber mica and be prepared to fill all orders promptly.

BACKUS WATER MOTOR COMPANY, 174 Pennsylvania avenue, Newark, report business good and prospects very bright for the sale of their gas engines. They recently installed a 20 horse-power gas engine for driving an electric plant in Pittsburg, in which city they also obtained an order from Bair & Gazzam Company for two 20 horse-power and one 12 horse-power engine.

THE WILSON & WINKLER CO., 779 Greenwich street, New York, have just completed a large wiring contract for the Claus Lipsius Brewery, Brooklyn. Both Messrs. Wilson & Winkler are practical men, having had thorough experience for many years in the works of the General Electric Co., Schenectady. This firm build and refill commutators, do general construction and switchboard work, and deal also in engine and dynamo supplies.

THE LINK BELT ENGINEERING COMPANY, of Nicetown, Philadelphia, and 49 Dey street, have issued a most valuable and interesting book of 130 pages devoted to modern methods in elevating and conveying materials and in the transmission of power. There are many points of value to electric lighting and street railway men, and copies of the book will be gladly sent to them by the enterprising publishers, on application.

MR. M. R. RODRIGUES, of 19 Whipple street, Brooklyn, N. Y., reports that in one day's mail recently he received orders for fifty medical batteries and 250 of his celebrated "Baby" motors. Among the new apparatus he is placing on the market is a small medical battery 6½x3¼ of great strength, which will retail at a low price. This battery has been tested, and has given excellent results, the strength of the current being something almost phenomenal. The factory is working late nights to keep up with the orders already on hand.

THE GLENS FALLS PAPER MILLS COMPANY, of Glens Falls, N. Y., are making extensive improvements in their various plants and have placed an order with the Berlin Iron Bridge Company, of East Berlin, Conn., for a new pulp mill, at Cadyville, N. Y., including water tower and boiler house. They have also placed an order with the Berlin Iron Bridge Company for additional buildings for their Kent's Falls plant, consisting of a pulp mill, boiler house, barker room, and wood room. The contract is a large one. Orders for machinery for equipping the various buildings will be placed at once.

THORPE, PLATT & CO., Fidelity Building, Cedar street, New York, are placing on the market the Geipel patent steam trap, which will be sent on approval. It is said to have met with extraordinary success in Europe and is used by the British Admiralty for high pressure steam as well as in public buildings, where heating with exhaust steam is employed. The form in which the expansion parts are arranged, viz., that of an isosceles triangle, causes a large motion to be imparted to the apex for very small changes in the length of these parts. It will work on widest variations of pressure and will discharge against a head.

THE IMPERIAL ELECTRIC COMPANY, 140 Washington street, New York, report their factory very busy on a large variety of work. This company manufactures electrical specialties of every description for outside firms under contract. Their excellently equipped factory is under the personal supervision of thoroughly experienced and practical men. Mr. J. W. Eskholme is vice-president and general manager, and Mr. H. J. Linder, secretary and treasurer. The Imperial Electric Company manufacture slow-speed dynamos and motors, electrical and hardware sundries, aside from which they do experimental work, designing and repairs.

WESTERN NOTES.

CICERO, ILL., was to have had incandescents for street lighting, but the committee has now decided to reject all such bids and to advertise only for arc lights.

THE MICHIGAN PIPE COMPANY have, we regret to learn, suffered severely from a fire at their plant, Bay City, Mich. The loss is put at about $100,000; the insurance is $35,000.

PRESIDENT J. E. KEELYN, of the Western Telephone Construction Company, has been in the South planning for an extensive system of independent service, running from Norfolk, Va., across to Cincinnati.

The CONNECTICUT TELEPHONE AND ELECTRIC CO., Meriden, Conn., have issued a very pretty and tasteful calendar illustrative of the idea that beauty when unadorned looks best. It will attract attention wherever hung.

CEDAR RAPIDS, IOWA.—The "Independent" Telephone Company has already reached its limit of 500 subscribers, and has had to put in another section for 100 additional numbers, in its exchange. It has also ordered 5,000 feet of cable. The apparatus of the American Electric Telephone Company, of Kokomo, Ind., is used.

THE ELECTRICAL APPLIANCE CO. report that their Armorite interior conduit is meeting with a rapid sale. The great advantage in being able to bend the conduit, and thus avoid the use of regular and special elbows, is very much appreciated by the trade. The saving in time required for installing is also a point that is not overlooked.

H.-S.-G., standing for "Honest-Standard-Gold," also stands for the trade-mark of Houston, Stanwood & Gamble, engine builders of Cincinnati, O. A golden yellow card just issued by that firm tells the reader that he can know more about high grade substantial steam engines by addressing the firm and asking for the latest edition of their Ready Reference Book.

GREELEY, COLO.—At a meeting of the City Council, held Dec. 15, the Committee on Electric Lighting was instructed to look up the matter of placing a lighting plant, to be run in connection with the city water plant, so that the city can supply itself with its own street illumination. Mr. D. F. Camp, City Marshal, can be addressed. Mr. M. F. Henderson is superintendent of the city water-works.

THE CAMP CLAYPIPE CONDUIT made by the H. B. Camp & Company, of Greentown, O., is a favorite with electrical companies, as shown by its frequent use. Last month we mentioned the employment of Camp conduit on the Niagara-Buffalo transmission. The Central Union Telephone Company have laid this conduit in Toledo and Columbus, O., this year, and will use about 50 miles at Indianapolis.

MINNEAPOLIS, MINN.—The St. Anthony Water Power Company have closed a contract for fourteen pairs of horizontal water wheels to be used in the power house at the new dam. The Stillwell-Bierce & Smith-Vaile Company, of Dayton, Ohio, was the successful bidder. These water wheels are to be 42 inches in diameter, with cylinder gates, and, in connection with the dynamos, will be expected to develop a minimum of 9,000 horse power.

THE AMERICAN ELECTRIC TELEPHONE COMPANY, Kokomo, Ind., reports satisfactory business, notwithstanding the lateness of the season. The following contracts have recently been filled: Crown Point, Ind., exchange outfit for 150 telephones; North Manchester, Ind., 100 telephones; Georgetown, Ky., 100 telephones; Montpelier, Ind., 100 phones, besides an order for a full telephone equipment for Fort Crook, Neb. This latter order comes from the War Department.

THE AMERICAN BLOWER COMPANY, Detroit, Mich., have just issued a very handsome quarto catalogue of 208 pages, beautifully illustrated and in two or three colors of ink, devoted to their apparatus for heating, ventilating and drying. Aside from its attractive appearance and arrangement, the book is of a high order of merit and its contents embody data that is of the utmost value to engineers, contractors and architects. The problems of ventilation are dealt wtih very thoroughly.

THE AMERICAN BATTERY CO., 40 West Quincy street, Chicago, recently closed a large order for storage batteries with the Pullman Palace Car Company. This order which will amount to several thousand dollars, goes to show that the future outlook for a speedy revival of trade is good. The American Battery Co., have also been the recipients of several other smaller orders, and report that they have as much as they will be able to attend to for more than a month to come.

THE ELWELL-PARKER ELECTRIC COMPANY, OF AMERICA, whose factory and headquarters are in Cleveland, with branch in the Havemeyer building, this city, W. A. Stadelman, manager, announce themselves as ready to build generators and motors from 1 horse-power up to 1,200 horse-power, as well as special power apparatus. They have already turned out some admirable electrical machinery, and their apparatus is destined to enjoy large and growing favor. The company invite inquiries and correspondence.

LUNDELL MOTORS WEST.—The Western Electric Company, of Chicago, has been given an agency for the complete line of Lundell power motors, which range in size from one-sixteenth of a horse power up to any size required. These motors are completely encased, and are generally regarded among the trade to be one of the best motors on the market. They can be readily connected to printing presses, ventilating fans, and are also used for blowing large organs, and wherever electric power is desired these motors are especially applicable. These motors will be kept in stock in Chicago subject to immediate delivery, and prices and full information will be given upon application.

THE STANDARD UNDERGROUND CABLE COMPANY, of Pittsburg, has opened a branch office in room 507 Security Building, St. Louis, with Mr. F. C. Cosby in charge. Mr. Cosby previously held the position of assistant to Mr. J. R. Wiley, manager of the Chicago office of the company, and is well suited for his new duties, in which he has the best wishes of his many friends. Mr. Wiley reports that the business of this enterprising concern is still very brisk, and that there are good prospects for a still further increase in the near future. Mr. Wiley has just returned from a trip to St. Louis, and he is keeping his weather eye open in expectation of making some good deals in the Mound City before very long.

THE CORRESPONDENCE SCHOOL OF TECHNOLOGY, Cleveland, O., reports still another addition to its force of instructors. Mr. I. H. Sherwood, a graduate of Case School of Applied Science has been employed by the firm of E. P. Roberts & Co., and will also assist as instructor in the Correspondence. Mr. Sherwood worked as a machinist before going to college, and as a machinist and engineer during the time he was at college, and is now a licensed stationary engineer. Mr. Sherwood's experience is such as makes him able to thoroughly appreciate not only the value of an education, but the difficulties and trials met by those who have to obtain same by their own efforts. Mr. Sherwood is also assistant instructor in electrical engineering in the Y. M. C. A. course in Cleveland.

ELECTRIC APPLIANCE COMPANY.—The degree of success attained with enclosed arc lamps is largely dependent on the carbon used and it has been a difficult matter to find a carbon exactly suited to that work. Manufacturers of enclosed arc lamps are, however, rapidly coming to the conclusion that the "Electra" high-grade "Nuernberg" carbon is the proper one to use and the majority of such manufacturers are recommending and urging the use of "Electra" carbons with their lamps. So great has been the demand for "Electra" carbons for enclosed arc lamps that it has been impossible during the past few months to import them fast enough. The Electric Appliance Company report a splendid business in these goods, and state that all of their customers are more than pleased with them.

THE MISSOURI TELEPHONE MANUFACTURING COMPANY, St. Louis, are still retaining their record of constantly keeping busy. They are at present building ten exchanges complete, to be installed in various parts of the United States. They are placing their own engine, and will generate their own power. They claim to be the only telephone manufacturers who make every part of their own instrument upon the premises, inclusive of their woodwork. This company have now in press their new catalogue, which will be one of the most complete on the market, and they will be pleased to send one upon application. They also have issued 10,000 copies of one of the handsomest calendars ever given away gratis. They solicit correspondence on anything pertaining to telephones, toll lines, or private lines, and manufacture the most complete line of telephones upon the market. They make 12 styles of microphones, 25 styles of instruments and 4 styles of switchboards.

MR. E. W. HAMMER, informs us that he has disposed of his controlling interest in the Cutler-Hammer Manufacturing Company, Chicago, and will sever his connection with that concern on January 1, 1897. Mr. Hammer states that it is his intention to take a long and much needed rest, and that he will afterwards re-embark in the same line of the electrical business that he is engaged in at present. Mr. Hammer states that he will always take a lively interest in the welfare of his old concern, with which he has been connected since its birth, and notwithstanding that since the starting of the business it had to contend against unusually bad times, its rapid growth to its present prosperous condition goes to show how much may be achieved by indomitable energy, and strict business integrity, and Messrs. Cutler and Hammer are to be congratulated on their success in the face of the severe obstacles with which they had to contend. When Mr. Hammer returns to the electrical business we trust he will have the same prosperity with which his former efforts were rewarded.

NEW ENGLAND NOTES.

HYDE PARK, MASS.—The Hyde Park Street Railway Company are erecting a new power station. The boiler room is 44 feet wide and 87 feet long, and the engine room is 56 feet wide and 115 feet long. The building is to have brick walls, and the roof is to be supported by steel trusses. The steel work has been designed and will be furnished and erected by the Berlin Iron Bridge Company, of East Berlin, Conn. gree of vacuum. The purified for boiler feed supply asrdji

THE POPE MANUFACTURING COMPANY, Hartsford, Conn., have brought out for 1897 the twelfth annual issue of their excellent Columbia desk calendar. It is far more than a daily reminder of the glories of the Columbia wheel. It is neat, useful, tasteful, with special little touches of convenience and handiness, suggestive, like all Columbia things, of the highest economy of time and space.

THE RHODE ISLAND TOOL COMPANY, of Providence, R. I., have placed the contract for their new galvanizing room with the Berlin Iron Bridge Company, of East Berlin, Conn. The building will be a fireproof structure throughout, no woodwork being used.

THE AMERICAN ELECTRIC HEATING CORPORATION say: "The small 4½ in. stove recently put on the market by the American Electric Heating Corporation, of Boston and Chicago, proves to be even more popular than was anticipated and not only is it being largely used in the household, but it fills one of those 'long felt wants' or 'aching voids.'"

THE MOSSBERG AND GRANVILLE MANUFACTURING COMPANY, 101 Sabin street, Providence, R. I., whose removal from Attleboro, Mass., has just been completed, occupy in their new quarters more than two acres of floor space, and are there operating a most complete modern shop. On the first floor are the stock room, heavy machinery, radial drills and large steam hammer. On the second floor are the lathes, milling machines and large grinding shop, tool rooms and test-rooms. On the third floor are the draughting room, pattern shop, photographic department and storerooms. A private elevator connects all floors. The offices, which occupy the entire front of this floor, are finished in sheet steel and oak, and are most complete in every detail. Among their specialties may be mentioned a press, which punches armature sheets complete at one operation.

THE WENSTROM ELECTRIC CO. stockholders held their annual meeting last week at Baltimore. The vote for directors to serve during the ensuing year resulted in the choice of Messrs. Gaun M. Hutton, F. C. Latrobe, Robert Rennert, H. Marcus Denison, Peter E. Tome, Seymour Mandelbaum and James A. Gary. Mr. Gary was chosen in place of Mr. J. M. Denison. Mr. Rennert entertained those present at luncheon at the Hotel Rennert.

Department News Items will be found in advertising pages.

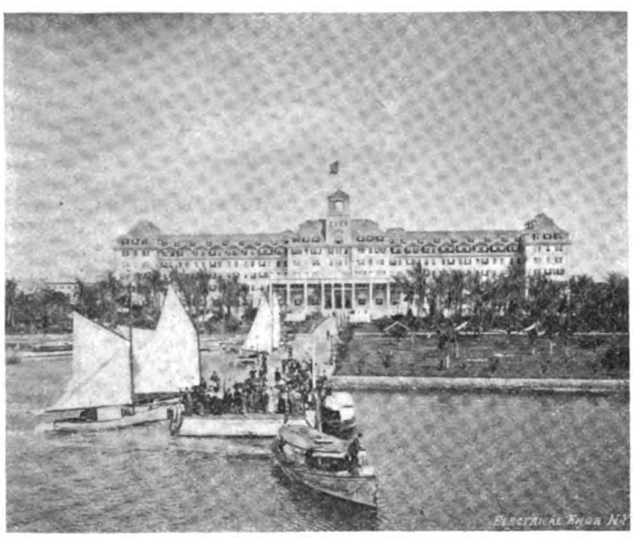
Electrical Engineer.

Vol. XXII. DECEMBER 30, 1896. No. 452.

ELECTRIC LIGHTING.

ELECTRIC LIGHTING OF THE ROYAL POINCIANA HOTEL AT PALM BEACH, FLORIDA.

THE rigor of our Northern climate annually compels many thousands to seek more agreeable climates, and year after year Florida has been gaining in popularity as a winter



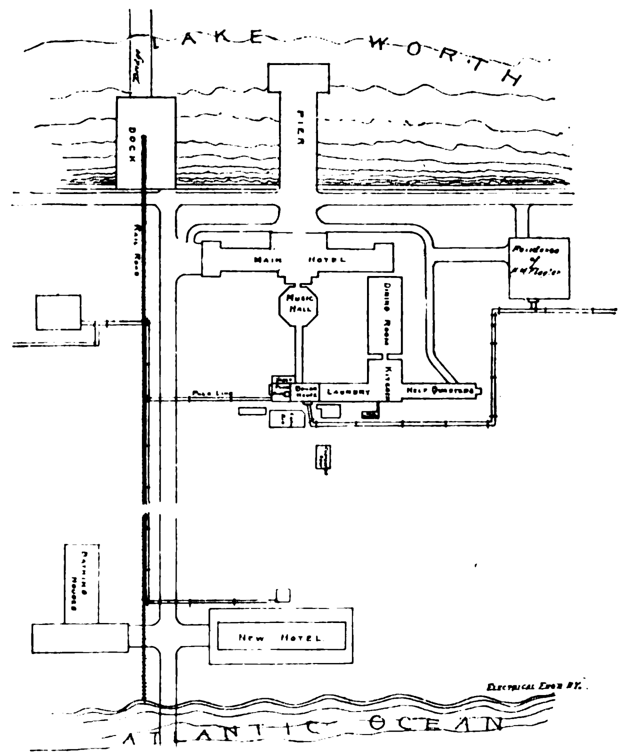
THE ROYAL POINCIANA HOTEL, PALM BEACH, FLORIDA.

resort. Mr. Henry M. Flagler, whose energy and enterprise has already created many beautiful resorts in that enchanting region, has recently added another, which has already secured

POWER HOUSE WITH CONVERTERS AT THE ROYAL POINCIANA.

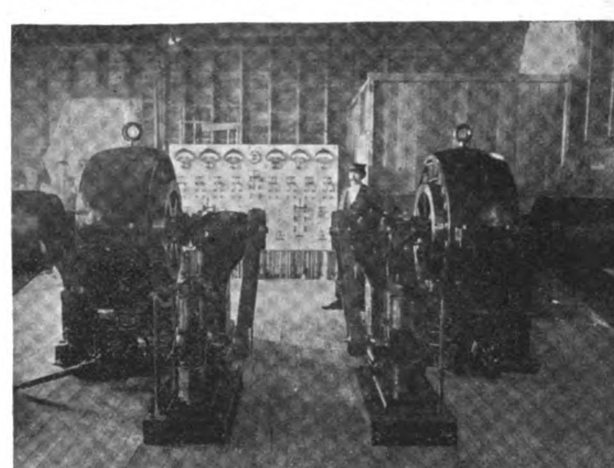
for itself an enviable reputation for the beauty of its surroundings and the elegance and completeness of its equipment.

This new resort, Palm Beach, with the Royal Poinciana, is situated on the east coast of Florida. The main hotel faces Lake Worth, as shown in the accompanying map. It is 600 feet long, with wings, running at right angles, whose capacity is double that of the main building. This lake is situated



PLAN OF HOTELS AND SURROUNDINGS, PALM BEACH, FLORIDA.

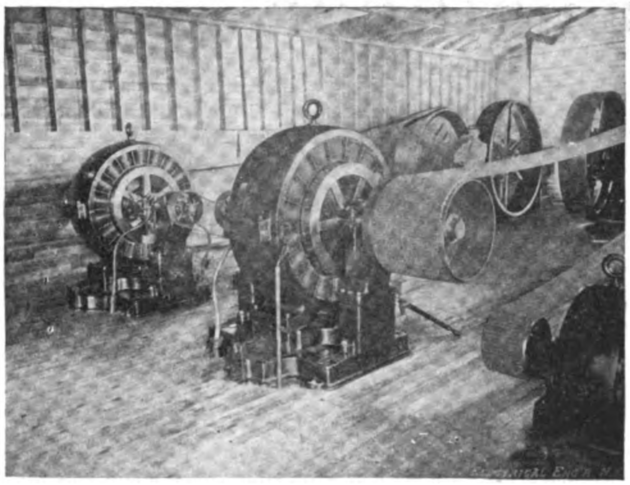
about 3,000 feet from the shores of the ocean, and is connected with the latter by a beautiful road shaded by palms on both sides. At the ocean terminus of this road another hotel, known as the Palm Beach Inn, has been erected, for those



VIEW IN DYNAMO ROOM, ROYAL POINCIANA.

who prefer direct ocean breezes and greater proximity to the sea.

Following Mr. Flagler's previous work in this direction no other illumination but that by electricity was at all considered. The electric lighting plant installed presents a number of novel features and was laid out so as to afford current for both hotels. For this purpose a power house was erected in the rear of the Royal Poinciana, with a capacity for 9,000 lights. The

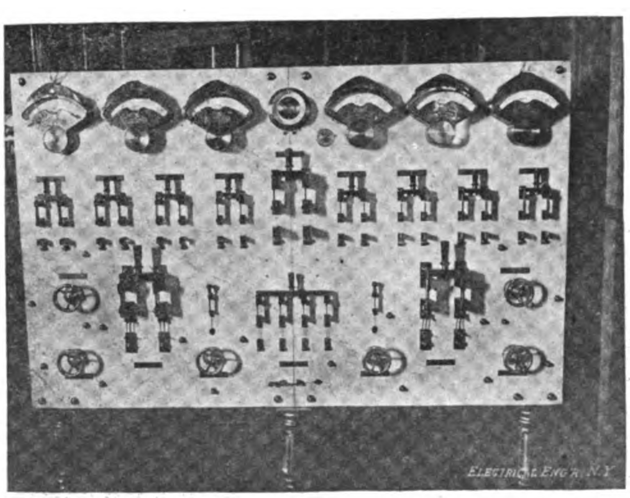


La Roche Alternators, The Royal Poinciana.

current is generated by three La Roche 150 kilowatt alternators and one 25 kilowatt alternator, two views of the dynamo room being shown in the accompanying illustrations. These dynamos are belted to three tandem compound non-condensing Ideal engines, built by the Harrisburg Foundry and Machine Co.

The alternators are wound for 300 volts and the circuits at this potential run directly into the hotel through underground ducts of the Interior Conduit and Insulation type, and up the elevator shafts at the same potential, 300 volts. On every floor close beside the elevator shafts there are placed panel closets, as shown in the accompanying engraving, each closet containing a distributing board in which is mounted a step-down transformer, which lowers the potential from 300 to 112 volts, which is the working voltage.

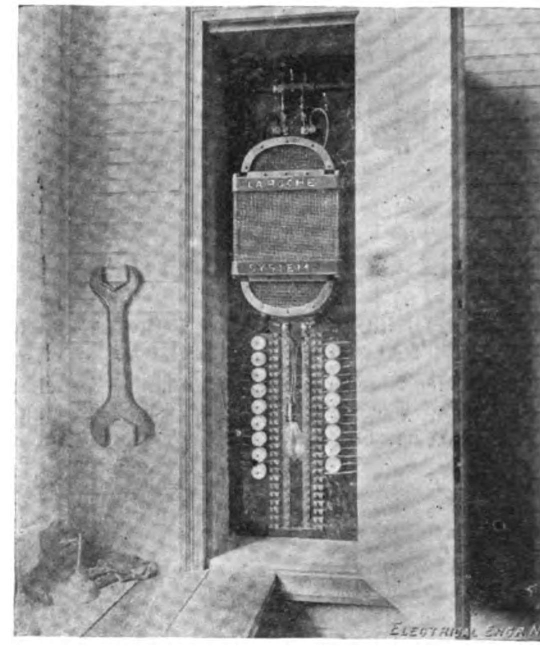
The switchboard employed at the power house is designed on an original plan, and is so arranged as to provide for the



Switchboard in Lighting Plant, Royal Poinciana.

varying amounts of lights used in the hotel at different times, so as to connect the machines in the most economical way, as the load changes. The switchboard contains two main switches and a relay switch. The latter connects the three bus-bars in multiple, which are then fed by a small engine and dynamo, which carries the day load of all circuits.

The alternating generators are operated in parallel, a method which has made very little, if any, progress in this country, although we are told that it is frequently done abroad. The manner in which the running in parallel is carried out is quite simple and is worthy of notice. The two engines carry the main night load. The governor is removed from one of these engines. In starting up, the governing engine is first given steam and brought up to full working speed, and its dynamo

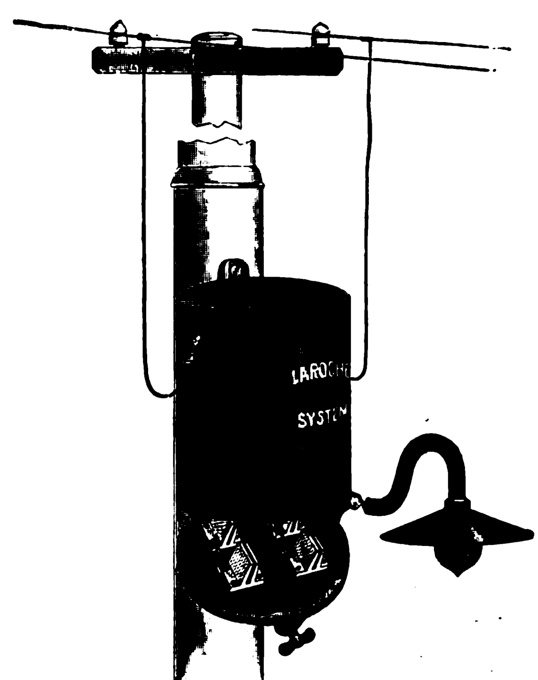


Floor Panel Closet in the Royal Poinciana.

switched into the circuit. The engine without a governor is then started and when up to speed the alternator immediately falls into step, and the governing of both engines is accomplished by the single governor, the second alternator governing its own engine and being kept in speed by its mate. No difficulty of any kind has been experienced with this method.

The three boilers are of 600 horse-power, total capacity, of the Gary water tube type.

For supplying current to the Palm Beach Inn about a mile



La Roche Converter for Pole Lights.

distant, the 300 volts primary current generated by the dynamos is led into four 30 kilowatt step-up transformers mounted on supports in front of the power house, as shown in the accompanying engraving. The transformers raise the potential to 1,000 volts, at which it is carried to the Palm Beach Inn.

There it enters the step-down transformers placed in a special transformer house erected for that purpose, and the current is reduced to 112 volts and fed directly to the lighting circuits through panel closets in the same manner as at the Poinciana.

The road leading to Palm Beach is illuminated at night by

PALM BEACH ROAD, PALM BEACH, FLORIDA.

one hundred 50 candle-power lamps placed under reflectors, after the manner shown in the accompanying engraving. These lamps are fed by the small converters shown, which are mounted on poles, the majority of them having arms extending out above the middle of the road. The converters, as will be seen, have the switch contacts mounted on a cover which opens downward. Thus by loosening a screw or a spring catch, and throwing the cover down, the circuit is completely broken and the converter can be handled and fuses renewed without danger to the attendant.

In addition to furnishing current for the Palm Beach Inn, the power house at the Poinciana has three additional large step-up transformers which raise the potential from 300 volts to 2,000 volts, at which it is carried to a point four miles off at South Palm Beach, and also to various private residences at North Beach, a few miles to the north.

The entire system of lighting above described was designed by Mr. F. A. La Roche, of the Ideal Electric Co., who also built the entire apparatus. The installation has been admirably carried out by Mr. A. V. Best, engineer and electrician. Mr. Best has charge of all of the electrical work of Mr. Henry

A. V. BEST.

M. Flagler, and it was he who remodeled the electrical work of the Hotel Ponce de Leon and Alcazar at St. Augustine.

BRAMBEL'S "ARCODESCENT SYSTEM."

Mr. Grant Brambel, of Sleepy Eye, Minn., is bringing out a new system, which seems a little behind the times: "This system of lighting consists of a dynamo, and commutator, from which may be drawn current for arc or incandescent light at pleasure of the consumer also a new pattern lamp for arc lighting and a new design of incandescent lamps. At present where consumers desire both arc and incandescent lights it is necessary to purchase two dynamos and wire for the two different currents, or to use what is called the series system, a very expensive and dangerous application of electricity. By using the Brambel System but one dynamo is used and one system of wiring. It is a very easily understood and very easily operated machine and the lamps used are much less expensive and easier to handle and care for than the arc light now commonly used. The Brambel System of electric lighting is certainly an economical system both to operate and to install."

ELECTRICITY IN CHRISTMAS STORE DECORATION.

IT is said by those who have made the round of the great retail stores this year that the resort to electricity for purposes of decoration, dazzlement and bewilderment has been on a larger scale than ever. Perhaps this is due in New York City to the entrance of the two new vigorous competitors into the lists for public favor; so that while the newer concerns

CHRISTMAS TREE AND OTHER LIGHTING EFFECTS, "BIG STORE," NEW YORK.

have tried to fill the public eye with visions of beauty in their stores, the old houses have resolved not to be outdone or cast into the shade. It seems positively unfair to pick out or point out any store, where all have done so much and employed the electric light so liberally; but it must be said that Siegel-Cooper's "Big Store," to which we have already drawn attention, was by far the largest user of electricity for Christmastide spectacle.

The main stairway was lavishly trimmed with verdant festoons and suspended above the balustrades were 60 Japanese lanterns, each containing one 16 candle-power Imperial lamp. On the second floor over the fountain and statue of The Republic (which was not in operation, owing to its basin being used for trade purposes), was a Christmas tree about 15 feet high, on which were strung 300 8 candle-power Imperial lamps (frosted and plain) in series of 3 and 8.

At the rear of the second floor was a cottage covered with snow in which sat a man dressed to represent Santa Claus. The interior was lighted electrically.

The window on 19th street and Sixth avenue contained toys of every description, shown on a moving platform operated by a chain and sprocket arrangement driven by a ½ horsepower Eddy motor, and lighted by 100 16 candle-power Imperial (frosted and plain) lamps. Next in order (on the Sixth avenue side) was a window containing a goodly display of grouped handkerchiefs. Every few moments the bottom gradually moved away disclosing a beautiful tinsel and color effect; then the pyramids of handkerchiefs one by one disappeared and their places were occupied by miniature fairies.

The next move carried the "back drop" skyward and revealed an elaborate floral scheme and finally the wings revolved transforming the whole arrangement into a fairy grove. In the "back drop" was a circular aperture 5 feet in diameter behind which, when the transformation was complete, was disclosed Santa Claus in a house, in the act of filling the stockings near the chimney. This effect was produced by having a piece of gauze covering the aperture, opaque when first seen, but becoming transparent when 12 32 candle-power Imperial lamps were turned on. These being frosted cast a glow over the whole. There were also in this window 75 16-candle-power Imperial frosted lamps concealed behind the "wings," among the "borders" and underneath the fairies.

In the window on the right side of the main entrance was a monster spider's web. In one side of the web was a spider whose eyes containing 4 candle-power Imperial lamps were blinked automatically by the aid of a commutator (built by the electrician of the house, Mr. G. K. Voight). The entangled fly also winked his eye. In this window 50 16 candle-power Imperial frosted lamps cast a mellow radiance on the goods.

Displayed in the window on Eighteenth street and Sixth avenue were the good things to be found on sale in the Book Department, six revolving pillars showing to advantage a choice line of "popular authors." These were driven by a belt and pulley system attached to a motor.

On Eighteenth street (next to the last entrance) was a clothing display. The window was trimmed in red fluted panels outlined in evergreen and tied in each corner by a white satin bow, seemingly held in place by a 16 candle-power Imperial lamp, frosted. There were 60 such lamps in this display.

The credit of the general "get-up" of the windows is due to Mr. Young, head trimmer, and of the electric effects to Mr. G. K. Voigt. It is to be borne in mind that all this lighting display was additional to the regular lighting of the store, with its thousands of incandescents, its hundreds of enclosed arcs, and its big search light. The place was as light as day all through the dark hours of the Christmas shopping season.

WAGONER, ARIZ.—Mr. Alex. O. Brodie writes us that the Walnut Grove Water Storage Company are engaged in preliminary work looking to the reconstruction of their dam, and a power transmission of considerable size. It will, however, be some time before anything is done in this direction.

THE ELECTRIC ARC FOR LANTERN PROJECTION.—III.

BY E. P. HOPKINS.

(Concluded.)

THE all important question is, how to maintain a steady, equal light.

First, at what angle should the carbons be in regard to the axis of the lenses? Should it be vertical or slanting? From experience I would say that an angle from 15 to 20 degs. is most suitable. This lamp, described in previous articles, is constructed at an angle of 16 degs. from the vertical. If the angle is too great flaming often occurs and usually at a most critical moment. I have come to the conclusion that the cause of flaming is almost entirely due to currents of air, except when a magnet is near, as in the case of an iron hood that nearly surrounds the carbons. It has been so marked with the alternating current that the flame was evidently magnetically blown back upon the center of the hood next to the body of the lamp which part became red hot, after about 20 minutes' burning without any change in the flame. I removed the hood, when there was no appearance of any flame. This principle has been used for searchlights when the horizontal carbons are used, and with very beneficial results. I have tried many experiments in this direction with a view to changing the position of the carbons, but have not come across anything that promised better work.

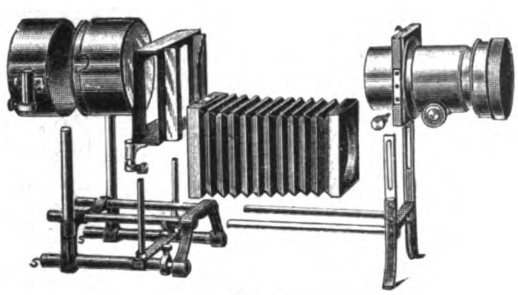


FIG. 9.

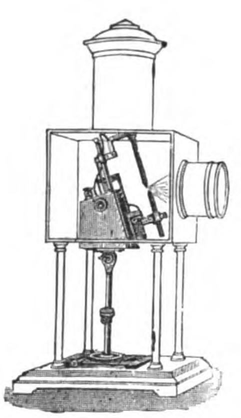

FIG. 10.

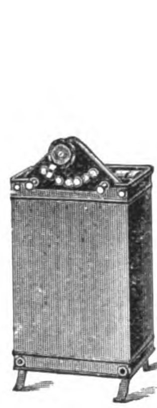

FIG. 11.

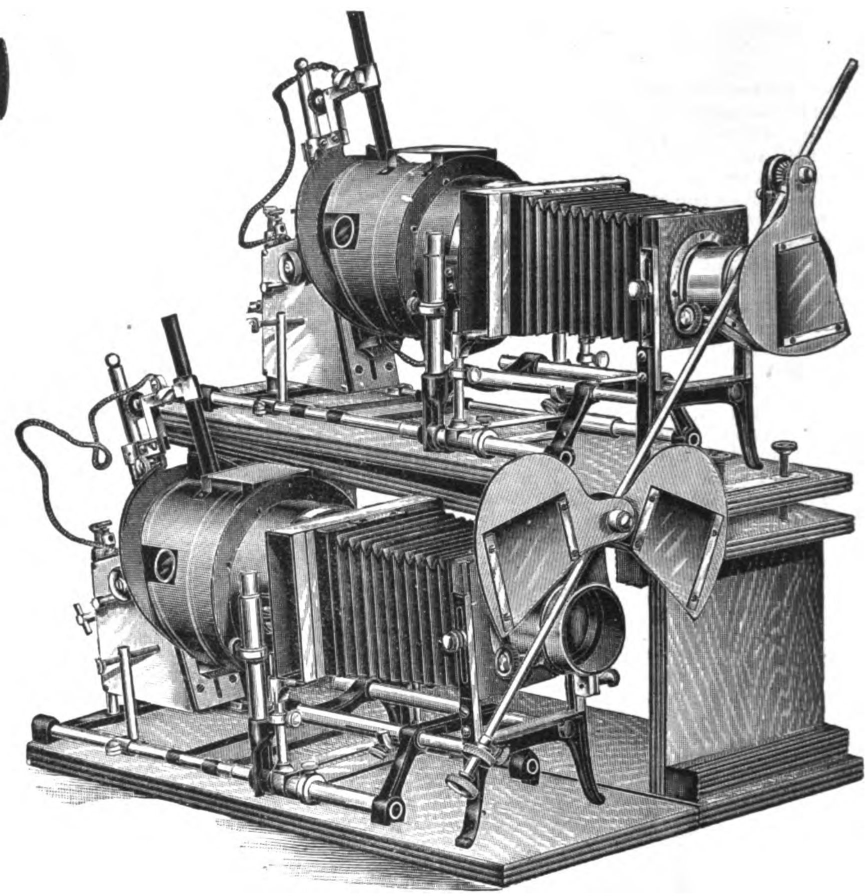

FIG. 12.—COLT DOUBLE ARC DISSOLVING LANTERN.

In order to avoid currents of air from affecting the arc and causing it to flame, an air and light shield is used, consisting of a small piece of sheet iron rivetted to the regular hood with a space cut out in front to allow the negative carbon to pass without touching. The arc is maintained ¾ inch above this shield so that currents of air cannot strike the arc directly. Flaming is sometimes caused by imperfections in the carbons, a piece chipping off and leaving a space for the arc to start up the side of the carbon. One peculiar phenomenon I have noticed and presume others have also, is that the resistance or counter e. m. f. of the arc is considerably reduced at the time of flaming, although the arc is increased in length from ¼ to ¾ or 1 inch and the current increases (naturally) if on a constant voltage circuit.

In starting a lamp with new carbons, it will be necessary, in

order to get a good equal light on the screen, to draw the upper carbon considerably behind the lower, or negative, so that the arc will be forced to the outer edge of the positive carbon and so burn that part away and form an arc in the right position. Then it will be necessary to push the carbon forward again to avoid flaming. When once the carbons have been properly formed or burnt into shape, it will not be necessary to readjust them. In Fig. 7, illustrated in a previous article, the carbons are in the best position for general work and will remain so. There are 7-16 inch Electra carbons, with soft cores, positive and negative. Solid carbons of less diameter may be used with good effect, and sometimes with better results than when both carbons are of the same diameter, but for general work I have been able to get equally good results with both arrangements, and as the former makes it much simpler for the novice, as he cannot make a mistake, the lamps are usually operated with the same sized carbons for both positive and negative. For lantern work Electra carbons are decidedly superior to any other, and I have tried all that I could get hold of. I wish some one would manufacture carbons in America that were good enough, as it is very inconvenient waiting for importation for the special size that one requires, as, of course, just the size needed is out of stock.

Fig. 9 illustrates the lantern part dissected, showing that each part can be easily removed or exchanged in case it becomes damaged. Notice should be taken of the condenser cell, which is close to and just outside its supporting collar, which is supported by side clamps on two upright posts so that the center of the lenses can be adjusted to suit the height of the illuminant. It will be noticed that the other parts, the slide box and the support of the objective lens, are adjustable in the same manner. The bellows between the two being fixed to them will, of course, move with them. For oxyhydrogen light this makes an extremely compact lantern, as the parts can be set as low as possible so that they will not take up much room, and when two or more lanterns are supported, one over the other, it makes a comparatively small piece of apparatus. The convenient detachment of the front support and lens enables what we term an optical bench to be attached in its place to the body of the lantern. On this optical bench can be placed or adjusted any system or set of lenses or apparatus that may be required for the whole field of projection work.

As many colleges and demonstrators have already on hand the rather elaborate Morton lantern, it has been found very necessary to adapt this electric lamp to that form. On account of its small size, the lamp lends itself very conveniently to its adaptation, as shown in Fig. 10. The supporting post has a sliding joint which is fixed firmly by a set screw and raised or lowered by a thumbscrew, which is threaded on the post itself. The side motion to the right or left is produced by a worm-wheel fixed to the base of the post and turned by a screw knob. The adjustment back and forth for the focus of the condensers is obtained by sliding the support of the post in a groove in the base.

Fig. 11 illustrates the compact adjustable rheostat. It consists of two iron frames, supported on feet about two inches from the ground. These frames are insulated with asbestos and stretched over them, up and down, are German silver coil springs. The case, which is Russia iron lined with asbestos, acts as a form of flue or chimney, thus causing a draught of air to pass through all the coils, so that with one frame we can dissipate with ease 1,000 watts. This frame is 8 inches wide by 12½ inches long. As this adjustable rheostat has two frames, one for adjustment and the other for the highest amount of current that the adjustment will allow, it will be 6 inches wide, but if the adjustment part is not required, only one frame is needed, in which case it will be only 3 inches wide. This clamping together of frames makes an extremely convenient form of rheostat, which can be adapted to any circuit, even that of 500 volts, which takes 7 frames. The wire of which these rheostats are made is German silver. If iron were used, and the same amount, it would become so heated that its resistance would vary greatly. I have tried the special high resistance wire of Krupp, but find that although it requires less wire, we cannot make it very much smaller on account of ventilation and the cost is very little reduced, and as German silver is a staple article on the market, and can always be obtained at a low price, it is more satisfactory.

Fig. 12 shows a pair of electric lanterns, so arranged that they can be operated at one side of the apparatus. The dissolving device is conveniently arranged by having two vanes which are supported above the lenses, which move in opposite directions by turning the bar which operates them by means of a bevel gear. These vanes are made of metal, with the center part cut away, which is covered by plates of mica which have been blackened towards the inner edge and shaded off to transparency at the outer edge. When the rod is moved, one pair of vanes is opened or separated, while with the second pair in this case, the lower lantern is brought together, and on account of the shaded mica the light is very gradually cut off from the lower lantern, and, at the same time, put on from the upper lantern, the two lanterns being registered so that they superpose their respective pictures on the same screen, as is always the case with dissolving lanterns. There was great difficulty experienced in obtaining dissolving effects with the electric light on account of not being able to adjust the brilliancy of the lamp when starting. In this case, both lamps remain burning and very effective results are produced by the dissolver in front of the lens, as above described.

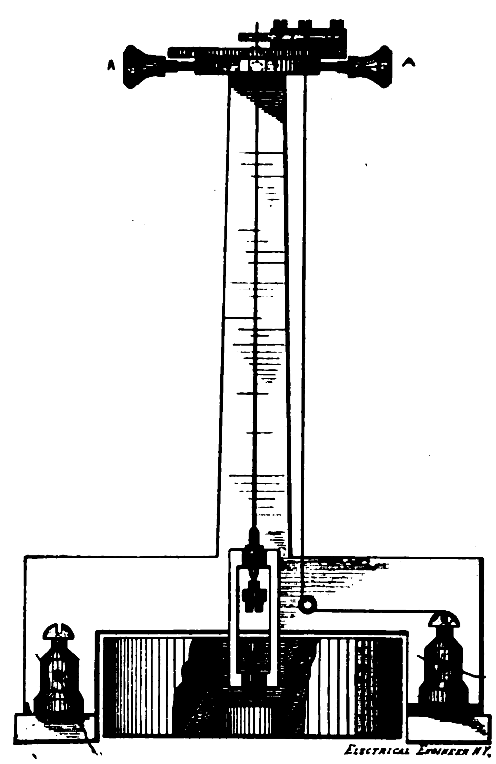
All the apparatus referred to in this article is manufactured by J. B. Colt & Co., of 117 Nassau street, New York.

MISCELLANEOUS.

THE ELECTRICAL SEISMOGRAPH AT THE WEATHER BUREAU, WASHINGTON.

BY NEVIL MONROE HOPKINS.

PERHAPS no other of the numerous pieces of apparatus at the National Weather Bureau, at Washington, has a more interesting and at the same time weird task to perform than the electrical seismograph, or recorder of the tremblings of the earth. While the instruments in use at the weather bu- of precision and measurement it would indeed be difficult to design and construct a piece of apparatus of more beauty and capable of finer adjustment. The majority of instruments in use to-day at the weather bureau are dependent on electrical circuits for their working, including the present seis-



SEISMOGRAPH IN U. S. WEATHER BUREAU, WASHINGTON, D. C.

mograph. The present instrument is shown in the illustration, being so simple in principle that a few words suffice for its description.

A heavy frame supports a cylindrical lead weight by means of a short steel stirrup having two hardened bearings allowing the weight ease of motion. A long slender pointer is rigidly connected with the upper end of the link, being tipped with platinum where it passes through a minute hole in a platinum plate. The screws A A serve to adjust the plate and are four in number. The little instrument which measures about 12 inches in height is kept under a glass shade in a stone chamber by itself in the sub-cellars of the instrument building.

The recording instrument consists of a chronograph which is situated in the second story of another building near by. Periodically an electrical circuit is closed through the system

by clock work, making a dash or offset on the paper carried by the chronograph cylinder to show that the instruments are in working order. Should seismic disturbances take place a series of dashes or offsets would be recorded showing the hour and minute of the beginning and cessation of the earth's oscillations or quakings. It is claimed that feeble tremblings of the earth, that would be of much scientific interest, would take place unobserved but for delicate means to record them, and properly designed and constructed apparatus, and last, but not least, properly installed apparatus, are sure to lead to interesting data.

The present piece of apparatus is mounted on an iron standard about three feet high which is firmly bolted to a stone slab which rests on heavy cement foundations entirely independent of those of the building. Various devices have been thought of to record disturbances of the crust of the earth, among them being a vessel of mercury imbedded in the earth serving to reflect a beam of light against a strip of sensitized paper moved by clock work. It may be interesting to note that Charleston, S. C., has made application for a seismograph, with its several attachments. The instrument just described was designed by Prof. C. F. Marvin, Professor of Meteorology, United States Weather Bureau.

ELECTRICITY IN NAVAL LIFE.—XII.

BY LIEUT. B. A. FISKE, U. S. N.

DEPRESSION POSITION FINDER.

When the ground in the vicinity of the water is high, the distance of a vessel on the water can be found simply by mounting a telescope on an eminence, pointing it at the vessel's water line, and noting the angle of depression of the telescope below the horizontal. The height being known, the distance is inversely proportional to the sine of this angle, so that the instrument may be graduated at once in yards. The direction is obtained with equal simplicity, by noting the azimuth of the telescope, as shown on a horizontal circle. To make these measurements and send them to the guns automatically is the office of the instrument hereinafter described. Corrections are, of course, needed for the rise and fall of the tide and for changes in refraction. The special limitation of this class of apparatus is the fact that the smoke of guns frequently hides a vessel's water line altogether, as was conspicuously shown at the battle of the Yalu.

The apparatus consists in two principal parts, namely, a device for determining the distance and a device for determining the direction or bearing of the object. The said two parts are used conjointly, and thereby the location of the object may be recognized upon a chart representing the area of the harbor, for example, drawn on a reduced scale.

In the accompanying drawings, Fig. 38 is a diagram illustrating the operation of the distance or range finder. Fig. 37 is a diagram illustrating the operation both of the range finder and of that part of the apparatus which shows the bearings of the distant object. Fig. 37 is a diagram illustrating the operation both of the range finder and of that part of the apparatus which shows the bearing of the distant object. Fig. 39 is a side elevation of the observer's instrument and shows the mechanism thereof on a larger scale and in detail.

Similar letters of reference indicate like parts.

Referring first to Fig. 38, A is a telescope, sight bar,, or other like means of directing the line of sight, indicated by the dotted line upon the object B. This telescope is to be located upon an elevation adjacent to the waterway to be protected. The telescope is pivoted at its outer end, so that it can be depressed through any desired angle in order to bring it to bear upon the object. The telescope is provided near its sight end with a contact piece or wiper which always bears upon a body of conducting material, represented symbolically at C. Connected with the ends of the body C is a voltaic battery, D, and connected in circuit with one end, E, of the body, C, and with the movable wiper or contact piece carried by the telescope A is a galvanometer, F. It will be apparent that as the telescope A is moved on its pivot its contact piece or wiper will be carried along the body C, and, as a consequence, a greater or less amount of the body C will be brought into the circuit which includes the galvanometer F. Inasmuch as the body C is to be constructed of, for example, a wire of uniform resistance per unit of length, it is obvious that as the telescope A is moved and a greater or less length of said wire is brought into the galvanometer circuit, the resistance thus interposed in said circuit will be increased or diminished; and as this length, and hence this resistance depends upon the angle of depression of the telescope, it becomes a function of the angle of depression; and, equally, the deflection of the galvanometer F, due to this change, is also a function of the angle of depression. Therefore, knowing the height of the telescope above the level of the object, the galvanometer deflection will indi-

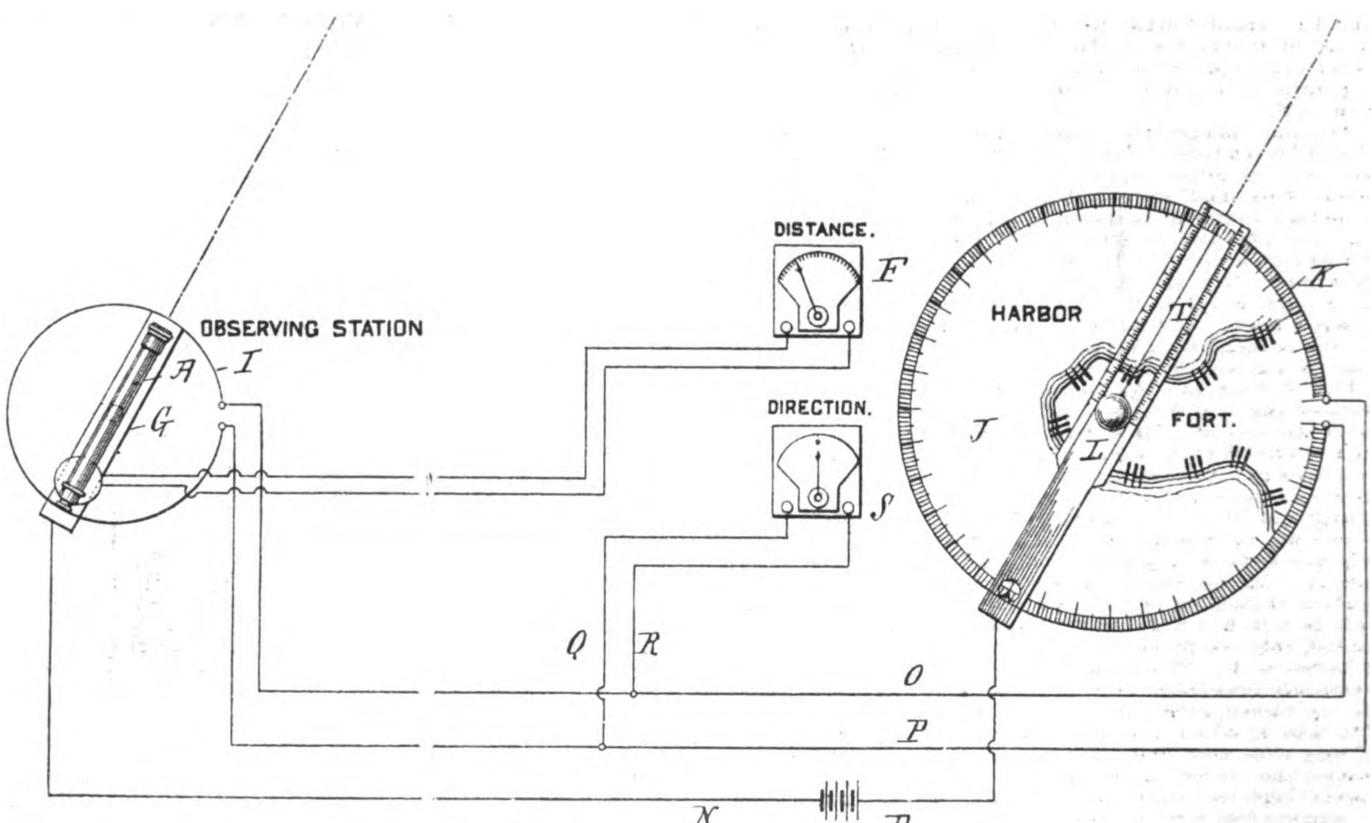


Fig. 37.—Position Finder.

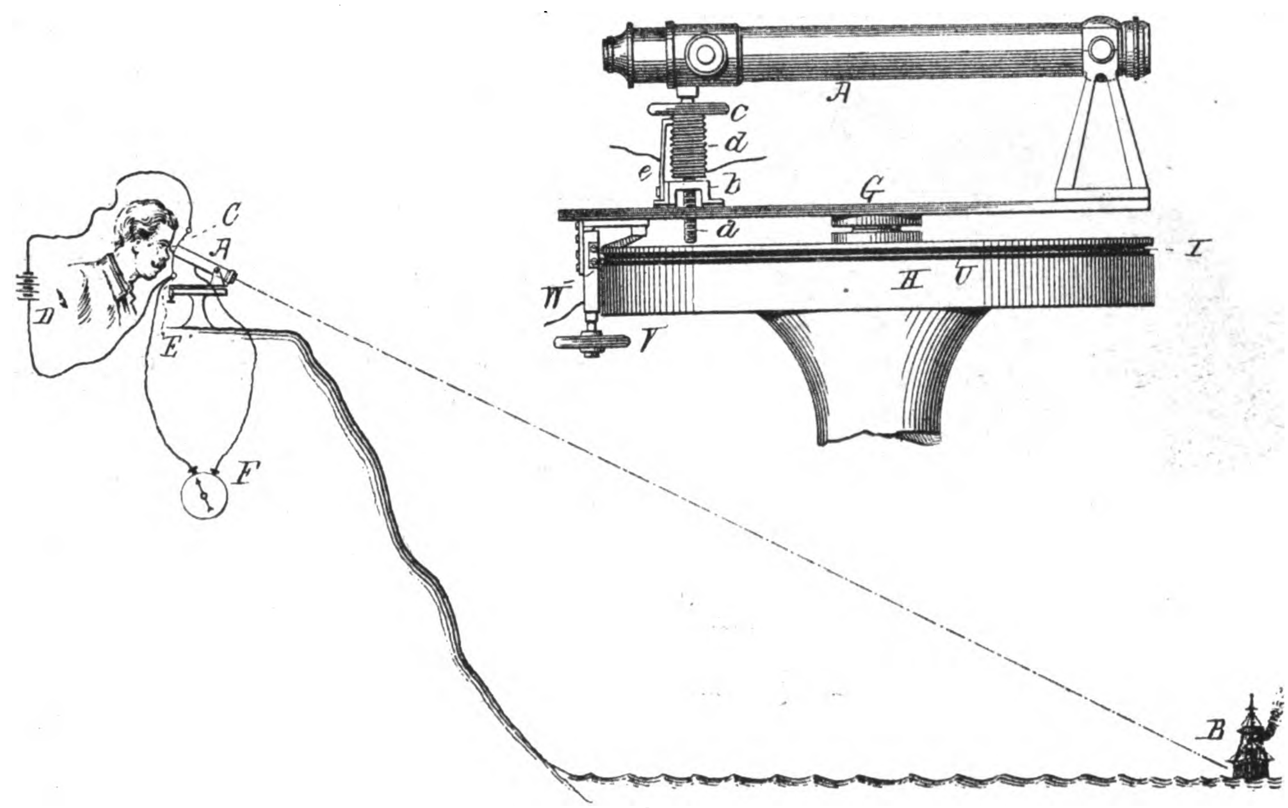
cate the distance of the object from the telescope, for which purpose the galvanometer may be once for all graduated in any suitable unit, such as meters or yards. Hence, if the galvanometer be located at a station distant from that telescope, an observer at that distant station, by reading the galvanometer, can recognize at once the distance of the object, while the person stationed at the telescope has nothing to do but to keep it properly directed upon the object.

The telescope pivot is carried upon a bar G, Fig. 39, which is pivoted upon a circular table, H. Placed in a groove around the periphery of this table is a wire I, Fig. 37, of conducting material, having a uniform resistance per unit of length. Upon the bar G is supported a contact piece or wiper, as will be more particularly explained hereinafter with reference to Fig. 39, which contact piece or wiper always bears upon the wire I. At the distant station, Fig. 37, there may be arranged a circular table, J, having around its periphery a wire, K, similar in all respects to the wire I. Upon the table J is pivoted a bar, L, which bar L carries a wiper or contact point which constantly presses upon the wire K. The contact point on the bar G and the contact point on the bar L are connected by a wire, N, which also includes the battery D. The ends of the wires K and I are connected by wires O and P, and said wires O and P are respectively connected to wires Q and R, which lead to the terminals of a galvanometer, S. It will be obvious, by a simple inspection of the drawing, Fig. 37, that the wires I and K at the separated stations and the pivoted bars G and L, together with the battery and the galvanometer S, are connected in Wheatstone bridge circuit, and that a movement of either the bar L or the bar G, displacing the contact pieces over the wires K or I, will vary the resistance of the bridge arms so that the bridge may be brought into or out of equilibrium by the movement of these bars upon their pivots; and further, it will be obvious that the fact when equilibrium is produced in the bridge will be made manifest by the movement of the pointer of the galvanometer S. The construction is to be such, therefore, and the instruments at the separated stations are to be placed with reference to one another, so that when the bar L makes the same azimuth angle with reference to one end of its wire K as does the bar G, then the bridge will balance and the galvanometer S will show zero; so that if the telescope A, and consequently the bar G, parallel thereto, be directed upon the object, the galvanometer S will indicate zero when the bar L is placed similarly to the bar G. If, then, on the table J there be disposed a chart of the area to be protected on a reduced scale, such, for example, as is shown in Fig. 37, the direction of the object from the point of observation will be indicated by the position of the bar L. For convenience in this respect the bar L is made with an opening containing a longitudinal wire, T; the position of the object on the chart being of course along this wire; also on the sides of the opening in the bar L may be marked a scale of distances, in yards or meters.

The operation of the whole apparatus is therefore as follows: The telescope A is depressed, and also moved in azimuth, until aligned with the object. Inasmuch as the distance of the object depends, as has already been explained, upon the angle of depression, and as this angle is measured by the galvanometer F in terms of distance, it is plain that if the galvanometer F be located at the station distant from the observer, then from that instrument the distance of the object can at once be read off. Simultaneously the movement of the telescope A in azimuth disturbs the balance of the bridge which includes the galvanometer S. The observer at the distant station then moves the bar L until the galvanometer S, placed near to him, shows zero. When this is done, the position of the object will be somewhere along the line of the wire T; and its exact point along that wire T is immediately found by noting on the scale on the bar L the distance corresponding to that shown by the galvanometer F. The bearing and distance of the object thus being ascertained, it remains simply to communicate this information, by any suitable means, to the guns or battery.



FIGS 38 AND 39.

It will be apparent that one of the advantages of this instrument is that it is directed by a single observer, and that the simple operation of aligning it with the target instantly causes, at the distant station (the bar L being suitably manipulated) indications from which the bearing and distance of the object may at once be recognized.

Referring now to Fig. 39, there is here illustrated, in detail, the mechanical construction of the telescope A and its supports. The table H may be of any suitable material, and should have embedded in it a ring U of hard rubber or other insulating material, in which ring is the groove in which is placed the wire I. The bar G is conveniently rotated on its pivot by means of the hand wheel V, the support for which wheel carries the contact point or wiper W. The inner end of the telescope A is supported on the vertical screw a, which passes through the fixed nut b which is carried on, but insulated from, the bar G, the insulation being placed below the nut. The screw a is rotated to depress and lower the telescope by means of the hand wheel c. Secured upon the screw is a cylinder, d, of ebonite, having upon its surface a spiral groove in which is laid the german silver wire corresponding to the body C, Fig. 38. e is a contact spring which always bears upon the wire C, and this spring is supported upon, but in-

sulated from, the nut b. In this device, instead of causing the telescope A to carry the contact and move it over a fixed body, C, as in Fig. 38, the body C, by the rotation of the screw a, is made to move under the fixed contact piece e; the relation of the parts being thus merely reversed. The circuit connections are the same as is indicated in Fig. 38, that is to say, the battery terminals lead to both ends of the wire C wrapped upon the cylinder d, and the terminals of galvanometer F connect respectively with the contact wiper e and one end of the wire C. The movement of the telescope A in azimuth is three hundred and fifty degrees.

Power Transmission.

ELECTRIC HOISTS AT THE HANOVER, PENN., MINES OF THE D., L. & W. R. R.

ONE of the most interesting mine hoist installations in the country is that at the mines of the Delaware, Lackawanna and Western Railroad, at Hanover, Pa., which is hand-

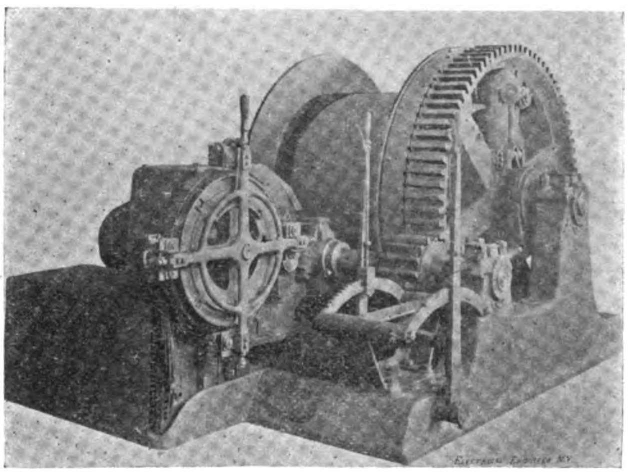


Fig. 1.—Mine Hoist Driven by Westinghouse Motor.

ling coal at a depth of 2,800 feet. There are two electrical hoists similar to that shown in Fig. 1, each capable of hand-

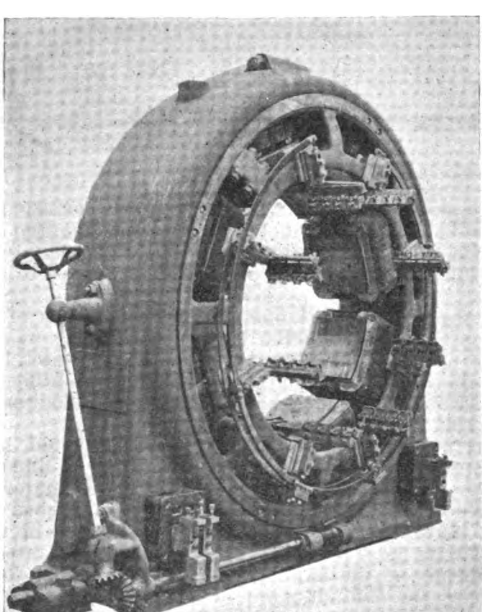

Fig. 2.—Field of Westinghouse Generator in Mine Hoisting Plant.

ling 2,800 feet of rope and hauling 10,000 pounds at a speed of 500 feet per minute up a 31 per cent. grade. These hoists, which were made by Webster, Camp & Lane, are driven by a 100-horse power Westinghouse steel motor (railway type), and the controller is of the Westinghouse commutator type. This plant, as will be seen, is very compact, the motor, the hoist and the controller being mounted on the same bed plate.

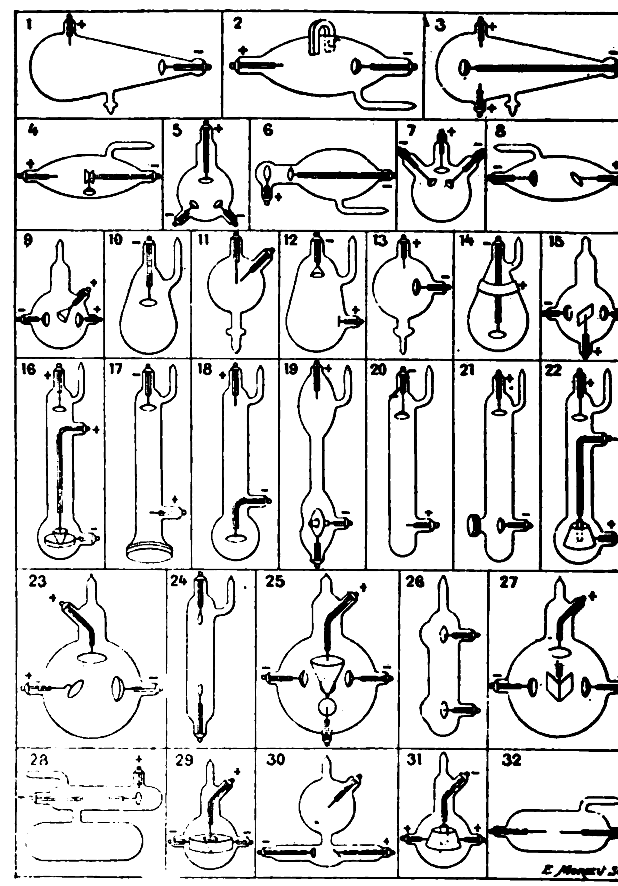
The power plant consists of a 150 k. w., 550-volt, 180 r. p. m. engine type Westinghouse generator, shown in Fig. 2, with the armature removed. This generator is driven direct by an Ames engine. There is a marble switchboard connected with the plant containing the instruments for regulating the operation of this machine. The plant has been in operation for some time, and the railroad company has expressed its great satisfaction with it.

Roentgen Rays.

VARIOUS TYPES OF X-RAY TUBES.

A LARGE number of tubes have already been employed in different experiments with, and applications of, the X-rays for photography, and in connection with the fluoroscope. Mr. G. Seguy has constructed and experimented upon several types and he has gathered a collection which is illustrated in our contemporary, "La Nature."

There exist at the present time three methods of obtaining the X-rays. That employed in the very beginning is based on the direct action of the ray. The second permits of obtaining instantaneity in the radiograph, and is based on a reflection action. The third is a result of a combination of the first two



Various Types of X-Ray Tubes.

methods. In the accompanying engravings, Nos. 1, 2, 3, 4, 6, 7, 10, 11, 12, 13, 14, 17, 18, 20, 21, 24, 26, 28 and 32 are constructed according to the principles of the first methods. Nos. 5, 8, 9, 15, 16, 23, 25, 27, 29 and 30 employ the second method; that is, the theory of the reflection of the cathode rays and of the phenomenon of internal electrolysis of the volatilized molecules. The tubes Nos. 19, 22 and 31 produce X-rays according to the two combined theories.

The numbers accompanying each tube designate the design of the various experimenters, as follows: 1 and 2, Crookes; 3, Séguy; 4, Wood; 5, Séguy; 6, Chabaud-Hurmuzescu; 7, Séguy; 8, Thomson; 9, Séguy; 10, d'Arsonval; 11, Séguy; 12, Puluj; 13, Séguy; 14, d'Arsonval; 15, Le Roux; 16, 17 and 18, Séguy; 19, de Rufz; 20, Crookes; 21, 22, 23, Séguy; 24, Röntgen; 25, Brunet-Séguy; 26, 27, Le Roux; 28, Colardeau; 29, Séguy; 30, Colardeau; 31, Séguy; 32, Röntgen.

Letters to the Editor.

THE DEFINITION OF "THERMO-ELECTRIC."

On page 651 of your last issue, Mr. Reed replies to my letter inquiring in what sense the term "thermo-electric" was used, in his former communication upon the Jacques cell. If I now understand him, he states that the thermo-electric action is not thermo-electric. I do not know of any authority for the use of the term except for electric energy produced by direct transformation of heat energy, and as Mr. Reed now states that there is no such transformation in the Jacques cell, that is equivalent to saying the action is not thermo-electric.

I cannot see that the action of the Jacques cell is any different from the action of any other electrolytic cell, as, for example, zinc-platinum in dilute acid. The fact that the Jacques cell must be raised to a certain temperature before any e. m. f. is exhibited makes no difference in the theory of its action; it simply means that at ordinary temperatures there is no oxidation of the carbon. When the proper temperature is reached an incipient oxidation takes place which causes the difference of potential between the two plates, and this difference of potential opposes further action. Now close the circuit; the accumulated charge is removed; the oxidation then goes on maintaining the current.

This is precisely what takes place in the zinc-platinum cell at ordinary temperatures. Very possibly, I may say very likely, at a sufficiently low temperature zinc would not oxidize. If so, at that temperature there would be no potential difference between the zinc and platinum of a zinc-platinum cell, and no current on closing the circuit. Then on raising the temperature to the point where zinc could be attacked, current would be generated. Assuming all this to be true, would anyone think of calling the action of such a cell thermo-electric?

New York, Dec. 24, 1896. W. A. ANTHONY.

THE EFFECT OF HARDENING PLASTIC RAIL BONDS.

I have heard it recently stated as an objection to the Edison plastic rail bond that the amalgam would sometimes harden. As I had a very long experience with the earlier forms of this alloy designed by Mr. Edison, I wish to say that on a road in Orange the bonds were mixed so as to harden and had four or five years successful use.

If a connection jarred loose from any cause the heat produced by increased resistance quickly softened the amalgam and re-established the contact. In designing the more modern form of this bond, it was decided to put in a slight excess of mercury and to allow sufficient room in the receptacle holding the alloy, to prevent its being put under pressure. This alloy when properly used, will remain plastic for years, as I can testify from long experience. If this alloy is put under pressure the excess of mercury is forced out, leaving a brilliant white metal of great density and of better conductivity than the plastic form. It readily softens under heat and will not be blackened by an arc. Roads whose joints are well maintained need not worry about contact if their plastic alloy is found hardened.

LAKE ONTARIO & RIVERSIDE RAILWAY CO.,
F. H. TIDMAN, Receiver.

Dec. 22, 1896.

CHICAGO SCHOOL OF ELECTRICITY.

My attention has been called to the fact that the Chicago School of Electricity is making use of my name in their advertisements. Such a use is altogether unauthorized. The work I did for the National School of Electricity on their "Lesson Leaves" was supposed to be for their classes entirely and was of the nature of a review of some of Prof. Jackson's writings. I have no connection with the Chicago School of Electricity and consider that their use of my name is of the nature of a breach of faith on the part of the managers of the National School of Electricity.

FREDERIC A. C. PERRINE.
Leland Stanford Junior University, Palo Alto, Cal.

RICHFORD, VT.—Mr. W. S. Foster, superintendent of the Richford Foundry Company, is lighting a town five miles away, from one of his power houses a short distance from Richford, in Canada; and he is also preparing to light another in the spring six miles from the power house. He is wishful of receiving circulars, catalogues, etc., and we shall be obliged if our friends will accommodate him.

News and Notes.

APPRENTICESHIP IN MACHINE CONSTRUCTION.

The "American Machinist," of New York, has been making an investigation of the apprenticeship question so far as it relates to those trades concerned in the production of machinery. The results are given, tabulated and in the form of letters from nearly all of the more prominent machinery building establishments and railway systems of the country, and show that, in those trades at least, apprenticeship is by no means a thing of the past, as many suppose it is, but that it is still generally practiced and believed in.

Of the 116 engine builders, machine-tool builders, railroad and locomotive shops and builders of miscellaneous machinery, replying to inquiries, nearly three-fourths take apprentices, and more than nine-tenths of these express themselves as satisfied with the workings of the system. Many of them express their approval of it in emphatic terms, and declare that apprenticeship is necessary, and that it is the duty and can be made to the advantage of every machine builder to take apprentices.

TELEPHONES AS ALARM CLOCKS.

The Johnstown, Pa., Telephone Company has all-night service at its central office, and has established in connection therewith a unique method of helping out those of its subscribers who do not care to trust themselves to get up at a certain desired hour without some outside assistance. It is a call system, something on the style of that in vogue at the hotels. The subscriber who wishes to wake at a certain hour calls up central and tells the operator, who "makes a note on 't." When the set hour arrives the operator rings up the subscriber who made the request. If he turns over and fondly imagines it's only an alarm clock he's fondly fooled, as the telephone bell will keep jingling until an answer is turned in to central, giving assurance that the sleeper is awake.

In the same manner if a physician is called for and cannot be reached, if requested he will be notified of the call as soon as he can be reached and told whence it came.

ARC LIGHT PRICES IN CANADA.

A report has been prepared as to the cost of electric lighting in various places throughout Ontario: Chatham, sixty-five lamps, all night, 23½ cents each per night; Brantford, fifty-five lights, all night, 23 cents; Cobourg, twenty-three lights, till midnight, 21 cents; Port Hope, thirty-three lamps, till midnight, 15 cents; Peterboro, all night, 25 cents; Kingston, one hundred and five lights, all night, 24¼ cents; Ingersoll, thirty-six lights, till midnight, 20 cents; Woodstock, seventy lights, till midnight, 19 cents; Belleville, sixty-one lights, all night, 24 cents; Galt, fifty lamps, till midnight, 23 cents; Hamilton, three hundred and sixty-nine lights, all night, 25 cents; Guelph, ninety lights, all night, 24½ cents; Owen Sound, thirty lamps, all night, 30 cents; London, three hundred lamps, all night, 30 cents.

A FEW TELEPHONE FIGURES.

It is estimated that to build the telephone line from Eastern Washington to Puget Sound points it will take 16,000 poles, 1,884 miles of No. 10 hard-drawn copper wire, 15,000 cross-arms and braces and 32,000 pins and insulators. The estimated cost of material and labor is $72,000.

THE ORTHOPÆDIC HOSPITAL in New York City has been equipped with a Röntgen ray apparatus.

CHICAGO DRAINAGE CANAL.—Some of the people interested in Niagara power enterprises are said to have formed the Chicago Electric Development Co. to utilize electrically the power obtainable from the water in the drainage canal. The nominal capital is $1,000,000.

NEW HAVEN, CONN.—The report of Lamp Inspector Hopkins states that the city uses on the streets 719 gas lamps, 504 naphtha lamps and 412 electric lights. The arcs on poles in the center of the city are to be placed on arms, they being now on poles. The Welsbach lights, of which there were 24 in use, are not to be adopted by the city.

ELECTRICAL WORKERS.—It is proposed by Electrical Workers' Union, No. 35, Boston, to agitate for the regulation of employment of wiremen by statutory law, on the ground of public safety.

VOL. XXII. NEW YORK, DECEMBER 30, 1896. No. 452.

CONTENTS.

EFFICIENCY OF CONDUIT ELECTRIC RAILWAYS.

AFTER another session of two days the directors of the Metropolitan Traction Company last week confirmed their previous decision to equip all the remaining horse car lines under their control in New York with electricity. It seems hardly likely that the trolley will be permitted, and hence a conduit or subsurface conducting system of some kind will in all likelihood be employed. Just what system will finally triumph is a matter of speculation, but there is an embarras de richesse rather than a dearth of such from which to choose, each making claims to special advantages. There seems to be an impression lurking in the minds of many that a conduit road must of necessity prove less efficient as a whole than a trolley road. Those imbued with this idea will therefore be particularly interested in the test of a conduit road at Washington, D. C., undertaken during the latter part of 1895 by Messrs. H. G. Ogden, Jr., and F. W. Heitkamp, for the subject of their Cornell graduating thesis, an abstract of which we find in the "Sibley Journal of Mechanical Engineering." The system tested was that designed by Mr. A. N. Connett, engineer of the Metropolitan road in Washington, in which the working conductor, a steel rail, is supported on porcelain insulators, the whole being protected from water and drippings by the overhanging slot rail.

The tests included the entire equipment and showed first that at the power house an electrical horse-power is generated for 2.57 pounds of coal, a very creditable figure for the size of station here in question. The car tests showed that the average efficiency of motors, including all stops, starts and curves, was about 60 per cent., while the average efficiency when the car was running at normal speed was 76.4 per cent. These figures are as good as are obtained on most existing trolley roads, and perhaps better than are attained on a good many such roads. If the traction co-efficient of 20 pounds per ton assumed represents the true condition of the track, and other running conditions, it would appear that some improvement in railway motor design would still be desirable. It goes without saying that a motor intended to afford a wide range of speeds cannot be designed to give as high efficiency as one built for a single speed, but the results cited above would seem to show that there is still something to work for, and well worth the doing. The line tests showed drops ranging from 8 to 10.5 per cent., dependence being had solely on the working conductors without feeders. This showing, however, can hardly be taken as a criterion, for the road tested has a length of four miles, is double track, and operates only twenty-six cars, that is, on a headway of about 3 to the mile. Where the traffic is heavier, as it would be unquestionably in New York, feeders would have to be employed to prevent excessive line drop. But it is interesting to know, nevertheless, that the rail-conductor by itself, entailed a loss of less than 2½ per cent.

Naturally most inquirers will turn to the figures of leakage. On this point the investigators were required to fall back on the records of the road itself, since, as they state correctly, a record taken during one day would constitute no adequate basis for judgment. The road's records show that during the three months extending from January to April the insulation resistance of the different circuits varied according to the weather, at times being fairly low; at others very high. The average total leakage was not above 4 or 5 amperes even in stormy weather with the track covered with slush. This is a remarkably good showing considering the length of the road, and comparing very favorably with overhead work. Mention must also be made of the fact observed, namely, that the insulation resistance of the negative conductor rail was always considerably less than that of the positive rail. This behavior is probably due to some electrolytic action which may have the effect of depositing salts on the insulator, and recalls the action noted in cable testing with positive and negative battery terminal to ground.

Taken as a whole, the tests demonstrate the road to be very efficient and well able to hold its own, in this respect, with the best trolley roads of similar length and working conditions.

As we go to press we learn that the Metropolitan conduit roads will represent an expenditure mounting towards $8,000,000. The General Electric Co. has the contract for seven 800 kilowatt generators and 600 railway motors. Two stations will supply current. The engines are to be those of the Pennsylvania Iron Works; the boilers, Babcock & Wilcox; the rails, Cambria Iron Works and Pennsylvania Steel Co. The contracts for car bodies and trucks are not yet let.

THE RECENT CHICAGO BANK FAILURE.

NO small amount of excitement has been created in financial circles throughout the country by the failure of one of the large banks in Chicago, and the sympathetic collapse of a few other banks and concerns in the West. The institution enjoyed a good reputation, but appears to have violated the banking laws—to say nothing of the laws of prudence—in placing an unduly and improperly large amount of its capital in the Calumet Electric Railway, of Chicago. The great Western city had weathered all the four serious financial storms of the past three panic-stricken years in good shape, but there had long been surprise and anxiety, for Chicago has always been a city where the enterprise and courage of its people has led to an unsafe expansion of credit, so that even in normal times, the margin is not a wide one. This year the Diamond match collapse and the closing of the Stock Exchange were signs of overburden, but the city came out of that ordeal bravely, and to-day, after all is said and done, its banks are in a splendidly solid and strong condition.

It is not for us at this distance to determine the full blame attributable to the officers of the National Bank of Illinois, but it seems to us that an unfair slur has been cast by the failure on electric railway enterprise. Persistent efforts have been made to discover on what basis the Clearing House Committee fixed the appraisement at $1,500,000. On this appraisement the net loss to the bank, which had advanced nearly $2,500,000 on the Calumet securities, was practically $1,000,000, or equal to the entire capital. It is now asserted that the Bank Examiner's and later the Clearing House Committee's appraisement of $1,500,000 for the Calumet property was largely due to the testimony of Columbus R. Cummings, who is the principal owner of the South Chicago City Railway Company, which traverses much the same suburban territory that the Calumet Company does. That is about the last kind of valuation to depend upon, we should think, and so far as we have had any opportunity to judge, the Calumet road has always struck us as a good piece of property likely to increase in value rather than be subject to permanent depreciation. If the real value of the property were in question, expert advice should have been sought outside the city—certainly not from interested parties within it.

Electric railways are many of them still in an interesting stage, but while there are pessimistic opinions in abundance, we wish to put on record our belief that for the vast majority of them, with their valuable franchises, large patronage, and the experimental work behind them, a period of hardening and rising quotations is at hand. The Chicago instance proves absolutely nothing to the contrary. There may have been bad banking and poor financiering, but that is no more an argument against electricity than it is against the universal relief following Mr. McKinley's election. Even in the brightest and best of times, bad management will result in disaster, and the finest climate on earth will not offset the wild dissipation of individuals.

THE TELEPHONE IN OUR HOMES.

THE telephone has long since come to be looked upon as an indispensable adjunct to every live business office and its value for purely commercial purposes is constantly growing as the number of subscribers to the various telephone exchanges increases. Of late, also, we are glad to note a marked increase in the number of private residences in which telephones have been installed, which would appear to indicate that for distinctly social purposes as well as for the business transactions of the household, the telephone is gradually meeting with fuller appreciation.

It seems, however, that there are still other fields open to it, which are well worth cultivating, at least in the larger cities. It has often been suggested that the theatres and concert halls might, so to speak, be brought to our firesides telephonically, and this is actually done in several cities abroad, although it has, we are sorry to say, never been carried out in this country. But even this proposition dwindles into insignificance in comparison with the domestic telephone enterprise which has been in highly successful operation in Buda Pest since 1892. This is nothing less than the "Telefon Hirmondo," or Telephone Journal, which at the present moment has no fewer than 6,000 subscribers. The scope of this enterprise will thus be seen to be of the widest possible nature. Its operation is conducted according to a regular programme on schedule time, beginning at 9:30 a. m., and continuing without interruption until 10:30 p. m. During this period the subscriber hears the daily news, stock quotations, theatrical and sporting news, reports of the parliamentary proceedings, fashion news, and the like. At 7 p. m. the overture at the opera house, or that at the Volkstheater, is sent over the wires. From 8:30 to 9:30 p. m., the regular concert of the "Telephone Journal" is given. On Thursday evenings from 6 to 6:45 a children's concert is given. There is also a special programme for Sundays, including a grand concert at 4:30 p. m. In addition to the regular force at the central exchange the most prominent authors read extracts from their works and artists perform in the concert room provided for that purpose at the exchange. The latest addition to this most perfect service is an alarm which calls the subscriber to the instrument when any communication of particular importance is to be sent out over the lines. But what is probably the most remarkable thing in connection with this enterprise is the extraordinarily low price at which the service is furnished, namely, $7.20 per year, or, say, two cents a day. It is hardly possible to hope for so low a rate as this in this country, but we are certain that a paying number of subscribers could be found in every one of our cities of over half a million inhabitants, who would willingly pay four times the amount stated above for a similarly organized service. The experiment is well worth trying, and we commend it once again to the attention of our telephone friends.

THE ANACONDA ELECTROLYTIC WORK.

THE annual report of the Anaconda copper mine just presented is very interesting from the fact that electrolysis plays so large a part in the work. This Montana property has exceeded 100,000,000 pounds of copper per year while the great Calumet and Hecla mine in the Lake Superior region shows up with but 90,000,000. On total receipts of $17,000,000 the Anaconda property shows a profit balance for the year of about $4,250,000, and is paying 10 per cent. on its present capital of $30,000,000. It appears that the refining plant can take care of 6,000,000 pounds of copper per month, or 3,000 tons. On a basis of 200 tons of refined copper per day, the copper would yield 350,000 ounces of silver per month and 1,500 ounces of gold; and it is noteworthy that the Anaconda property, in addition to its 107,000,000 pounds of copper is given credit in the report for 5,308,955 ounces of silver and 18,300 ounces of gold, which would represent about $3,500,000.

To disentangle all the figures of the report is impossible, but it may be said, broadly, that the working of the Anaconda property puts the gross copper cost at 11 cents per pound, and that the net cost is about 7½ cents. The Calumet and Hecla production still compares favorably with the Anaconda as to costs, but there is every indication in the report that the electrolytic methods recently introduced, to which we called attention last September, render possible a very economical and profitable handling of the great enterprise. A very slight advance in the price of copper, such as seems possible, would increase greatly the company's net revenue, one cent more per pound, meaning over a million dollars in additional income.

Telephony and Telegraphy.

MILITARY TELEGRAPH LINE FROM BISBEE TO SAN BERNARDINO, ARIZONA.

BY CAPTAIN W. A. GLASSFORD, U. S. SIGNAL CORPS.

THE running down of marauding Indians demands means of quick communication. The heliograph, or sun telegraph, in a sunshine region like Arizona, meets usual needs, especially when operations are over an extensive terrain and their field is continually changing. By sunflash signals the war with Geronimo was brought to a successful close. With signaling parties on prominent summits and a signalman with each moving body of troops it is easy to maintain an intercommunication which embraces every detachment.

The scene of the present Indian trouble is almost limited to the Chiricahua range, which runs south from Arizona along its eastern boundary into Mexico. These mountains are most rugged in character. The Indians can pass from Mexico along the highest ridges of this range quite unobserved, and make incursions far north of the Mexican boundary before information of their presence can be known without more speedy and permanent means of communication than heretofore existed. It was for this reason that the military telegraph line from Bisbee to San Bernardino, Arizona, was built. Cavalry and infantry, with Indian scouts, are now camped along the highest ridges of this range quite unobserved, and a band of Indians cannot get far before their trail is observed, and as soon as observed word is flashed or carried to the terminal telegraph station at San Bernardino, where the main camp of the troops is located.

From this point the military telegraph line connects with the commercial system of the country, which reaches all posts and department headquarters.

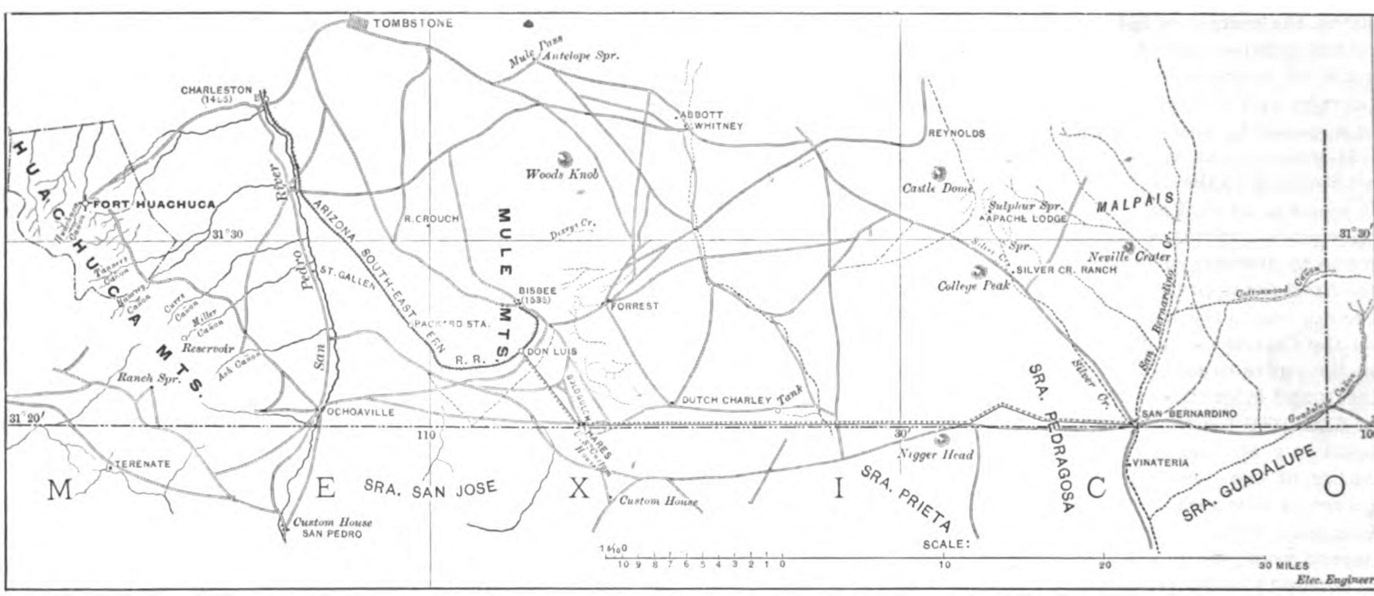
The matter of observing Indian trails is one of the most difficult problems the troops have to contend with; and really can only be satisfactorily done by Indian scouts enlisted in the service of the United States from the peaceful tribes. A band of hostiles crossing a rugged mountain over rocky cliffs generally leaves no marks that are observable to the eye of a soldier, but to the Indian scout the turning of a rock, or the disturbance of the slightest object on the ground, seems as an open book. He not only knows therefrom the time intervening between the disturbance of the object and the moment at which he observed it, but the number of the band and whether their movements were slow or rapid can be told.

The Signal Corps has, since 1873, maintained long stretches of military telegraph lines; but when commercial lines parallel them, usually along new railroads, the military lines give way, or, as frontier posts are abandoned, the military lines thereto are taken down. The post of Fort Stanton, New Mexico, near the Mescalero Apache Indian Reservation, was abandoned nearly a year ago, and the military telegraph line connecting that post with the railroad wires at Carthage and San Antonio, New Mexico—on the Santa Fé Railroad—was taken down and the material stored. Out of this material a new telegraph line was built this summer from Fort Grant to Mammoth, Ariz., to aid in intercepting hostile renegade Indians; and from the remaining material the line from Bisbee to San Bernardino, Ariz., has just been built. Military telegraph lines are built of tubular iron poles about 20 feet in length and nearly three inches in diameter, each weighing 72 pounds; ordinary No. 9 wire is also most frequently used.

Bisbee is situated in the Mule Mountains and is the location of the great Copper Queen mine (see map). The owners of the mine have a railroad, with telegraph line, 55 miles in length, to Benson on the Southern Pacific Railroad. The "Stilt City" as I have heard it called, would be a more appropriate name for Bisbee, for the town is built on the sides of a narrow canyon and the houses are upon terraces on the mountain sides, the front of many houses being held up by timbers where the slope sometimes is 30 degs.

The difficulty of approach for wagons to the railroad station at Bisbee made it advantageous to place the military wire on the poles of the railroad line, which was done to Don Luis station 4 miles from Bisbee down the mountain and outside the canyon. At Don Luis, therefore, the telegraph material was unloaded from the cars, to be carried thence by army wagons to its place of erection. From Don Luis there is a gradual downward slope to the Mexican boundary, and the telegraph line was built from that station to the U. S. Custom House on the Arizona-Mexico boundary in a direct line six and one-quarter miles. From the Custom House a direct line east, twenty-four miles in length, was built, parallel to and 200 yards north of the boundary monuments, which latter are placed along the United States-Mexican boundary at irregular intervals, several miles apart, but always so placed that the monument on either side of the one at which an observer stands is visible. This line of poles in perfect alignment passed almost due west over a spur of the Mule Mountains into the south end of the Sulphur Spring Valley; the end of this stretch of 24 miles of line being at the base of the Niggerhead Mountain, a conspicuous peak in the Swisshelm range. At the latter point the line had to make an angle so as to nearly follow the winding road which was made along the trail as we progressed through these mountains; and two additional curves were necessary as we emerged from those mountains. San Bernardino, which is only a very extensive cattle ranch, was then in sight, nine miles distant, and to that point another straight line of poles was erected. It will be seen that the line consists of 5 tangents, 2 angles and 2 curves; and is about 40 miles in length from Don Luis. Its erection was considerably retarded by unusually heavy rains which resulted in floods that made the trail impassable for our wagons; but, notwithstanding this, the line was entirely completed between the commencement of work on October 15, and November 10. The route of the line is shown on the accompanying map.

To erect such a line over such a country and transport the necessary material and supplies there were detached from troops at military posts 2 sergeants of the Signal Corps and 31 men, with one Indian scout for guide; also, two six-mule wagons, two four mule wagons and seven horses. The equipment of tools consisted of digging bars,



MAP SHOWING ROUTE OF U. S. MILITARY TELEGRAPH LINE, ARIZONA.

picks, shovels, axes, blasting material (as we occasionally had to use dynamite to blast holes for the poles), and the usual line working appliances. The detachment was divided into gangs for surveying and staking, digging holes and erecting poles, and stringing the wire. The bulk of the labor, such as the digging, was done by colored troops, who constitute the best possible force for doing work entailing hard manual labor. The effort was made to keep the gangs closely together; and if the work of one gang advanced more than that of another men were taken from the former and put with the gang which was falling behind. This enabled a constant personal supervision and oversight of the work of each party to be kept up by the officer in charge. Under a conjunction of favorable conditions there was erected in the lower Sulphur Springs Valley during one day five miles of completed line—the entire work of surveying the line, digging the holes, erecting the poles, etc., having been done that day. It should be remembered that over this stretch of country there was no road—only an occasional trail. As the work progressed, however, trimmers with axes advanced with the surveyors and cut a swath in the chapparal of sage brush and mesquite which covers the whole of Arizona. Our wagons in hauling and distributing the material along the line so trimmed out soon made a highway, which is now being used by troops, etc., traveling that way.

The want of water was one of the serious drawbacks, as streams or water holes are only found at long intervals. Kegs were supplied, and in these water was carried with the working parties as they progressed; and whenever far from a water supply dry camps had to be made dependence was had entirely upon water so carried. Ten ten-gallon kegs were available for this use. Under such circumstances not much was used for personal ablution.

In building this telegraph line it was deemed best to lay it out carefully, hence a surveyor's transit was used, and stakes set beside each point selected for placing each pole. The pole raisers by setting the poles accurately on the line of stakes were able to preserve a perfect alignment. By such long tangents and perfect adjustment to a straight line, as the poles could be thus placed farther apart, there resulted an economy in material; and, as there is less strain on a line when it is straight, there will be less chance of interruption in the working of the line. The latter is an important feature where a line passes through stretches of uninhabited country.

The wire for this line having been before used, and in taking down the old line the wire having been coiled in bundles of different sizes, it was found that the collapsible reel known as the "Little Giant" was of great availability in that particular feature, as it is capable of handling coils of varying diameter. In this matter of the reel there is an illustration of the peculiar fact of the frequent development by different persons of a similar idea or invention. When the line between Fort Stanton and Carthage was about to be taken down, the necessity of a collapsible reel appealed to the writer, who set to work to design one. One day while the reel so designed was being constructed, on going into a hardware store to purchase some bolts there was found the advertisement and picture of the "Little Giant" reel. Its similarity to the writer's design was remarkable—it was almost identical.

There was used for boring pole holes another device, entirely new, as far as known. It consisted of a hardened steel cone 6 inches long from apex to base, the base being 3 inches in diameter—a trifle larger than the diameter of the iron poles; screw flanges of a boring bit similar to those on the point of an auger were made upon the cone surface. Into the base of the cone was fastened an iron bar about 4 feet long, at the end of which bar was placed a handle similar to that of an auger. In ground devoid of gravel, this ground-boring-bit could be screwed down into the earth, and the soil, instead of coming up as in the case of an ordinary auger, was compressed all around the hole as the auger bit was driven down. Holes thus made would receive the pole snugly, and the compression of the soil under the ground served to make the pole firm and much more stable than when the hole was dug and then the loose earth thrown in and tamped. In some soils such a boring bit would be invaluable for such work, for a hole can be made in a short time with a minimum of labor.

These military telegraph lines serve an important purpose not only in aiding to prevent marauding raids of Indians but also as a means of promoting the business interests of the sections through which these lines run, as a channel of quick and cheap communication. It is the policy of the Signal Corps to charge only a nominal rate for business telegrams, consequently a great impetus to settlement, and to mining interests, has frequently been given thereby.

CHICAGO, ILL.—Electric power for drawbridges is to be adopted for all the bridges over the Chicago River at Chicago, replacing the steam plants now required for each bridge.

NEW ELECTRIC BELL BUOY IN BOSTON HARBOR.

THE risks attending the navigation of vessels in and out of Boston Harbor have long been known to mariners, and this was emphasized in a startling manner by the disaster which occurred to the big freight steamer "Venetian," belonging to the Leyland Line, which, on leaving the harbor on Saturday, March 13, 1895, ran on State Ledge and broke in two amidships, entailing a loss of something like $385,000,

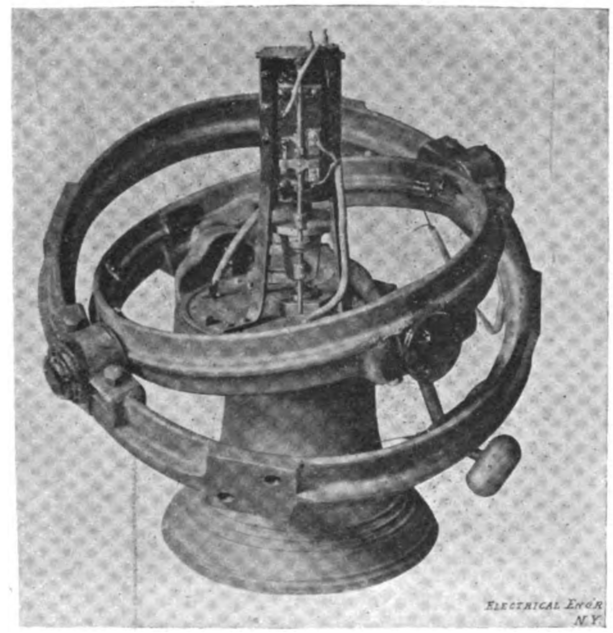


Fig. 1.—Electric Bell Buoy, Boston Harbor.

and imperilling navigation from that date until now, for the last of her has not yet been removed.

This and other mishaps of lesser magnitude prompted more than one inventor to solve the problem of rendering navigation safe at all times and under all conditions. And it would appear that the problem is in process of immediate solution, even if it has not already been solved, by an electrical inven-

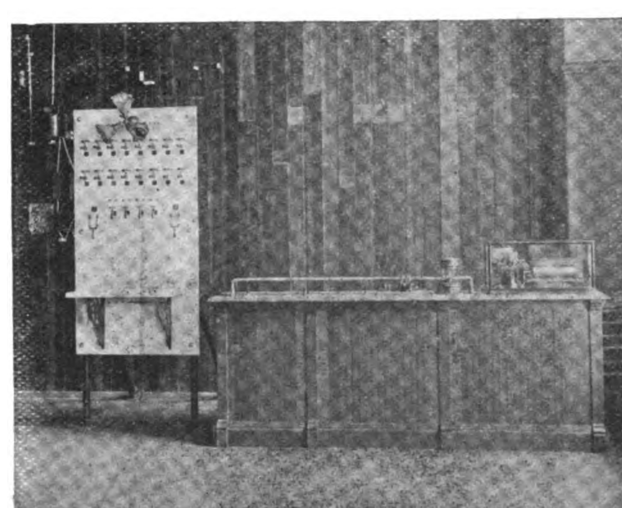

Fig. 2.—Electric Buoy, Central Station, Boston Harbor.

tion, due to Mr. John A. Fairbanks. The apparatus is being developed and installed by the Fairbanks Electric Bell Buoy Company, the perfecting and building of the whole having been entrusted to Messrs. Murdock & Faber, the well known telephone engineers of Boston.

For over a year the work has been in progress, and having been completed, the Federal Government has granted permission to place three of these electric bell buoys at different

points along the deep water channel in Boston Harbor, all of which are operated from Castle Island, now used as one of the city parks. These buoys have been anchored as follows: At Nixey's Mate, 3¼ nautical miles; State Ledge, ¾ mile; and Upper Middle Ground, 1 mile from the operating station. A 500 volt current is used, and this is taken from the arc light circuit with which the Boston Electric Light Company illuminates Castle Island.

For conveying the current from the island to the buoys and return, a cable made by the Safety Insulated Wire and Cable Company, of New York, is used. The cable is of the following construction: Three conductors, each composed of seven strands, equaling No. 12 B. & S. gauge, having an outside diameter of about .33 of an inch, with an insulation resistance of 800 megohms per mile. These conductors have a double covering of jute, over which is a heavy steel armor.

Besides the many difficulties to be contended with in the construction of the apparatus, there was a further important matter to be dealt with. The bell might be struck regularly and perform its function accurately under all conditions, yet how to render it even more efficient and trustworthy, helpful to mariners navigating their ships to and fro, and at the same time automatically recording its own operations for reference in case of an emergency (?). This has all been provided for, so that every blow struck by the electrically operated hammer on the bell is unerringly recorded in the station in Castle Island.

To aid our readers in arriving at a clear understanding of the principles according to which this useful piece of apparatus has been constructed, we illustrate the bell, and also the operating room on Castle Island.

Fig. 1 shows the bell as it is hung on an universal joint. The magnet also is shown. This consists of an iron clad solenoid and plunger on the lower end of which is a soft iron disc of exactly the same diameter as the iron case. On the bottom of the disc is a forked composition casting, through which passes one end of the hammer lever, which is also forked. This works on a roller bearing. To the bottom of the under tine or prong is fastened a flat spring of phosphor bronze which curves over the end and lies parallel to, but not touching, the top side of the tine and into a slot in the shank. This spring gives the rebound to the hammer and allows of a clear ringing tone from the bell. On the long arm of the lever is a 2¼-pound hammer, the bell itself weighing 100 pounds.

On the side of the magnet may be seen a switch, the various parts of which are made of phosphor bronze, the purpose of the switch being to shunt the current from the lower conductor to the upper one, which is connected to the registering device at the shore end of the circuit. The plunger of the solenoid is protected against rusting by a thin brass tube which is slid into place while hot and afterwards trued up in a lathe. The other parts, which are made of iron, are heavily plated, and where it is practicable, painted and covered with vaseline, while a dome of cast iron—not shown—covers the whole and is held down to a gasket on the bed plate by four bolts.

The buoys that have thus been electrically equipped are of what is known as the 2d class gas buoy type, that being the most stable type for a rough sea. This type of buoy is conical in shape, the apex being cut off at a point where the diameter is about 30 inches. Four upright standards of channel iron support the bell. Near the top and on one side of the buoy is a manhole.

From the center of the base extends an iron pipe of considerable diameter which supports a two-ton weight to keep the buoy in an upright position. This weight, or anchor, has a 2½-inch hole through its entire length, and at its upper end a pipe of the same size is screwed in and extended up to the top of the buoy, where it enters a junction box. This junction box is a rectangular casting having two chambers separated by a wall of iron, and securely bolted to the under side of the plate which forms the top of the buoy.

One of the spaces in the box is the outlet of the pipe through which the cable is brought in. The other space is used to make the splices connecting the cable to the wiring of the bell. These wires pass through a small box and up one of the standards to the outside ring, where they pass through the center of the trunnion by means of a switch to the inside ring, and thence inside the dome by a second switch.

These switches are made of phosphor bronze mounted on hard rubber covered by a cap to keep out water. The cable passes through the large weight and pipe to the junction box, where it is held by a clamp made in two pieces secured together by four bolts.

The ends of the armor are left long and turned down around the sides of the clamp and bent into a groove and held there by a second clamp of wrought iron.

The current is distributed to the three buoys from a marble switchboard, shown in Fig. 2. One side of the circuit is connected with the drum of the circuit breaker and as contact is made continues out to the magnet and returns through the lower blade of the switch and conductor connected thereto; but as the current energizes the magnet and completes the stroke of the hammer on the bell, the switch operates and sends the current through the other conductor and registering magnet, which indicates and records the blow on a paper ribbon as it feeds along. The amount of current used in striking a blow and running the motor is 1.4 amperes.

A one-eighth horse-power electric motor of the Holtzer-Cabot type is connected to the circuit breaker by means of worm gears, whereby the speed is reduced from 1,500 revolutions to one per minute. This motor also operates the paper feeding device by means of a shaft running under the cabinet. Alongside the motor is a time stamp which records automatically the minute, hour, day, week, month and year; also the words, "tested," "started," "stopped." etc., on the paper, so that a complete and permanent record is thus kept for future reference.

The buoy being regulated to strike various combinations or groups of strokes, at stated intervals, pilots and captains may discover their exact location and promptly get their bearings for the next buoy.

SIGNALS FROM MARS.

Sir Francis Galton declares in an article in the London "Fortnightly Review" that somebody on the planet Mars is signaling to us by means of dots and dashes of light, produced by something like heliographs. It is a pretty good yarn, and only the name of the distinguished English scientist gives it a sober aspect.

It is said that one of the great European observatories prepares a recording apparatus, which is found to perform its mission effectively. A long strip of telegraph paper is slowly drawn by clockwork under a hinged pencil, on which the observer rests his finger. When the scintillation or flash is on he presses with his finger and the pencil leaves a mark. When the flash is off, he ceases to press, a spring lifts the pencil and a blank is left on the traveling slip of paper.

An examination of these telegraphic ribbons shows that three, and only three, different signals are employed by the Martian operators, who are now working splendidly under an uncommonly intelligent director of works.

These signals differ only in their lengths and resemble the dots and dashes of the telegraphic code.

The dot lasts one second and a quarter. The dash lasts two seconds and a half. The line, or longest dash, lasts five seconds.

After a few well marked succession of dots, dashes and lines it is ascertained that the interval between letters is one second and a half, the interval between words three seconds and the interval between paragraphs six seconds.

As there are only three varieties of signals, the total number of different words of one letter is three, of two letters nine, of three letters twenty-seven, of four letters eighty-one, of five letters 243 and so on in geometrical progression. The average time occupied in signalling these words, including the three seconds pause at the end of each, are six, ten, fifteen, twenty and twenty-four seconds respectively. The Mars folk evidently intend to speak to us in very terse and pointed language.

YOUNGSTOWN, O.—The local telephone service of the Central Union Telephone Co. is being very much improved, and Mr. W. W. Johnston, the manager, says that $40,000 will be spent in improvements. The exchange has 700 subscribers and is adding accommodation for 600 more, of whom 164 have been secured.

THE SOUTH BEND, IND., TELEPHONE COMPANY publishes in a local paper its full list of over 500 subscribers. It has a 20-year franchise with restrictions as to rates, etc. The system is metallic circuit and the instruments are Stromberg-Carlson long-distance type.

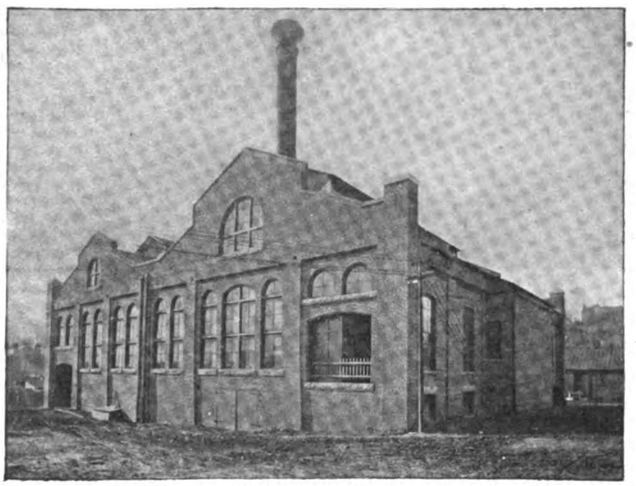
THE POSTAL TELEGRAPH COMPANY has been preparing for the Smithsonian Institution the telegraphic apparatus furnished by it to Mr. Edison and Mr. E. D. Adams for the message around the world at the recent Electrical Exhibition. The Smithsonian has secured other apparatus relating to features of that memorable show of historical and modern apparatus.

MORRIS PLAINS, N. J.—The hospital has put in a telephone system with switchboard and forty-two stations, the board being located in the office of the institution.

Electric Transportation.

THE RICHMOND TRACTION CO'S RAILWAY SYSTEM.

RICHMOND, Va. is now generally looked upon as the place where electric railroading on the modern extended scale was first practically and commercially demonstrated. Many important details of electric railway work were there first

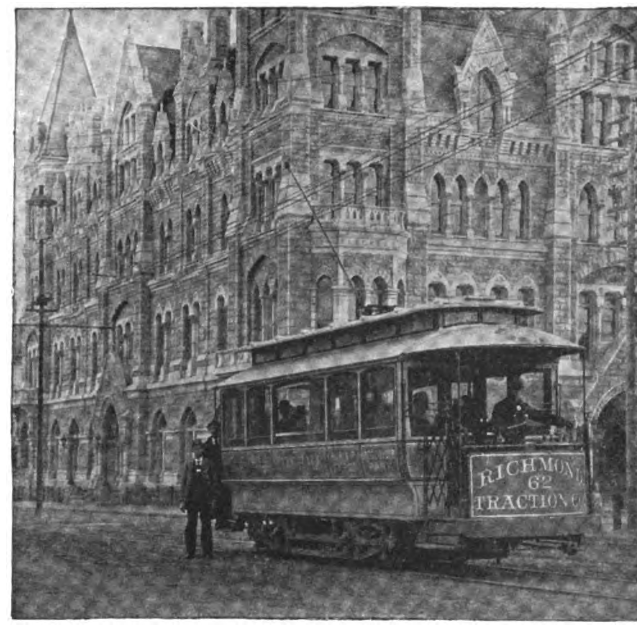


Power House, Richmond Traction Co.

called into life and many of them are still standard practice. To those who recall the first Sprague road there, the description of the latest electric railway system there, that of the Richmond Traction Company, will be of more than usual interest.

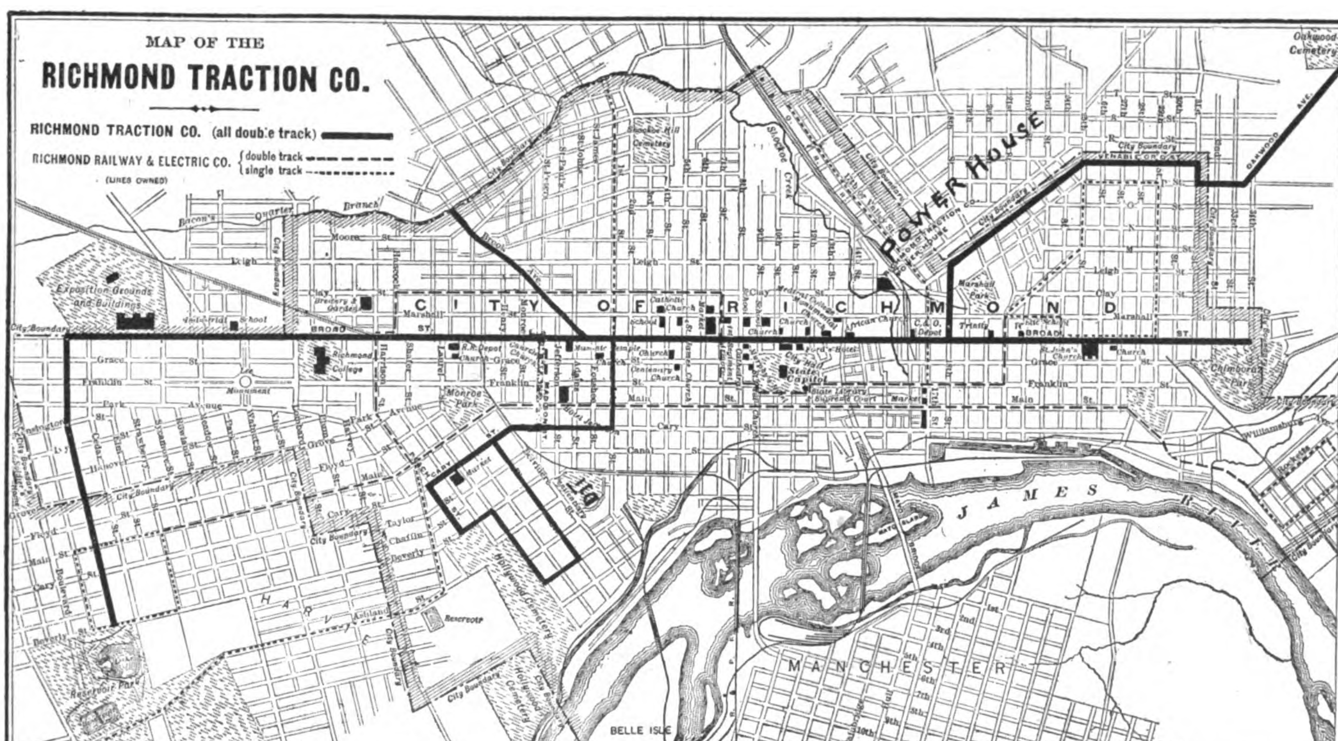
THE ROUTE.

The main line of the road extends from east to west, the full length of Broad street, the widest street and principal thoroughfare of the city. It connects the two sections of the city, the east and west ends, which are separated by a broad, deep valley, where the only grades of any consequence exist. On the east slope the grade is about 1,500 feet long and is on an average 8 per cent., except for about 300 feet, where it is 10 $^5/_{10}$ per cent. On the west side it is about the same length and averages 9 per cent. The branch line from Eighteenth and Broad streets, extending to Oakwood Cemetery, is about one and one-half miles long. Another branch line now under construction, from First and Broad street, south and west to Hollywood Cemetery, is about one and one-half miles long; another branch through Brook avenue to the city limits will shortly be built. When the branches are completed there will



Car of the Richmond Traction Co.

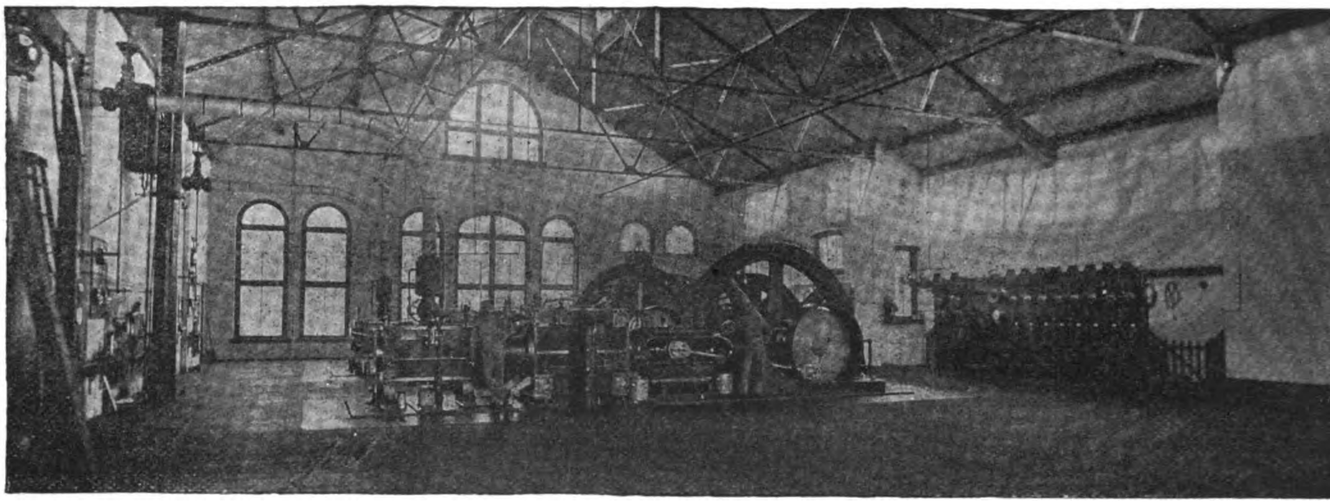
be about 15 miles of track. The accompanying map shows the route of the existing lines in Richmond.



Tracks of the Richmond Traction Co.

TRACK.

The rails are 95 pounds, groove, girder, furnished by the Johnson Co. The cross ties are 6 by 8, 7 feet long, white oak, spaced 2½ feet between centers. The track on all paved streets is laid in concrete, 6 inches under tie, and to the top of the same. The space between the web of the rail is filled with concrete, which method of construction was required by

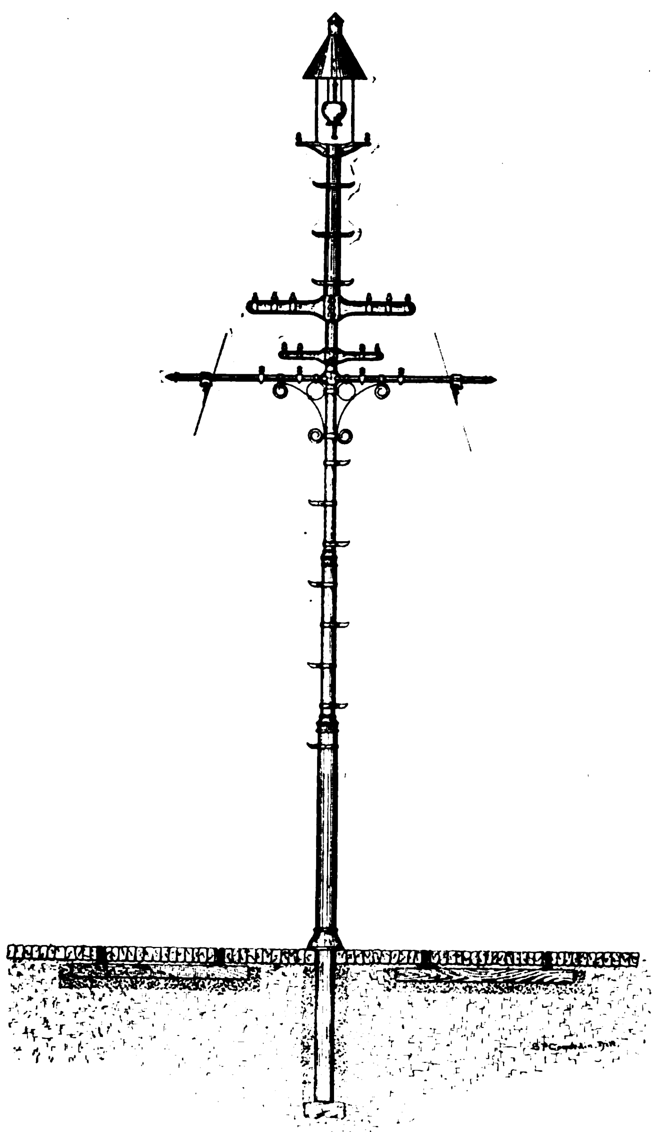


INTERIOR OF POWER HOUSE, RICHMOND TRACTION CO.

the city ordinance. The Johnston rail bond which was recently awarded the John Scott Medal by the city of Philadelphia through the Franklin Institute, is used.

OVERHEAD CONSTRUCTION.

The overhead construction is very neat and ornamental, and



RICHMOND TRACTION CENTER POLE WITH ARC LAMP.

on account of the width of Broad street (120 feet) center pole construction is principally used, the tracks being spaced 8 feet between the inside rails. At the intersection of the streets the center pole is used also as an electric light pole, as is shown by the accompanying engravings. No. 0 trolley wire and No. 00 to 0000 feed, furnished by Roebling, is used; the overhead material was furnished by the Ohio Brass Co. The Walker mechanical clip is used throughout.

CARS.

There are 26 summer cars of the American Car Company and 22 closed cars, furnished by the Stephenson Company, and the St. Louis Car Company. They have recently added two extra handsome single revolving seat cars, made by the American Car Company and which are very popular; the Peckham trucks and New Haven double car registers are used.

Each car is equipped with two 1,000 General Electric motors; this large size was selected on account of the heavy

A. L. JOHNSTON.

grades, and has proved very successful and up to the present time not a single armature has been burnt out.

POWER HOUSE.

This is situated in the valley, at the bottom of the grade, a short distance off the line, as shown by the map. It is a solid brick building, fireproof with an iron truss roof covered with slate. It contains two 250 horse-power compound condensing Hamilton-Corliss engines, speeded to 100 revolutions per minute, direct connected to 300 kilowatt General Electric multipolar generator. Steam is furnished by two 300 horse-power Campbell & Zell water tube safety boilers, in separate batteries. Deane condensers and Worthington pumps are used. The General Electric standard generator and feeder panels are used, with a center panel containing a recording wattmeter, volt and amperemeter.

CAR HOUSE.

The car house is situated at the west end of the road, near the reservoir park, and is a fireproof building, large enough for about 80 cars, the rear of the car house is partitioned off for the repair shop.

Construction was commenced in November, 1895, and the road put in operation June 20, 1896, in time for the Confederate Veterans' Reunion, and 45,000 passengers were carried daily for a week without a hitch or accident of any kind. The officers of the company are: John S. Williams, president; W. M. Habliston, vice-president and general manager; R. Lancaster Williams, treasurer; Addison Cook, auditor; E. J. Willis, superintendent. During the construction, Mr. A. Langstaff Johnston was consulting engineer, with S. P. Cowardin as assistant in charge of track construction, and R. P. King in charge of overhead construction; Jas. F. Bradley, of Manchester, Va., was the general contractor for the laying of tracks. In 1889, Mr. Johnston built the Rich. and Seven Pines Electric Railway, extending to the battlefields about Richmond. In 1890 he built the Richmond and South Side Electric Railway and laid out, in connection with the railway, Woodland Heights and Forest Hill Park.

He has since that time constructed the New Orleans and Carrollton Railway, 20 miles in length, the first electrically operated road in New Orleans. After the completion of this work he accepted a position with the Hestonville, Mantua and Fairmount Passenger Railroad Company, one of the oldest car lines in Philadelphia. The electrical equipment of the system was begun in 1893 in conformity to the plans of Mr. Johnston, which embodied many features of mechanical and electric interest. He also constructed the Fairmount Park and Haddington Railway, now part of the Hestonville system. The Norfolk and Ocean View Railway, at Norfolk, Va., was changed from steam to electricity in 1895 by him.

Mr. Johnston has won distinction by the invention of a number of ingenious devices which are now well known in street railway practice, and was recently awarded by the city of Philadelphia through the Franklin Institute, the John Scott medal of merit for his method of bonding rails.

Mr. Johnston is a member of the American Institute of Electrical Engineers, the American Society of Civil Engineers, and the Franklin Institute.

Mr. Johnston has been a prominent street railway engineer ever since the practicability of applying electricity as a motive power was conclusively demonstrated by the successful operation of the Richmond and Union Passenger Railway in 1887. The work of drawing up the plans of the difficult track work, etc., was intrusted to Mr. Johnston, by Mr. Sprague, and his reputation as a skillful street railway engineer has dated from the successful completion of that pioneer railway installation. Since that time he has been continuously engaged in the street railway field.

FIGURES OF LIVERPOOL ELECTRIC ELEVATED.

The passengers carried by the Liverpool (England) elevated railroad in the year which ended in June was 7,519,950, against 7,101,430 the preceding year. The road issues first and second class and workmen's tickets. In the last half year less than one-eighth of the passengers traveled first class, and 27 per cent. traveled on workmen's tickets. Dividends have been paid in successive half years at the rate of 2, 2¼, 3½ and 2¾ per cent., successively.

MR. EMIL KOLBEN, chief engineer of the Oerlikon Works, Switzerland, has resigned his position.

HENRY'S SINGLE WIRE DOUBLE TRACK ELECTRIC RAILWAY SYSTEM.

NOTWITHSTANDING the magnificent record made by the overhead wire electric railway whose growth has been without a parallel in the arts, it is a fact that cannot be disguised that in the opinion of many the exposed street constructions in the way of poles and wires should be dispensed with. The opinion is so strong in certain congested districts that the railway companies are seriously hampered, and are unable to furnish as efficient a service as the more sparsely settled portions enjoy. To meet those objections without sacrificing any of the well-known advantages of the trolley system is the main object of a plan recently brought out by Mr. John C. Henry, of Denver, Colo. The construction referred to meets the opposition half way by dispensing with one-half of the poles and wires commonly used.

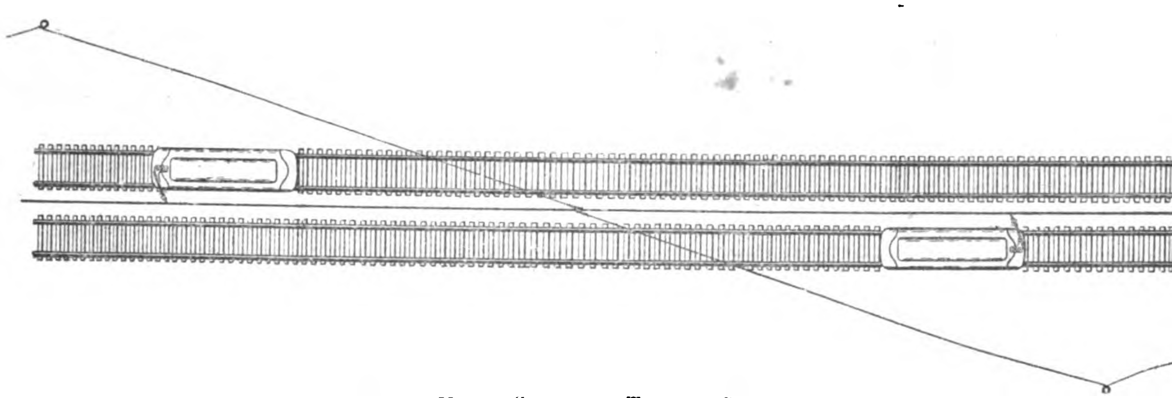


FIG. 1.—HENRY SYSTEM OF TROLLEY SUSPENSION.

In Figs. 1 and 2 is shown Mr. Henry's system of double track electric railway with the cars traveling in opposite directions and making contact against the sides of a single trolley wire which in this case is suspended between the double tracks from span wires at the usual height. The poles, instead of being located opposite each other, are staggered and occupy diagonal positions on opposite sides of the street, so that one-half of the number ordinarily used may be dispensed with and the strain on the remainder greatly reduced.

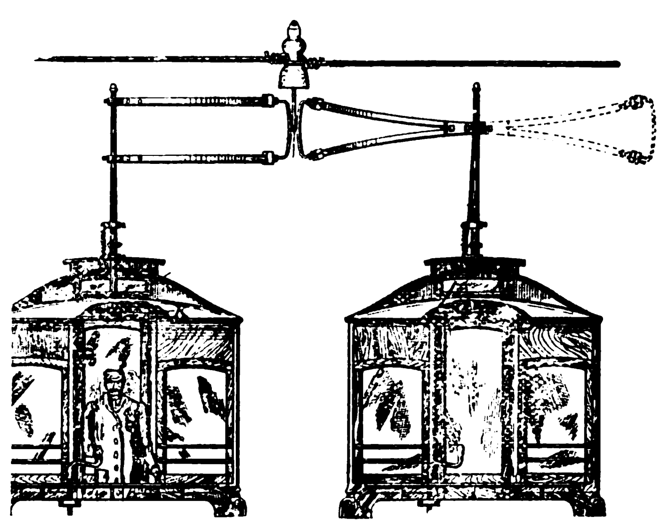

FIG. 2.—HENRY SIDE CONTACT TROLLEY SYSTEM.

In the construction shown the span wire strain is exerted in two directions on each pole, namely, laterally, and in a line parallel with the track, the latter component being comparatively small. With poles spaced, say, 200 feet apart, on opposite sides of a street, 50 feet between the curbs, the lateral strain on the pole is only one-half as much as the pull at right angles thereto (parallel with the track), and the lateral pull is a balanced one. The fact that but one trolley wire is used for both tracks is also a relief to the poles.

Fig. 2 shows a pair of trolleys mounted on cars on opposite tracks in engagement with the sides of the same trolley wire. It will be observed that the trolley is somewhat similar in

form to those used by the Siemens and Halske Company, in Europe and recently improved upon in this country, excepting that the Henry trolley is held laterally in a trailing position against the side of the wire. Further details of construction show the trolley to be under the control of the motorman from either end of the car.

ELECTRIC LIGHT AND POWER ON THE B. & O.

SOME very important additions are being made to the power and lighting plants along the line of the B. & O. Railroad. Mr. W. D. Young, superintendent of electrical construction, is giving his personal supervision to most of the work. The improvements in the Baltimore Belt Line power house are being rapidly pushed to completon. The foundaton is now being built for a 650 horse-power Greene-Corliss engine, direct coupled to a General Electric 500 kilowatt power generator. This is the fifth engine of this type to be erected in this powerhouse, and will add greatly to the power plant. It will be used in pulling the trains through the tunnel as well as in the general power work of the station. It will be remembered that in addition to furnishing the power for the Baltimore Belt Line tunnel motors, this plant also operates about 180 street cars of the Baltimore Traction Company and several small motors that are used by the railroad in switching cars at ferry slips. The total capacty of the power plant wil be 3,150 horse-power when the new engine is installed and it is expected that it will be in working order by the middle of January.

In the lighting plant, which is in the same station with the power plant, there is being erected a 250 horse-power Armington-Sims engine, belt coupled to one 150 kilowatt General Electric generator. Mr. Young is also replacing two 120 kilowatt alternating generators by two 150 kilowatt A. N. General Electric generators. The lighting plant now has a capacity of 1,150 horse-power and furnishes the current for the lights at Locust Point, all the Baltimore yards, Camden Station and numerous ferry slips and freight houses, besides lighting the tunnel and the Mount Royal passenger station. There has just been installed in this plant a Van Dresser automatic oiling system at a cost of about $3,600 by which all bearings on the engines and dynamos are automatically lubricated, saving the expense of six men.

In the boiler room there has been erected a C. W. Hunt coal and ash conveying apparatus which takes the coal from the dump to an overhead bin from which it is to lead immediately in front of the furnace doors, thus facilitating very greatly the work of the firemen. The buckets that handle the coal, are also arranged in such a way as to convey the ashes to the bin outside the boiler room where they are deposited automatically.

A repair shop has been fitted up in one end of the power house and Mr. Young has ordered and expects to receive in a few days the machinery necessary for the shop. This will consist of one field winding lathe, one engine lathe and drill press, several high speed lathes and the necessary testing machines, etc.

The electrical department of the B. & O. is now growing at a very rapid rate. The public has but a slight idea of the extent of the electrical plants. At Zanesville there is a 50-arc light plant which is to be increased to 75. It is contemplated to erect a lighting station at Philadelphia of 75-arc light capacity to light the stations, yards, piers, warehouses and platforms. The installation of this plant, if it is decided upon, will result in quite a saving to the company. At Benwood the lighting station will be made of sufficient power to light all the yards and shops at that point and also the company's property at Bellaire and Wheeling, a total of about 100 arc lights. The plant at Newark, O., which has a capacity of 30 arc lights, will be enlarged to 50. The improvements that are being made at Cumberland will require an extension at that point from 50 to 75 lights. At Garrett, Ind., the plant has been temporarily suspended, but it will be started up again soon. The Mount Clare plant, which has a capacity of 30 lights, will be discontinued and the power will come from the Baltimore plant. At Brunswick the extensive yard improvements will require 25 more arc lights making a total of 75 at that point. The other lighting plants of the road are at Washington, Grafton, West Va., Deer Park, Pittsburg and Chicago Junction.

FROM ONE OF THE COLLEGES.

"I cannot renew my subscription without expressing my appreciation of the excellence of your publication, and the many interesting features it possesses. Although I endeavor to read all current electrical literature, I find more pleasure in devouring the numerous good things contained in "The Electrical Engineer, than in perusing other periodicals. May your well-deserved success continue."

TRACTION TROUBLES IN TOLEDO.

A special dispatch from Toledo, O., of Dec. 14, says: There is a pretty fight on here between the first mortgage bondholders of the Toledo Electric Company on one side, and the Toledo Traction Company on the other, in which Eastern and Chicago capitalists are deeply interested. The move of the Traction Company to float nearly $3,000,000 of bonds in the East brought a representative of the first mortgage bondholders here to-day to press action for the appointment of a receiver for the Electric Company and an injunction restraining the Traction Company from using appliances of the General Electric Company here. A few weeks ago the stock in the Toledo Electric Company was sold to New York parties, who sold it to Ream & Hale, of Chicago, principal owners of the Traction Company. The bondholders were not consulted, and are now fighting to save the property back of the bonds. An injunction has already been granted, a motion for the appointment of a receiver filed, and now the bondholders, principally Boston men, are waiting for the court. The hearing will be held as quickly as it can be pressed.

RENO ELECTRIC STAIRS ON BROOKLYN BRIDGE.

The Reno traveling stairway has been given a trial at the New York end of the Brooklyn Bridge. The system has already been described frequently in the papers. Passengers stand on the incline in single file and are carried along and up as the flooring moves. The steel treads form an endless mat that assures firm footing. They stay there until left on the comb-shaped iron grating on the top platform. The grating is so fitted that nothing can catch, and no accident is possible. The handrail is a chain of steel links run by sprocket wheels and thickly covered with rubber. It moves uniformly with the endless footpath.

The experiment was run by an electric motor with the same electric current that was operating the bridge cars. Only a little increased current will be necessary to work the machinery when the entire system is in order. The capacity of the inclined elevator is put at 3,000 passengers an hour. The elevator was on exhibition at Coney Island last summer, and it is said carried 75,000 passengers without an accident.

THE BRIGHTON-ROTTINGDEAN ROAD, which operates across a short stretch of the deep water beach at Brighton, England, has, it is reported by cable, been washed away in a heavy gale. This probably refers to part of the trolley line, as the track was solidly laid.

ONE HUNDRED THOUSAND HORSES running wild, because electric cars and bicycles have cut them out of occupation, are proving a pest in Washington State, and the farmers are hoping for a hard winter to kill them off. This fall whole bands of them have been sold for one or two dollars apiece.

THE STREET RAILWAY REVIEW, of Chicago, beginning with January, 1897, will issue a foreign edition, the publication of which for the present will be quarterly. It will be given a wide circulation all over the world, and it is needless to add that it will be full of valuable and interesting matter. Messrs. Windsor & Kenfield have our best wishes for the success of their timely and deserving enterprise.

BROOKLYN, N. Y.—There was a serious blockade on the Brooklyn Bridge on Tuesday evening, Dec. 15, at the time when travel was the heaviest. Since the substitution of electric motors for steam locomotives the Bridge Trustees have obtained the propelling power from a station on Kent avenue, Brooklyn, which is supplied with four powerful engines. At 5:30 P. M. the crosshead of one of these broke, and the motive power for the bridge cars was materially reduced. The annual report of the Bridge Trustees, issued last week, speaks very favorably of the results with electric traction there. The traffic last year fell off a few hundred thousand passengers.

MINNEAPOLIS, MINN.—Work is proceeding satisfactorily on the massive new dam of the St. Anthony Falls Power Co. in the Mississippi River at Minneapolis. The Twin City Rapid Transit Company will utilize the power obtained from the new dam—estimated to be 10,000 horse-power—and transmit it electrically. The St. Anthony Company will install 10 horizontal turbines of 1,000 horse-power each; and these will be directly connected to a like number of alternating current generators by the Twin City Company, which leases the power at the water wheels. The electrically transmitted power will be used to operate the cars on the extensive electric railway system of St. Paul and Minneapolis by means of rotary transformers.

Society and Club Notes.

FEATURES OF THE GAS EXPOSITION.

Among the popularly interesting pieces at the Gas Exposition to be held in this city, in January, 1897, will be a tower of gas and glass and iron, which will stand in the center of the hall, designed and built by Louis Tiffany of New York, the creator of the celebrated Tiffany chapel shown at the World's Fair. As a show piece the tower will far surpass the chapel in brilliancy, as in size. It will be sixty feet in height, with a diameter of twenty feet at its base. The design of the tower is that of a cathedral altar. Superimposed, one upon the other, its graceful and multi-colored columns will rise to a pinnacle capped by a ball of fire. Over 3,000 open jets will glow and glisten from its countless prisms, and spaced here and there, row after row of incandescent gas lamps will add to the brilliancy of the effect. The tower will be made of pieces of glass of every conceivable color, blending and shading, from base to pinnacle, in all the hues of the rainbow. Just short of the apex a fountain of water will be playing, to be caught in a basin and disappear to reissue again several sections below. To accentuate the color effect, columns of steam will be driven up through the tower, cooling and condensing as they rise and forming thousands of water prisms on their sides.

The cost of the tower will probably exceed $35,000, and it is designed not merely for exhibition at this time, but as the contribution of the American gas interests to the Paris World's Fair of 1900. It will in itself constitute a powerful attraction, and, coming as it does, from almost the single artistic genius who, in the world of contemporary art, has made a distinct name and place for America, it will possess a unique interest.

AMERICAN FEDERATION OF LABOR.

At the Cincinnati convention of the American Federation of Labor, the Committee on Reorganization recommended that the National Association of Electrical Workers be granted affiliation and the co-operation of the American Federation of Labor in the work of organization, and the recommendation was concurred in.

Reports of Companies.

STATEMENT OF THE E. S. GREELEY & CO.

We have received from Messrs. E. S. Greeley and J. W. Sands, receivers of the E. S. Greeley & Co., the subjoined statement of the assets and liabilities of that concern:

ASSETS.

Store Stock—		
Inventory value	$59,735.36	
Estimated cash value		$44,801.00
Office and store furniture and fixtures	1,500.00	750.00
Shop stock, machinery, tools, etc.—		
Inventory value	21,253.05	
Estimated cash value		13,000.00
Laboratory stock, tools, etc.—		
Inventory value	5,835.22	
Estimated cash value		3,000.00
Accounts receivable.—		
Nominal value	96,700.84	
Estimated actual value		70,000.00
	$185,024.47	$131,551.00

LIABILITIES.

Accounts payable	$102,044.40
Bills payable	72,022.92
	$174,067.32

RECEIVER FOR THE SYRACUSE STORAGE BATTERY CO.

The Syracuse Storage Battery Company went into the hands of a receiver on Dec. 21 on the application of a majority of its directors. L. H. Groesbeck was appointed by Judge Hiscock, to whom the matter was presented, and will give a bond of $10,000. The directors all joined in the application. The papers show that the company, whose factory is in Phœnix, with the main office in Syracuse, has not sufficient capital at its command to continue operations. It is set forth that the liabilities amount to about $40,000, while the assets, consisting principally of patents, are assumed to be worth $30,000. The officers and directors are Riley V. Miller, president; Thomas Hooker, vice-president; Charles L. Pack, secretary and treasurer; Jacob Amos, H. L. Loomis and Ray B. Smith, directors.

The company operated under its own patents and also under a license from the Storage Battery Company of Philadelphia, Pa. It employed about thirty men.

IMPORTANT NEW WORK OF THE BROOKLYN EDISON CO.

Contracts have been signed for the sale to the Edison Electric Illuminating Co., of Brooklyn, of one of the most valuable shore front properties in Brooklyn. The price is placed at about $260,000. The property adjoins the piers of the Long Island Railroad Company at Sixty-sixth street. It is 260x1150 feet, giving a water frontage of 260 feet, with rights to 550 feet under water and 600 feet back of the bulkhead, taking half of the block from the water front to First avenue.

Mr. Peabody, the secretary and treasurer of the Edison company, says of this purchase and of the intention of the Edison company: "It is the intention of the Edison company of Brooklyn, as soon as the weather permits, to construct a steam plant for generating electricity of an aggregate capacity of 20,000 horse-power, which will probably be the most economically appointed plant of its kind in the world. There will be erected a one-story brick building 260x250 feet, which will have two rooms, a boiler and an engine room, the cost of which will be $300,000. This plant will be one of the best equipped stations in the country, and will put Brooklyn ahead of all other cities in the manufacture of electricity. The system will be underground, doing away with the overhead wires, as far as possible, and we expect to reach far into Long Island. We expect to be able to furnish current from this plant as far as Babylon on the south side of Long Island, Roslyn on the north and Garden City and Hempstead in the center. The whole system will be regulated by meter, both for lighting and power. Our system is perfectly insulated and the loss of power is almost nothing. With a large production of current the cost decreases and an average reduction to consumers will be the natural outcome."

Legal Notes.

MAYOR SWIFT'S VETO OF THE FOUR-CENT CHICAGO FARE ORDINANCE.

In his veto, on Dec. 22, of the four-cent street car fare ordinance, which had been sustained by the Chicago City Council by a vote of 20 to 47, Mayor Swift said that if he signed the measure he would place the city in the doubtful position of having consented to violate what the street car companies had accepted in good faith as a contract. These contracts stated that the fare should be five cents, and besides, the Mayor declared, there was no public demand for a cheaper street car fare.

A large number of street car employés whose wages were threatened with reduction, were in the galleries and wildly applauded every speech made against the ordinance, and when Mayor Swift read his measure constantly interrupted him with cheers.

RIGHT TO CUT DOWN TREES.

—The case of the Commonwealth of Philadelphia vs. Clark, affirmed by the Superior Court in an appeal from the decision of the Berks Court, is a case involving the right of telegraph and telephone companies cutting down trees for their lines. The defendants were employés of the American Telephone and Telegraph Company, and while stringing wires through the Schuylkill Valley they cut down a number of ornamental trees on the property of Mr. John Marshall, of the University of Pennsylvania, near Douglassville. It was contended that more trees were cut down than necessary, suit was brought, and the men were sentenced to pay a fine of $50 each, and in default to be committed for fifty days. Judge Endlich handed down an opinion, limiting the rights of such companies.

COMMERCIAL CABLE COMPANY.—The plan by which the Postal Company is brought into closer union with the Commercial has been carried through. It is provided that the plan will go into operation on January 1, 1897. The plan calls for the issue of $20,000,000 of bonds, $15,000,000, of which is to be paid for the plant, etc., of the Postal Telegraph-Cable Company and the $5,000,000 to be used hereafter for the extension of telegraph lines, etc. The bonds are 4 per cent., payable in gold, and a new departure has been made in the payment of interest quarterly.

Synopsis of Current Electrical Literature.

EDITED BY MAX OSTERBERG, E. E.

Central Stations:

SOUTHERN ELECTRIC LIGHT AND POWER CO., PHILADELPHIA, PA.—This station furnishes a considerable and important part of the city with arc lighting. The article explains the essential features.—"Elec. Eng'r.," Nov. 25, '96.

Dynamos and Motors:

BOOSTING WITH ALTERNATING CURRENTS.—By Alexander Russell, M. A. After briefly stating the way in which boosting circuits was first suggested, author takes up the following problems and deduces a mathematical, practical formula for each: 1. Boosting an open circuit. 2. Finding the ratio of the inductances of two coils by using a voltmeter only. 3. Finding resistances of the coils from the readings of the ammeter and voltmeter with alternating currents. 4. Finding the three inductances. 5. Formulæ for boosters. These show that as we increase the load, the ratio of the currents in the main and boosted circuits tends to a constant value.—Lond. "Elec.," Nov. 13, '96.

Electro-Chemistry:

TEMPERATURE CO-EFFICIENT OF THE HIBBERT ONE-VOLT STANDARD CELL.—In this cell the rise in value is very much less than 1-10,000 of a volt per degree, or taking the rise from 16 to 31 degs. C. (1.0004) of .0011 of a volt in 15 degs., it amounts to .0000733 of a volt per degree, or less than .01 per cent per degree.—Lond. "Elec.," Dec. 4, '96.

APPLIED ELECTRO-CHEMISTRY.—By James Swinburne. Lecture delivered before Society of Arts. After pointing out the dangers of blindly following formulæ for calculating e. m. f., developable in cells, author gives some calculations from the point of view of thermo dynamics; he then attacks the generally adopted theory of seat of e. m. f. in a cell, admitting, however, that in many cases his adverse views are due to differences in definition.—"Elec.," Nov. 4, '96.

TURBO ELECTRIC GENERATORS FOR ALKALI WORKS. Illustrations of a large machine used for the decomposition of salt into chlorine and caustic soda.—"Scient. Am. Suppl.," Nov. 21, '96.

Electric Railways:

HOW TO INCREASE THE WORKING EFFIENCY OF RAILWAY MOTORS.—By Wm. Baxter, Jr. It is shown in the article that to reduce the field cross-section so as to obtain higher velocity with larger effort is not a wise course to pursue, since increase is only obtained by an expenditure of an unreasonable amount of energy. For high speed motors a low magnetizing force should be used. The article is concluded with a table of current, horizontal effort, speed, power and efficiency.—"Elec. World," Nov. 7, '96.

Electrical Mining:

SIEMENS-HALSKE PROCESS IN OPERATION AT CHAPACA, WASH.—The Wyandotte Mining, Milling and Smelting Company are the first ones in this country to adopt the puric-potassic cyanide solution for the electrical precipitation of gold. In this process the use of zinc is entirely abandoned reducing the cost to a considerable degree.—"Elec. Journal," Dec. 1, '96.

Electro Therapeutics:

ELECTRICAL TREATMENT OF LOCOMOTOR ATAXIA. —By William Harvey King. Discussion of the treatment of one of the chronic diseases of the spine.—"Journ. of Electro-Therap.," Oct., '96.

THE TREATMENT OF RHEUMATISM BY ELECTRICITY.—By Chester G. Higbee, M. D. The galvanic current and electric massage are both frequently used with good results.—"Journ. of Electro-Therap.," Oct., '96.

THE THERAPEUTIC EFFECTS OF HIGH FREQUENCY CURRENTS.—By M. D'Arsonval. An apparatus, very similar to the Tesla oscillator was used and applied to patients suffering from diabetes with very favorable results; details of cases are described in L'Electricien and translated in Lond. "Elec. Rev.," Nov. 20, '96.

Lighting:

ON THE RESISTANCE OF THE ELECTRIC ARC.—By Julius Frith and Charles Rodgers, B. Sc. A carefully prepared dissertation with an investigation of the alternating current arc.—Lond. "Elec.," Nov. 13, '96.

Measurements:

MEASUREMENT OF TEMPERATURE; AN APPLICATION OF THE MEASUREMENT OF RESISTANCE.—By G. M. Clark, B. A. An outline of the elements of the subject of thermometry forms the first part of the paper; then the methods and principles applied for the measurement of resistance in order to determine measure of temperatures is made use of. The article consists of several sections, the first part (thermometry), being contained in Lond. "Elec.," Dec. 4, '96.

CALIBRATION OF A BRIDGE WIRE.—By W. M. Stine. An auxiliary wire method, which may easily be used by students.—"Elec. World," Nov. 7, '96.

AN INEXPENSIVE, ADJUSTABLE CONDENSER FOR HIGH POTENTIALS.—By Lucien I. Blake. A two-quart glass bottle filled partially with slightly acidulated water and containing an ordinary electric light carbon, which is connected to one terminal of the high potential circuit, is immersed in a tin jar 7 inches high, 8 inches diameter at top and 5 inches at bottom. This jar is placed on a metallic plate which forms the other terminal.—"Elec. World," Nov. 7, '96.

Miscellaneous:

THE ELECTRIC YACHT UTOPIAN.—Description of Mr. Astor's yacht. There are 408 storage cells, each having a rated capacity of 300 ampere hours. Two motors are used which may be run in series, multiple or separate. For various details, see "Elec. World," Nov. 7, '96.

UTILIZATION OF WASTE GASES FROM BLAST FURNACES.—In Hoerde, Germany, an interesting plant is installed in the large iron works. Gas from the blast furnaces, a kind of Dowson gas, is to be utilized in large gas engines coupled directly to a three-phase dynamo. Note in Lond. "Elec.," Nov. 13, '96, from Elektrotechn. Anz.

Power Transmission:

SMITH'S ELECTRO-MAGNETIC ELEVATOR.—The principle of the invention is the use of the solenoid. When the elevator is raised, the solenoid is drawn in, and the reverse action takes place when the car is lowered.—"West. Elec.," Dec. 19, '96.

Roentgen Rays:

NON-DEFLECTIBILITY OF CATHODE RAYS.—By Battelli and Gabrasso. In an article in Nuovo Cimento the authors claim to have discovered certain kinds of cathode ray which are not deflectible by a magnet. Note and editorial notice in Lond. "Elec.," Dec. 4, '96.

RECENT ROENTGEN RAY OBSERVATIONS.—By T. A. Edison. A list of chemical crystals fluorescing to the Röntgen ray in addition to those published in the "Elec. Eng'r.," March 25 and April 1, '96.—"Elec. Eng'r.," Nov. 18, 96.

X-RAYS.—By John Macintyre, M. B., C. M. C. F. S. Author, who is a throat and nose specialist, discusses the different conditions of the tubes, then refers favorably to the use of the camera and in his observations on the fluorescent screen he remarks that a coarse, thick screen has given him favorable results.—Lond. "Lancet," Nov. 7, '96.

THE EFFECT OF THE RAYS ON URINARY AND BILIARY CALCULI.—By Henry Morris, M. F. R. C. S. An illustrated article showing different kinds of calculi as they appear on the photographic plate after having been removed from the body.—Lond. "Lancet," Nov. 14, '96.

SOME EXPERIMENTS WITH ROENTGEN'S RADIATION.—By Prof. Threlfall and Mr. Pollock. Authors give results made with a simple tube which they claim can be made by any one familiar with elementary glass blowing.—Lond. "Elec. Rev.," Nov. 20, '96.

THE ESTIMATION OF THE SIZE AND SHAPE OF THE HEART BY THE ROENTGEN RAYS.—By H. Campbell Thomson, M. D. According to the author it is apparent that the outline of the heart and to some extent its movements can be seen by the aid of the Röntgen rays. He describes his method in "Lond. Lancet." Reprinted in "Elec. Rev.," Oct. 28, '96.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED DECEMBER 22, 1896.

Alarms and Signals:—

SPEED INDICATING ALARM. B. F. Card, Brooklyn, N. Y., 573,568. Filed Nov. 1, 1895.
Comprises a centrifugal device governed by the trolley, a bell with its knocker-support, and means for securing the adjustment of the support, so that the bell will ring at a predetermined speed of the car.

ELECTRIC SIGNALING APPARATUS. F. B. Herzog and S. S. Wheeler, New York, 573,591. Filed March 12, 1895.
The signal may be set to operate at a predetermined time.

ELECTRIC SIGNALING APPARATUS. F. B. Herzog and S. S. Wheeler, New York, 573,592. Filed Jan. 29, 1886.
Comprises a transmitter organized to transmit two separate variable signals at one transmission and at a receiving station an apparatus comprising two progressively moving elements, each controlled by a magnet, the first magnet being controlled by the first part of the transmission, and the second magnet by the second part.

ELECTRIC SIGNAL OPERATING DEVICE FOR RAILWAY TRAINS. G. F. and F. K. Singer, Mingo Junction, Ohio, 573,716. Filed May 22, 1896.
Means to announce to the engineer and conductor of a train when same has broken apart.

ELECTRIC FLOOR PUSH. H. C. Thompson, Boston, Mass, 573,723. Filed March 2, 1896.
Details of construction.

Batteries, Primary:—

ELECTRIC BATTERY. A. E. Stephenson, Chicago, Ill., 573,493. Filed June 29, 1896.
Adapted to supply current for bicycle lamps.

Distribution:—

SYSTEM FOR GENERATING AND DISTRIBUTING ELECTRICAL ENERGY. C. M. Green, Cleveland, Ohio, 573,647. Filed May 23, 1896.
Comprises a dynamo provided with two or more separate sets of armature coils, separate working circuits connected between and included in series, with the separate groups of armature coils, and automatic cut-outs for short circuiting any one of the working circuits should it become broken.

Dynamos and Motors:—

ELECTRIC ENGINE. I. T. Dyer, Chicago, Ill., 573,581. Filed March 30, 1896.
Adapted for supplemental use on a steam locomotive.

Electro-Metallurgy:—

PROCESS OF AND MACHINE FOR MAGNETIC SEPARATION. R. H. Sanders and C. T. Thompson, Philadelphia, Pa., 573,485. Filed Aug. 10, 1892.
Details of construction.

ELECTRIC METAL SEPARATOR. H. H. Whitacre and A. C. Wolff, Wellsville, Ohio, 573,741. Filed Nov. 8, 1895.
A magnet having the faces of its opposite-placed poles recessed to form a conduit, and a mass of diamagnetic metal embraced between the opposite faces of the poles and extending longitudinally of the conduit and adapted to divide the current and deflect the material toward the poles.

Heating:—

ELECTRIC HEATER H. L. Taylor, Corning, N. Y., 573,629. Filed Aug. 6, 1896.
Comprises an electric conductor, an insulating enclosure within which the conductor is contained, a body of practically non-conducting liquid within the enclosure, and an outer heat-radiating body.

REGULATOR FOR ELECTRIC HEATERS. A. D. Lagrelle, Louvres, France, 573,670. Filed Jan. 29, 1894.
Means for heating water-closet seats and regulating the amount of current supplied.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. E. P. Hopkins, New York, 573,464. Filed June 13, 1894.
Focusing lamp adapted for lantern projection.

ELECTRIC ARC LAMP. E. H. A. H. R. Von Nollendorf, Vienna, Austria-Hungary, 573,526. Filed April 9, 1896.
Dispenses with the tubular upper part containing feed mechanism common to arc lamps.

ELECTRIC ARC LAMP. P. F. H. Queisser, Charlottenburg, Germany, 573,617. Filed Jan. 24, 1896.
Feed mechanism for alternating arc lamps.

ELECTRIC LIGHT SUPPORT. E. J. Fulghum, Traverse City, Mich., 573,817. Filed June 24, 1895.
Details of incandescent lamp support.

ELECTRIC ARC LAMP. J. A. Mosher, Chicago, Ill., 573,830. Filed Oct. 22, 1896.
Feed mechanism for lamps of the "gravity-feed" type.

Miscellaneous:

ELEVATOR. C. R. Pratt, New York, 573,531. Filed June 29, 1891.
Comprises current regulator and circuit reverser on the elevator car, a hand wheel and a cable connecting it with and to positively operate the current regulator and circuit reverser.

COMBINED TOILET PAPER HOLDER AND ADVERTISING DEVICE. W. Fisher, Chicago, Ill., 573,586. Filed Oct. 28, 1895.
Details of construction.

COMBINED LIGHTNING AND WATER CONDUCTOR. L. Adams, Buffalo, N. Y., 573,750. Filed Sept. 30, 1896.
Details of construction.

ELEVATOR MECHANISM. J. H. Clark, Boston, Mass., 573,809. Filed July 28, 1890.
Details of construction.

ELECTRIC ELEVATOR. P. W. Leffler, Chicago, Ill., 573,820. Filed Aug. 19, 1895.
The combination with the car provided with an armature, of combined magnetic-field producing devices and guide extending along the line of travel, for co-operation with the armature and a car, to propel and guide it.

Railways and Appliances:—

APPARATUS FOR PREVENTING COLLISIONS ON ELECTRIC RAILWAYS. B. C. Tilghman, Jr., Philadelphia, Pa., 573,496. Filed April 13, 1894.
The combination with crossing tracks of means under the control of a train moving along one track for temporarily cutting the electricity off from a portion of conductor along the track.

TROLLEY POLE GOVERNOR. V. T. Lynch, Chicago, Ill., 573,517. Filed March 4, 1896.
Means to keep the trolley rope taut while permitting the rise and fall of the pole as the car travels.

TROLLEY ADJUSTING AND REGULATING DEVICE. C. F. Randall, Denver, Colo., 573,535 Filed March 31, 1896.
Details of construction.

AUTOMATIC SYSTEM OF DISTRIBUTION AND CONTROL FOR ELECTRIC RAILWAYS, ETC. W. H. Cooley, Brockport, N. Y., 573,645. Filed Aug. 3, 1895.
Consists in supplying the current to the car over a series of working conductors, in such a way that a working conductor to the rear as well as another one in advance of the motor-car is automatically cut out.

ELECTRIC RAILWAY P. W. Leffler, Chicago, Ill., 573,819. Filed Aug. 12, 1895.
Comprises field magnets extending along the line of travel, a series of co-operating magnetic sections arranged longitudinally of the car, and a controller on the car for rendering the magnetic sections operative or inoperative, cumulatively, in pairs, one on each side of the center of the armature.

ELECTRIC RAILWAY, ETC. P. W. Leffler, Chicago, Ill., 573,821. Filed Sept. 26, 1895.
The combination with a car of field magnets extending along the line of travel, and a rotary magnetic body, carried by the car-body, having spirally arranged pole pieces subject to the action of the field.

ELECTRIC RAILWAY, ETC. P. W. Leffler, Chicago, Ill., 573,822. Filed March 11, 1896.
Means for controlling the field sections.

MOTOR CAR TRUCK. P. W. Leffler, Chicago, Ill., 573,823. Filed March 21, 1896.
In combination with a sectional truck, a sectional armature, carried, one section on each of the truck sections, and a common universal joint applied to couple together the truck sections and the armature sections.

Regulation:—

AUTOMATIC SPEED REGULATOR FOR ELECTROMOTORS. L. Denayrouze, Paris, France, 573,767. Filed Nov. 26, 1895.
Comprises a contact disk mounted on the motor-shaft and connected with one brush of the commutator, a disk mounted on, and insulated from, the motor-shaft and provided with a contact, electric connection of the disk with the generator, and a contact having a flexible connection with the shaft and adapted to engage the former contact.

Switches, Cut-Outs, Etc:—

ELECTRICAL RESISTANCE DEVICE. D. C. Voss, Malden, Mass., 573,558. Filed March 16, 1896.
Composed of carbonized fibrous material, a metallic oxid, and a binder.

ELECTRIC SWITCH. W. and H. Boardman, Lancaster, Pa., 573,807. Filed March 28, 1896.
Push button switch.

Telegraphs:—

ELECTRICAL SWITCHING APPARATUS. F. W. Jones, New York, 573,601. Filed Oct. 15, 1896.
Employs a spring jack, two or more flexible cords, a plug for each cord, a take-up device for each cord and means for locking or holding a cord against the action of the take-up device.

Telephones:—

TELEPHONE EXCHANGE SYSTEM. W. W. Dean, St. Louis, Mo., 573,575. Filed June 11, 1896.
The combination with metallic circuit and grounded telephone-lines, of a common battery, and an additional battery in circuit with the grounded lines and adapted to supply additional electromotive force to the grounded lines, whereby the standard current may be maintained upon both metallic circuit and grounded lines.

COMMON BATTERY TELEPHONE SYSTEM. W. W. Dean, St. Louis, Mo., 573,576. Filed Sept. 19, 1896.
A local transmitter circuit comprising an induction coil and a microphone included in circuit with the induction coil, and a battery adapted to direct current through the primary and secondary helices of the induction coil in series, the primary and secondary helices being also connected in series in the path of the voice-currents.

ELECTRICAL CONNECTING CORD. C. H. McEvoy, Lowell, Mass., 573,612. Filed Feb. 24, 1896.
Comprises a conducting core, a conducting tip in electrical connection with the core, a non-conducting supporting-cord and a link, arranged to surround the tip and to receive the supporting cord.

TELEPHONE ATTACHMENT. W. O. Christopher, Hillsborough, Texas, 573,441. Filed Aug. 29, 1895.
A device which will support the weight of the telephone receiver on the switch lever whether the receiver be hung on the hooks of the lever or dropped.

FUNNY NEWS FOR AMERICAN INCANDESCENT LAMP MAKERS.

A dispatch from Washington says: "As a matter of curiosity United States Consul Morris at Ghent reports to the State Department that the most expensive product in the world is the charcoal thread employed for incandescent lamps. It is for the most part manufactured at Paris and comes from the hands of an artist who desires his name to remain unknown in order to better protect the secret of manufacture. It is by the gramme that this product is sold at wholesale. In reducing its price to the basis of pounds, it is easily found that the filaments for lamps of twenty candles are worth $8,000 per pound, and that for lamps of thirty candles they are worth $12,000 per pound. The former have a diameter of twenty-

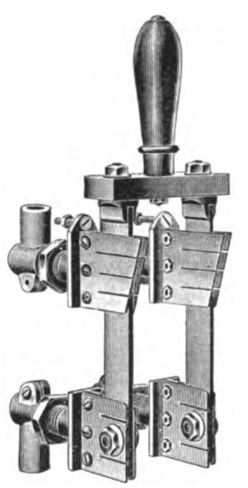
thousandths of one millimeter, and the latter four and one-half thousandths of a millimeter. The filaments for lamps of three candles are so light that it would require nearly 1,500,-000 of them to weigh a pound. As the length of each of them is ten centimeters, their total length would be 187 miles." The name of the "unknown artist" is "Legion." He lives at several places.

Trade Notes and Novelties

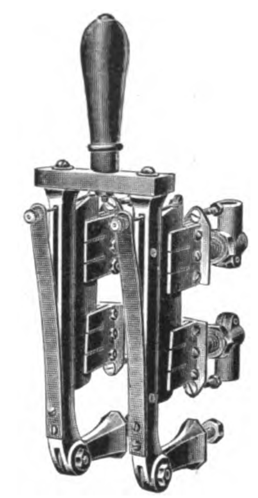
AND MECHANICAL DEPARTMENT.

THE WESTERN ELECTRIC KNIFE SWITCH.

THE demand for high grade knife switches has brought upon the market designs of various makers. The most recent are the type "E" and type "Q" manufactured by the Western Electric Company, Chicago. The contacts of these switches are all rolled tempered copper and the greatest care in construction and design has been observed in order that the switches would carry their rated capacity in amperes



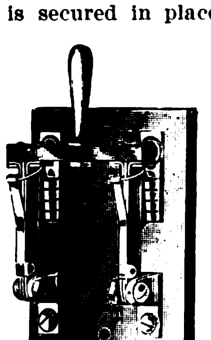
TYPE E FOR SWITCHBOARDS.



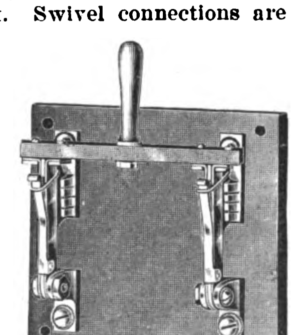
TYPE Q FOR SWITCHBOARDS.

without showing any heating of the parts. In placing and fastening the jaws in position they are not soldered, but bolted to the metal plates or lugs as can be seen from the illustration. By this method the temper of the jaws is in no way injured and they will always grasp the blade of the switch with an equal and unvarying contact which will not deteriorate with time. The hinge contact is made in the same way and the bolt which passes through the hinge is provided with a lock nut, preventing any liability of loosening or poor contact at this point. The blades are of drawn copper, hand finished.

The base is extended for connections on back of board and is secured in place by a lock nut. Swivel connections are



TYPE Q WITH SLATE BASE FOR 110 VOLTS.



TYPE Q WITH SLATE BASE FOR 500 VOLTS.

provided which will admit of the circuit wires being brought into the switch from any direction. The switches are all made to gauge and any repair part can be obtained and a damaged part replaced in a few moments.

The type "E" is for station and switchboard work, being of the regular jaw pattern. The type "Q" is essentially the same as type "E" with the addition of a quick break spring and is especially approved by the underwriters for an entrance or service switch for motor work, constant potential arc, or incandescent lighting.

The cuts of quick break switches mounted on slate bases are shown, one for a pressure up to 110 volts, the other for a pressure up to 500 volts.

An illustrated circular and price list on "E" and "Q" switches has been issued by the Western Electric Company and a number of sizes are carried in stock.

THE PHOENIX CARBON MFG. COMPANY DOUBLING ITS PLANT.

The entire city block just north of the present plant of the Phœnix Carbon Manufacturing Company of St. Louis, Mo., has been purchased by that company and the establishment in the very near future will be greatly enlarged by the addition of more special carbon machinery and the erection of new carbon furnaces and ovens.

This move is of especial interest to the electrical and allied industries, as it is an indication of the growing improvement of one of the most important carbon factories, entirely independent of the association, which is recognized as the carbon trust or combination, known to exist. The Phœnix Carbon Manufacturing Company has been established between two and three years and its organization by Mr. S. G. Booker was done with the strong belief that, owing to the condition of the carbon trade, there was an opportunity in view of the carbon-making alliance for such an independent company. Col. Booker, because of his specific knowledge of carbon, its characteristics, and application for electrical uses, combined with his popularity in the electrical field, was peculiarly fitted for the management.

The company will continue the production of staple forms of carbons, making also in greater quantities the battery carbons for which it has gained reputation, and also carbon specialties for telephone, motor brushes, and the multitudinous forms in which carbon is used.

THE PURITAN 100-HOUR ALTERNATING ENCLOSED ARC LAMP.

Through a perversity of the types the Puritan enclosed arc lamp for alternating circuits mentioned in our last issue was credited with a run of only 10 hours. It goes without saying that 100 hours was intended. Ten-hour lamps don't go for much nowadays, it would appear.

CUTLER-HAMMER MFG. CO.

Mr. E. W. Hammer, late secretary of the Cutler-Hammer Manufacturing Company, Chicago, has sold his interest in the above company to Horace S. Smith and Harry H. Cutler. Mr. Smith is well known to the mechanical world as the late general manager and vice-president of the Illinois Steel Company, and Mr. Cutler needs no introduction to the electrical trade.

The company has been reorganized and put on a sound financial basis, with a largely increased capital. Their factory is being enlarged to take care of the rapidly growing business, and to better enable them to keep up their reputation for prompt shipments and high class work.

GROWTH OF THE STANLEY ELECTRIC CO.

The Stanley Electric Company held a special meeting at Pittsfield, Mass., on Dec. 20, and voted to increase the capital stock of the concern from $300,000 to $500,000. This step has been rendered necessary by the constantly increasing business of the company, and the growing magnitude of the plants it has to instal. It is expected that all of the increased stock will be taken by stockholders and that it will be taken up by February 15. The company expects to double its business by the end of the next year.

LEFFEL WHEELS AT NIAGARA.

The new hydraulic power company at Niagara Falls have now in successful operation their new power plant, consisting of four of the Leffel celebrated Niagara type of turbines, each of about 2,200 horse-power capacity, or giving in all some 9,000 horse-power. These turbines drive eight generators of something over 1,000 horse-power each; two generators being connected directly to the shaft of each wheel, one being placed on each side. The same company have four other of the Leffel Niagara turbines, using in all eight of that style of wheel. The plant was recently illustrated and described in The Electrical Engineer.

MR. G. G. LUTHY, Peoria, Ill., made a short business trip to Chicago recently and was as usual hustling for business in the interest of the Royal Electric Company.

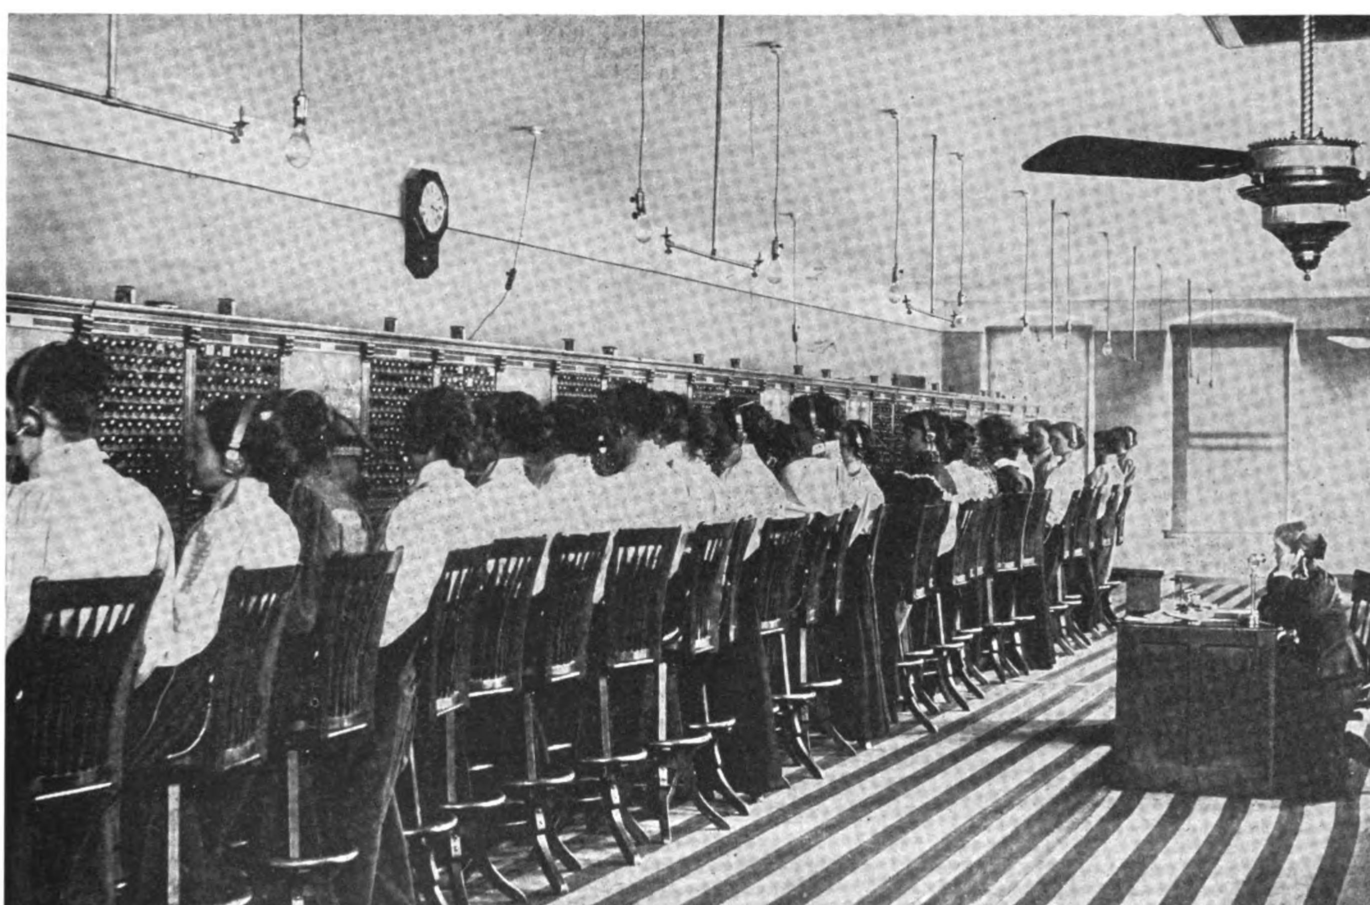
THE "INDEPENDENT" TELEPHONE EXCHANGE AT GRAND RAPIDS, MICH.

ONE of the largest and most progressive of the telephone exchanges started in opposition to the pre-existing Bell interests is that at Grand Rapids, Mich. The exchange is carried on by the Citizens' Telephone Co., who until recently had provided for 1,800 subscribers, but who now have been putting in additional capacity, bringing the switchboard provision up to 3,000. When the exchange was started, each operator was given 100 drops to look after. The exchange is so busy, however, that this has been found too much, and the new board has only 75 drops to each section. The Citizens' company procured an ordinance from the council, built its exchange, and on July 1, this year, began business. The ordinance fixed the rates at $24 and $36 for residences and business places respectively. The company cut this to $20 and $30 in consideration of subscribers signing a three-year contract. The new company started with 1,200 subscribers and has since increased to 1,750. Before the competition came in the old Michigan Bell company had 1,600 subscribers. The list is now about 1,000, it is stated, and of these about 500 use both systems.

When the reduced rates went into effect the old company did not directly cut the rates to meet the competition, but accomplished the same thing by giving rebates. Since July the old company had shown no particular sign of activity, but ever since the construction on the new exchange began it has been busily engaged improving the service and putting in the latest appliances. It is now ready to fight, and on Jan. 1 new subscribers or old subscribers returning to the fold will be given free service for three months. What will happen after that time has not yet developed.

In addition to the new company at Grand Rapids, local companies have been established at Muskegon, Holland, South Haven, Allegan, Lansing, Hastings and at other points, and during the summer and fall these towns have all been connected with Grand Rapids, thus affording a State service, but the lack of an independent exchange in Detroit will make that city inaccessible for practical purposes to the non-Bell subscribers. It is said that the completion of the new Home Company's system in Detroit will change this condition of affairs.

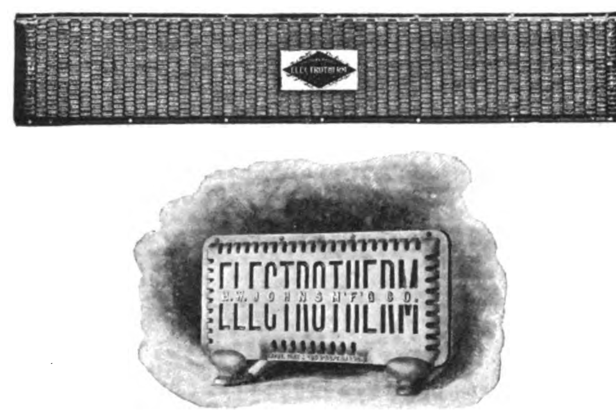
The apparatus for the Grand Rapids Citizens' Telephone Co. has been built by the American Electric Telephone Co., of Kokomo, Ind., the details of whose apparatus have already been illustrated in these pages. The officers of the Citizens' Company are E. B. Fisher, president; C. F. Rood, vice-president; A. S. Musselman, secretary; J. M. Barnett, treasurer; J. B. Ware, manager. Their system is one of the largest and best managed of those which have sprung into existence since the expiration of the Bell patents and the effort to extinguish the Berliner.



AMERICAN ELECTRIC TELEPHONE CO.'S APPARATUS, CENTRAL EXCHANGE, CITIZENS' TELEPHONE CO., GRAND RAPIDS, MICH.

"H. W. J." ELECTRIC CAR HEATERS.

OUR illustrations show two of the forms of the "H. W. J." car heater which are in extensive use on various electric railroads. They are of a panel heater 50 inches long, and of an upright heater for cars having cross seats. The method of constructing these two types of heaters is as follows: The resistance wire, wound and insulated with asbestos, is woven into a cloth, which is saturated with a water-proofing compound and attached to an asbestos backing, similarly prepared, the whole thing being subjected to a baking at a high temperature. The heater thus formed is, in the case of the panel



H. W. JOHNS ELECTRIC CAR HEATERS.

heaters, inclosed in a punched steel casing, the finished heater being but seven-eighths of an inch thick, 9 inches wide and 50 inches long, and weighing sixteen and a half pounds. The upright heater has a cast iron casing and weighs 17 pounds. This heater is 18 inches long, 10½ inches high and 2¼ inches thick.

The use of "H. W. J." heaters introduces radical improvements in the methods of heating street cars. As the panel heaters are very thin, when placed on the faces of the panels below the seats, they do not take up space otherwise available or interfere with the movements of the passengers. No cutting of the woodwork is required for their installation. It has heretofore been customary to place a few electric heaters in a car and to operate them at a high temperature, to the discomfort frequently of the passengers nearest them, and at a risk of scorching clothing and setting fire to the car. In the "H. W. J." system, it is recommended to install as many heaters as the available space will permit, with the view, by so doing, of being able to operate the heater at moderate temperatures individually and to distribute the warmth more uniformly throughout the car. The effect of heating a car by this method compared with a car heated by a smaller number of heaters is immediately apparent. The large radiating surfaces furnished by the H. W. J. heaters also insure a greater economy in the uniform distribution of the heat to the passengers, and a longer life for the heaters, as under normal conditions no part of the heaters is subjected to such an excessive temperature as to lead to deterioration from overheating, while rusting-out and crystallization through vibration are also promoted by the compact, and practically air-tight envelope.

In the weaving of the heater, the resistance wire is separated into two sections, known as the upper and lower. In regulating the temperature, to obtain the least amount of heat, the upper sections of all the heaters are connected in series. For a moderate or medium temperature, the lower sections of all the heaters are connected in series, and to obtain the greatest heating effect, the upper and lower sections are connected in multiple. These combinations are effected by the improved "H. W. J." regulating knife switch, which is simple and durable in construction and designed to endure the rough treatment to which devices on a trolley car are liable.

ADVERTISERS' HINTS.

THE CENTRAL ELECTRIC COMPANY announce they are ready to "wade" in for 1897 business and their friends may be sure they will not wade in vain.

THE CROCKER-WHEELER ELECTRIC COMPANY advertise a complete line of dynamos and motors and all things pertaining thereto.

G. A. FREI & CO., 17 Bromfield street, Boston, Mass., show several styles of Crookes tubes in their "ad" this issue. A new catalogue of everything needed in X-ray work may be procured on application.

THE BERLIN IRON BRIDGE COMPANY illustrate a roof designed and built by them for the Norwalk (Conn.) and South Norwalk Electric Light Company. The dynamos are moved by a traveling crane of 4,000 pounds capacity, supported by the roof trusses.

THE WABASH RAILROAD COMPANY call attention to their excellent train service to the West from New York and Boston. Tickets are sold with ten days' stop-over privilege at the Falls.

THE AMERICAN ELECTRIC HEATING CORPORATION in order to enable dealers to test the value of electric heating goods as money-makers, have made up an assortment of good sellers and send free with each assortment a three-foot oak case in which to display them.

WESTERN NOTES.

ROBINSON & MORSE, Chicago sales agents of the Buckeye Engine Company, are pushing hard for a share of the engine trade in the electric light, street railway, and power field in that territory, and have recently closed the following contracts: Calumet Electric Street Railway Company, Chicago, 1,000 horse-power cross compound; Lincoln Park, Chicago City Lighting Station, two 200 horse-power tandem; Moline, Ill., Electric Light and Power Company, 600 horse-power cross compound; Western Electric Company's plant, Chicago, 200 horse-power cross compound; Western Light and Power Company, Chicago, 600 horse-power cross compound. Mr. A. M. Morse, who until recently looked after the interests of the Buckeye Company in St. Louis, has now joined forces with Mr. Robinson, the Chicago representative of the concern, and both are located at 1249 Marquette Building.

MR. R. L. McOUAT, of Varney & McOuat, Indianapolis, was a recent visitor to Chicago, where he not only attended strictly to business, but also was able to combine a little pleasure at the same time.

THE MISSOURI TELEPHONE MANUFACTURING COMPANY, St. Louis, Mo., have issued a large chromo-lithographic calendar for 1897, which will find many admirers. The picture represents a little girl in dressing robe who has climbed up on a chair in order to have a confidential talk over the telephone with Santa Claus. The idea is carried out with great cleverness and delicacy of treatment.

MR. CARL KAMMEYER, who was formerly connected with The Electrical Engineer, as its Western representative, has now joined the staff of "Farm Machinery" in St. Louis, a city where he is well known as an old resident. Our contemporary is to be congratulated upon a very valuable acquisition.

THE ELECTRIC APPLIANCE COMPANY report a daily increase in their "Armorite" sales, and are more and more pleased by the way the trade seems to appreciate their efforts to give them a superior article in the line of an iron armored conduit. The demand increases.

THE METROPOLITAN ELECTRIC COMPANY, of Chicago, who are Western Agents for "Mac" Tape, report a large demand for this standard article, which they carry in stock. Upon test and comparison, the "Mac" Tape will show, it is asserted, a larger proportion of good india rubber in its composition than any other tape. The adhesive and insulating qualities are very high.

NEW YORK NOTES.

MR. A. O. SCHOONMAKER, 158 William street, New York, has opened a Western branch at 1563 the Monadnock, Chicago, where he carries a full line of electrical mica, Mr. John Childs having charge of the business in that territory.

HUEBEL & MANGER, Brooklyn, N. Y., have reason to congratulate themselves upon the amount of business they are doing; the last two months being the best they have ever had. Their plant is being driven to its utmost capacity, and they are turning out bells and push buttons in such quantities as to make one wonder where they are all going to be used.

THE ASHCROFT MANUFACTURING COMPANY, of 111 Liberty street, New York, have just issued their new catalogue, a copy of which they have favored us with. It is bound in cloth, admirably illustrated and full of information. Among the noteworthy specialties included are the Edson pressure recording and alarm gauge, the Tabor steam engine indicator and the Moscrop speed recorder. It is a useful buying guide for central station and railway managers.

ALBRIGHT & CO., of New York City, are to establish chemical works at Niagara Falls and use the power there.

THOS. J. FAY & ASSOCIATES, 143 Liberty street, New York, New York agents and general exporters for the Crocker-Wheeler Electric Company, have been awarded the contract for the lighting plant for Hull & Co., of Poughkeepsie, N. Y. The dynamo will be one of the latest perfected multipolar Crocker-Wheeler machines of 600 lights capacity.

MR. JOS. F. O'DAY, who has been for some two or three years in charge of the outside construction work for the C & C Company in New York, has joined the forces of Thos. J. Fay & Associates, electrical engineers and contractors, 143 Liberty street, New York.

MR. WALTER J. JONES, formerly superintendent for the Suburban Electric Light Company, of Scranton, Pa., for the past four years, has been appointed electrical superintendent of the Hackensack (N. J.) Gas and Electric Company.

NEW ENGLAND NOTES.

THE AMERICAN ELECTRICAL WORKS are well known to "have a pudding," and this year they have sent their friends a very pretty little fac-simile of it accompanied by good wishes. They have also sent out a tasteful calendar with a colored representation of their Philadelphia mills.

THE MOSSBERG & GRANVILLE MANUFACTURING COMPANY, Providence, R. I., a notice of whose incorporation and removal to new and larger quarters appeared in our last week's issue, are manufacturing a line of presses which are particularly adapted to the rapid production of sheet metal stampings and of drop forgings for electrical use. Commutator bars and segments, brush holders, incandescent lamp sockets, plain and ornamental stampings for electrical work can be rapidly and economically produced by their means. Among their specialties is a press which will punch armature sheets at one operation, a great saving over the old-fashioned ratchet dial feeding in common use. This firm may well be called a headquarters for presses.

Department News Items will be found in advertising pages.

5721. Sheet 1.	WIRING SECTION PLATE FOR RANGE UP TO 3 VOLTS DROP, 20 AMP., 150 FEET.	A.

The wiring section plate, shown on 5721, Sheet 2, will solve any problem of wiring within the range of 3 volts drop, 20 amperes and 150 feet distance. The distance given being one-half of the electrical distance, and the formulæ is d^2 (circular mils), equals current (*C*), multiplied by distance to point of consumption (*D*), multiplied by the constant 21.21, and divided by volts drop (*V*), or

$$d^2 = \frac{C \times D \times 21.21}{V}.$$

The method of using this wiring section is as follows: Given any three quantities in a wiring problem, to find the fourth. For instance: 8 amperes, 2 volts drop, 124 feet, to find proper size of wire. Find the intersection of 8-ampere vertical line from "ampere" line with 2-volt drop horizontal line from "volts drop" line, and then follow the diagonal line until the horizontal line from 124 feet is reached, which will be on the vertical line from No. 10 wire on the top scale of wire in the B. & S. gauge or circular mils, which is the quantity sought.

The line of sizes of wire under the "ampere" line is the capacities allowed by the underwriters for B. & S. wires when used in concealed work. The use of this is to provide against overloading the wires, which can occur with large drops at short distances. For instance, suppose it were given to carry 12 amperes with 1.25 volts drop, 18 feet; it will be noticed that we have passed in following the diagonal backward to a wire smaller than No. 14 for 12 amperes, which is too small to meet the underwriters' requirements of 12 amperes for No. 14 wire in concealed work, and, consequently, No. 14 wire is the smallest wire that can be used.

If any three quantities are known the others can be found. For instance, we have a No. 9 B. & S. wire and want to reach a consumption circuit of 10 amperes, 110 feet away, and the drop on this load is required. Find the intersection of the two adjacent quantities (that are on opposite sides of the diagonals), such as No. 9 wire with 110 feet, and follow between the diagonal lines down until the line from 10 amperes is reached, when it will be found that 1.8 volts also intersects at this point, and is the quantity sought.

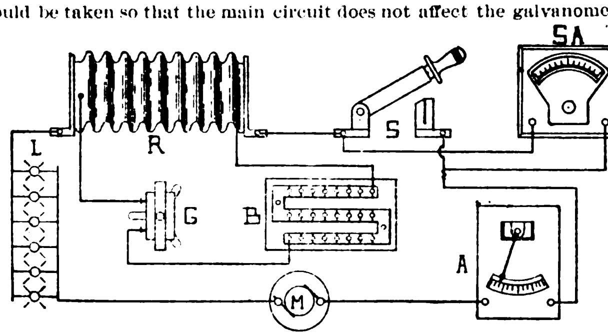
517. Sheet 4.	LABORATORY METHOD OF CALIBRATING AMPEREMETERS.	B.

The diagram shows the method used when the standard amperemeter does not read high enough for full range of amperemeter to be calibrated. SA is the standard amperemeter; R is German silver shunt, unknown resistance, with ample carrying capacity to carry maximum current required, without heating; G is a tangent galvanometer, preferably Thomson or d'Arsonval; B, variable resistance box; M, source of current; L, variable resistance or lamp bank; S, switch to short-circuit standard amperemeter; A, amperemeter to be calibrated. Suppose SA reads to 25 amperes. A is to be calibrated to 200 amperes. Before passing the current through the circuits the galvanometer should be adjusted so that the spot of light reflected from galvanometer mirror is at zero on the galvanometer scale. Care should be taken so that the main circuit does not affect the galvanometer;

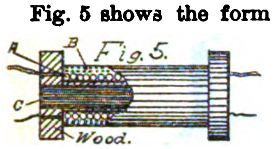


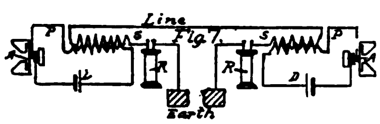
then allow 25 amperes to pass with switch that shunts SA open. The resistance can then be varied in the rheostat, B, until the deflection on the scale is some convenient multiple of the reading of SA. Say, take 5 divisions per ampere; then with 25 amperes, the resistance of B should be adjusted so that there will be 125 deflections on the galvanometer scale, and if the total division of scale is 1,000, we can close switch S and vary the current for the proper readings required on the amperemeter A, within the range of 0 to 200 amperes. There are corrections that will have to be applied to bring the work closer than this, such as allowing for change of resistance due to heating of the shunt, correction of galvanometer deflections which are not strictly tangential, and any error that may be in the standard can be corrected for in the deflections of the galvanometer when it is first set up.

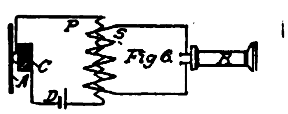
5932. Sheet 3. TELEPHONE CONNECTIONS. B.

The best conditions under which the transmitter can operate, as shown in Sheet 2, is when the current is large, and the resistance of the transmitter circuit low. This is not permissiable with a long distance circuit, or when speaking with receivers in the same circuit, as the transmitter will not, in this case, work under maximum conditions. All telephone circuits are greatly improved in their operation, if the battery current passes through the transmitter and also through an induction coil.

Fig. 5 shows the form of induction coil generally used in telephone work.







The primary (shown at A, Fig. 5) with a few turns is connected, as in Fig. 6, in series with the battery D and transmitter C. It consists of about 180 turns No. 23 B. W. G. copper wire, and measuring .5 of an ohms. This is wound on a hollow spool, and over these turns and insulated from them, is wound the fine wire secondary B. There are 4,000 turns No. 28 B. W. G. on this secondary coil measuring 250 ohms. A core of fine iron wires C is passed through the hollow centre.

Fig. 7 shows a complete set of receivers and transmitters with induction coils, connected up without signalling arrangements. A, transmitter; D, battery; R, receiver; P, primary coil; and S, secondary coil.

5831 Sheet 1. METHODS FOR DETERMINING DATA FOR DYNAMO REGULATORS. B.

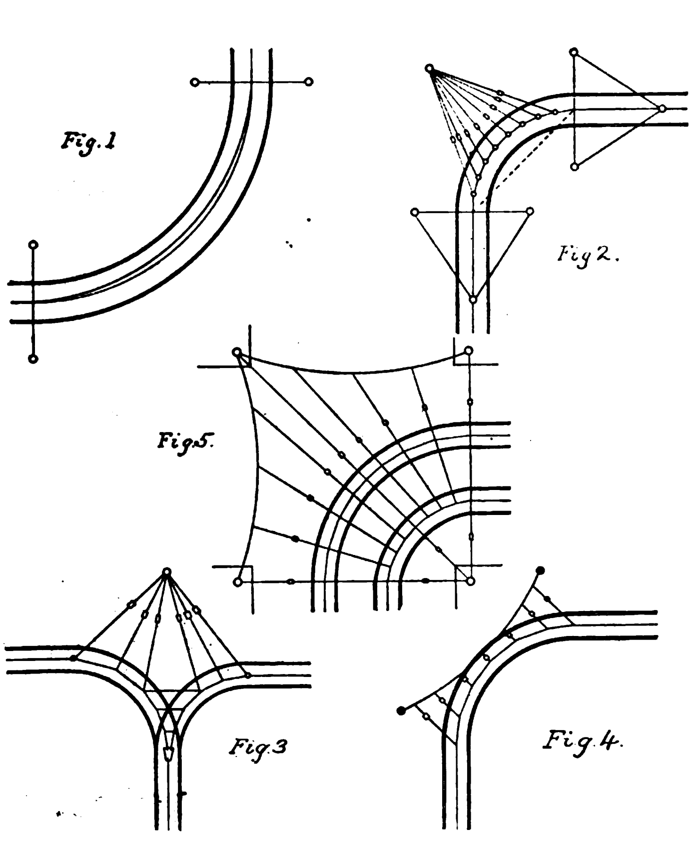
There exists no relation between the fixed resistance of the field of the different types of dynamos and the resistance required in the regulator. In order to control the machine under all circumstances, the regulator, to be properly designed, should have sufficient variable resistance to bring the voltage down on the machine when on open circuit, when the fields are excited from a voltage equal to the maximum voltage of the machine, which is the condition that arises when the machine is bus excited. Data obtained from a self-excited machine is useless for the determination of the proper regulating resistance, and yet this error is very often made. The condition where maximum resistance is required is for compound dynamos, where they are subject to overload or short-circuits, and in this case the shunt field has to be cut down to nearly zero, in order to control the load when it is necessary to burn out a short-circuit with a compound dynamo, which case arises in railway work.

In order to determine the resistance to properly regulate a dynamo, connect in series with the field a variable resistance, and an amperemeter, and then connect the ends of the field to an external source of electromotive force, equal to the maximum given by the dynamo, and when the machine is running at normal speed, insert resistance until the voltage drops at the brushes with armature or open circuit to 10 per cent. below the rated voltage of the machine; then take drop across the inserted resistance with voltmeter and from amperemeter reading figure resistance; then overload the machine, as allowed by the manufacturer, if compound, and see if the resistance is sufficient to control the machine under these conditions, which it should be, if properly compounded.

The number of steps into which this regulating resistance is divided for lighting and power generators, is from forty to eighty; the latter division, if the resistance is properly divided throughout the box is abundant for the best regulation, which is to have the same volts drop on each step, and, with the tapering current, will give low resistance steps at beginning of box, and resistance increasing per step as the current through field decreases.

The method of figuring the resistance wire, in order to secure maximum economy in space and material, will be found in Sheet 2 (to follow).

5733. Sheet 2. ERECTION OF TROLLEY WIRES AROUND CURVES. B.



5733. Sheet 1. ERECTION OF TROLLEY WIRES AROUND CURVES. B.

In a properly erected trolley wire, and with a standard trolley wheel, the pole should never leave the trolley wire in going around curves, and this result can be obtained if the trolley wire is erected with the following precautions:

First—All line tensions should be taken off the trolley wire at the end of both tangents to the curve. This can be done by running strain wires to take up this tension. The location of the curve of the trolley wires should not be directly over the center of the track, except at the points of tangency, but should depart from this curve toward the center, the departure being greater as the radius of the curve decreases. For a 50-foot curve, the trolley wire should be 8 inches inside of the center line of the track, at center of 90-deg. curve. (See Fig. 1, Sheet 2.)

Table 1 shows what this should be for the 90-deg. curves of different radius.

TABLE 1.

Radius in feet.	Distance between centre of track and centre of trolley.	Distance between pull-offs on curves.	Radius in feet.	Distance between centre of track and centre of trolley.	Distance between pull-offs on curves.
35	14"	6"	100	4"	12"
40	12"	7"	120	4"	14"
45	10"	8"	140	4"	14"
50	8"	9"	160	3"	14"
55	7"	10"	180	3"	14"
60	7"	11"	200	3"	14"
70	6"	12"	250	3"	16"
80	6"	12"	300	2"	16"
90	5"	12"	350	2"	16"

In regard to spacing the pull-offs around the curves, Table 1 shows the distance apart that they should be placed in order that the sides of the polygon formed by the trolley wire and pull-offs, will not be of such an angle as to throw the trolley when passing around these curves. In any case, the deflection of the trolley wire at any one pull-off ear should not be more than 10 deg.

With curves laid out with a spiral between the curve and the tangent, it is not necessary to make any difference in guying the trolley wire.

Sheet 2 shows a number of methods of locating pull-offs in order to hold the trolley wire to the proper curve. The original method consists in attaching the pull-off guy directly from the trolley to the pole. These pull-offs, as usual, are provided with turn-buckles, so that the pull-offs can be varied in length, adjusting the trolley to the proper curve. The other general method is the flexible method, where the trolley wire is connected to a heavy span wire by means of pull-offs, and this method has the advantage of equalizing the strains on the different pull-offs, and tending naturally to hold the trolley wire to a curve.

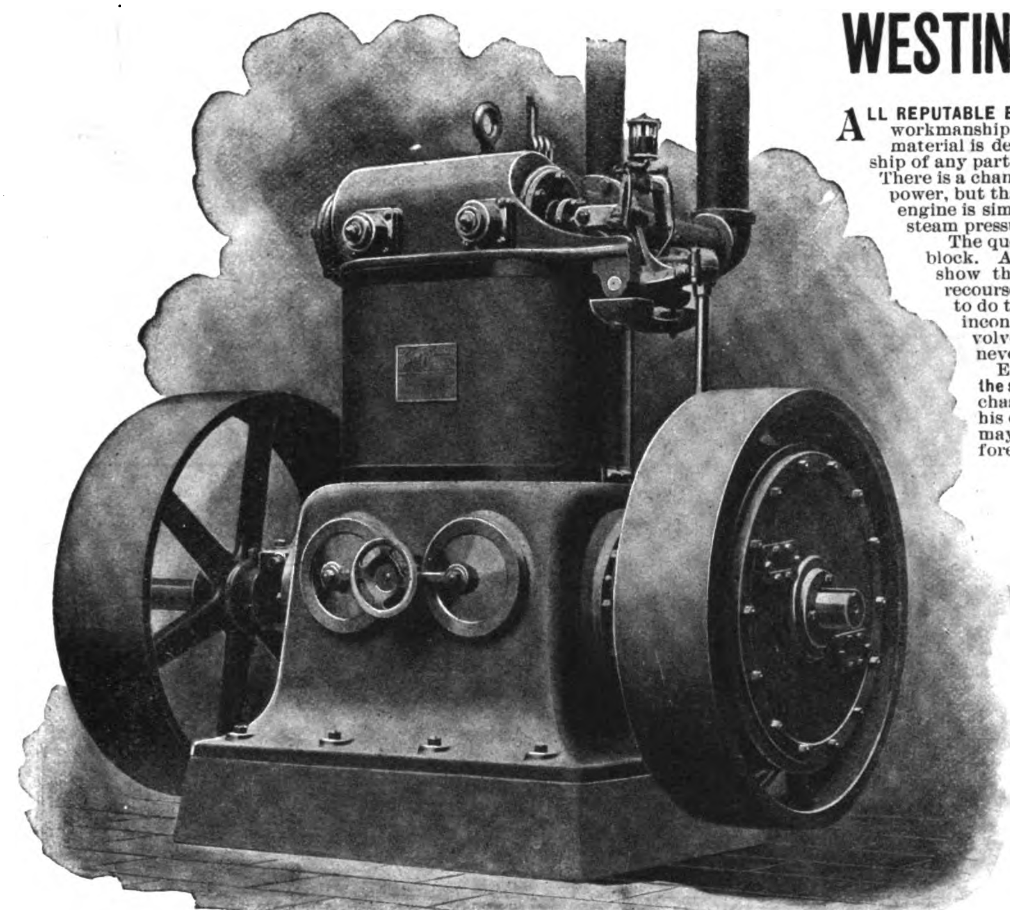
CENTRAL ELECTRIC COMPANY.



WESTINGHOUSE ENGINES.

ALL REPUTABLE ENGINE BUILDERS will guarantee the material workmanship, capacity and economy of their engines. If material is defective, it will be replaced; if the workmanship of any part is not up to standard, it will be made good. There is a chance that the engine may not develop its rated power, but that is not so probable, since the capacity of an engine is simply a measure of cylinders, piston speed and steam pressure.

The question of economy, however, is the stumbling-block. After an engine has been installed and fails to show the **guaranteed economy** the purchaser has no recourse except to take the engine out. If he decides to do this, it means interrupted business and serious inconvenience, aside from the direct expense involved. The consequence is, that it is seldom or never done.

Every engne we build has a record **before leaving the shop**, based on a rigid economy test. Any purchaser so desiring may have his engine tested by his own expert at our shops before shipment, and may accept or reject the engine on that test, before incurring the expense of installation.

FINANCIAL.

ALBANY, N. Y.—The capital stock of the Albany, Helderberg & Schoharie Electric Railway Co. has been increased from $300,000 to $500,000.

STREATOR, ILL.—C. C. Barr has been appointed receiver of the Streator Railway Co. under foreclosure of the $160,000 mortgage. The capital stock of the road is $250,000, and it has been in operation five years.

YOUNGSTOWN, O.—The Youngstown Street Railway Co., and the Mahoning Valley Electric Railroad Co. have been consolidated; the new company to be known as the Mahoning Valley Railroad Co. A. A. Anderson, of Youngstown, is general manager. The Mahoning Valley Railway Co. has filed with the Secretary of State an application to increase the capital stock from $150,000 to $1,500,000 and change the headquarters to Youngstown.

SALISBURY, N. C. will vote on a proposition to issue $100,00 worth of bonds to purchase the city water works and put in an electric light plant.

BALLARD, WASH.—This city has decided to purchase an electric lighting plant, and bonds or warrants will be issued for that purpose. Of the $51,000 authorized for water and electric lights, only $45,000 have been sold, and it is proposed to use the balance for the lighting plant. Bids will shortly be advertised for.

CUMBERLAND, MD.—The Cumberland City Council is considering an ordinance to submit to the voters for an issue of bonds to the amount of $20,000 for an electric light plant.

ELECTRIC RAILWAYS.

PITTSBURG, PA.—Over half a million dollars, it is said, will be expended by the North Side Traction Co. next spring in improving its road, to include a power plant to cost $150,000 to $200,000.

NEWARK, O.—The Ohio Telephone Exchange Association will soon form a company to connect Ohio's sixty independent exchanges, also the forty-five in Indiana, and several in adjoining States. A meeting will be held in Columbus next month for that purpose.

GREENWICH, N. Y.—The application of the Greenwich & Schuylerville Electric Railroad Co. for permission to construct its road has been granted by the State Railroad Commissioners.

MT. VERNON, O.—A. S. Shoemaker, of Ashley, is engaged in establishing an electric railway from Mt. Vernon, Knox County, to Richwood, Marion County, passing through Sparta, Marengo, Ashley and Prospect.

WINNIPEG, MAN.—An application has been made for charter for the Fort Frances & Pacific road, through the Rainy Lake gold country, from Wabigoon station on the C. P. R., electricity to be the motive power, derived from the numerous waterfalls on the route. Subsides are asked from both Provincial and Dominion Governments.

ST. LOUIS, MO.—The People's and the Arsenal Street Railway Companies have decided to consolidate and build several extensions in the suburbs. Charles Green is president of the People's Company.

NEVADA, MO.—H. C. Moore, of this place, has perfected arrangements with St. Louis capitalists for the construction of an electric railway in Nevada, Mo.

MILFORD, CONN.—At the opening of the general assembly in January, an elaborate trolley scheme will be promulgated. A petition has been prepared and signed by J. D. Brown, of Milford, and others, asking for power from the legislature to organize and operate the Milford Traction Company. A franchise for a line of electric road extending from Milford to Stratford, through Wodmont to the city of Derby and through Orange to New Haven over the old turnpike, is asked for.

TELEPHONE.

CHESTER, ILL.—The Harrisonville Telephone Company will begin work next week on the extension of its line from Evansville to this city. It is proposed to connect all towns in this section of Southern Illinois by a telephone system.

CHILLICOTHE, O.—Mr. Isaac McCormick, of Raysville, has completed arrangements with the Home Telephone Company, for the carrying out a new telephone system. The idea which Mr. McCormick advocates is the connecting of Wellston, Coalton, Jackson, McArthur, Hamden, Byers and Raysville with Chillicothe. The new line will tap the Chillicothe line at Vigo.

TOLEDO, O.—The Central Union Telephone Company has removed to its new exchange in the Spitzer Building.

BIGBYVILLE, TENN.—J. D. Hinds, of the Citizens' Telephone Company at Columbia, has surveyed and staked off the line to connect Bigbyville with Columbia. Work will begin upon the construction of the line immediately. It is probable that McCain's and Broadview will connect with this place soon.

GAINESVILLE, TEX.—The National Telephone Company has been absorbed by the local Bell Telephone Company.

NACOGDOCHES, TEX.—A telephone line is being put up from here to St. Augustine, which is thirty-five miles east, via Melrose, ten miles east, and Chireno, twenty miles. It was inaugurated by a stock company under the leadership of Mr. John T. White.

DENVER, COLO.—The Denver Telephone Company has filed an application with the board of public works for authority to excavate and lay a conduit for their lines in the avedp portion of the city and for permission to erect poles for telephone lines in the unpaved part of the city.

See further, page xiii.

ELECTRIC LIGHT.

CHICAGO, ILL.—The Deputy Sheriff, Dunphy, received an attachment for $8,812 against the Jonathan Clark & Sons Company, of Chicago, in favor of the Western Electric Company for balance claimed to be due on putting an electric light plant in the Park Building at Pittsburg, Pa. It was served on a third party in New York who said there was enough money in his hands to pay the attachment in full.

PORTSMOUTH, N. H.—The Portsmouth navy yard is to have an electric lighting plant.

JACKSONVILLE, FLA.—It is reported that Arthur T. Parker and H. C. Bullard, trustees for the Union Trust Company, who purchased the plant of the Jacksonville Electric Light Company, will take steps immediately towards rebuilding the plant.

WASHINGTON, N. C.—This town contemplates putting in an elecric light plant in the next 60 days. S. T. Nicholson is mayor.

FLATONIA, TEX.—The people of this city would be glad to have some company put in an electric light plant. R. O. Faires is mayor.

GAFFNEY, S. C.—The sum of $2,000 has been appropriated for additional arc lamps.

See further page xiv.

THE ELECTRICAL ENGINEER.

203 Broadway, New York.

Patented.

No. 11 Double Groeve Pony Insulater

HIGH INSULATION.

The most perfect Glass Insulator made is the Teat Insulator.

"The Teats on the lower rim of the petticoat attract the water on the outer and inner surfaces of the Insulator into drops. The water drops from these points onto the cross arm, thereby preventing the moisture from creeping to the pin."

HEMINGRAY GLASS CO., Covington, Ky.

FACTORIES, MUNCIE, IND.

MISCELLANEOUS.

FLEMINGTON, N. J.—The village trustees have passed an ordinance forbidding the stretching of telegraph, telephone or electric light wires along or across the streets of Flemington, unless permission in writing is first obtained.

ST. LOUIS, MO.—The General Electric Development Company of Bernalillo County has been formed. Incorporators: Harry Johnson, Edward A. Pearson and John Tascher. Capital stock, $250,000.

SILVER CITY, IDAHO.—The Trade Dollar mine has recently entered into a contract with a Denver firm for an electric power plant. This plant will furnish drill power for extending the works below the main tunnel, which is 1,200 feet below the apex of the mountain.

ELECTRIC LIGHT.

MARION, S. C.—An electric light plant is being put in by J. E. Duval, of Charlotte, N. C.

OSWEGO, N. Y.—The People's Electric Light and Power Company are increasing the capacity of their plant.

OPHIR, COLO.—An electric light system is be established here. Surveys have already been made. Power will be brought from the Nunn power plant at Ames, which supplies the power for the surrounding country and the Telurlde district.

MILLBURN, N. J.—The Millburn Electric Company has commenced work by erecting electric light poles along Millburn avenue.

ORANGE, TEX.—An accident to the electric light station has occurred. Loss estimated at $5,000; insured in Hartford Steam Boiler Company.

WASHINGTON, D. C.—At the regular meeting of the board of directors of the United States Electric Lighting Company, the following officers were elected: President, A. A. Thomas; first vice-president, ames L. Norris; second vice-president, Dr. Thomas O. Hills; secretary, Seymour W. Tulloch; treasurer, John W. McCartney; cashier, Edward S. Marlow.

AMHERST, MASS.—The new electric light station has been completed and put in operation.

ELECTRIC RAILWAYS.

CHARLESTON, S. C.—The Enterprise Railroad Co. has decided to use the trolley system on its lines. T. W. Passailaigue is president. The company controls thirteen and one-half miles of line.

KANSAS CITY, MO.—The West Side Street Railway Co., it is reported, is about to begin operations on its electric line. It has deposited a forfeit to insure the completion of the work.

KANSAS CITY, MO.—The Northeast Electric Railway Company has been formed; capital, $250.000. Incorporators: Edmund G. Vaughan, Samuel M. Jarvis and Milton Moore.

PHILADELPHIA, PA.—The Calhoun street bridge has been purchased by a syndicate headed by Col. Edward V. Morrell for $120,000, and it is said that it will be used by the proposed electric road which is to run from Philadelphia to Trenton.

RANDOLPH, MASS.—The Randolph, Fall Brook & Nantasket Beach Street Railway Co. has been incorporated, with a capital stock of $13,800, to build a line 5½ miles in length.

HOMESTEAD, PA.—The Homestead and Highlands electric line will be extended from Munhall to the Rankin bridge at once. The extension will be over two miles long, and the estimated cost is $50,000.

FORT WORTH, TEX.—The Glenwood & Polytechnic Co. has bought the Samuels avenue line of the City Railway and will extend and repair it. J. T. Voss is president.

BUFFALO, N. Y.—The Buffalo Traction Co. have bought out the Buffalo, Kenmore and Tonawanda R. R., an electric road 10 miles in length. They will add 66 miles of track to the Buffalo end of the line.

OSHKOSH, WIS.—The franchise and effects of the Central Wisconsin Electric Railway have been sold at auction. W. H. Clark, of Chicago, was one of the purchasers.

TELEPHONE.

MERIDIAN, MISS.—A telephone line from Meridian to Hattiesburg will be completed at an early date. This line will be about 100 miles long and will connect the following New Orleans and Northeastern Railroad towns: Meridian, Enterprise, Pachuta, Vosburg, Heidelberg, Sandersville, Laurel, Ellisville, Melrose, Eastabuchie, and Hattiesburg.

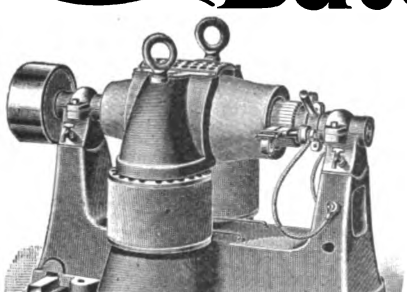
ALBANY, N. Y.—At the annual meeting of the stockholders of The Home Standard Telehone Company, the directors elected the following officers: President, John M. Bailey; first vice, James Rooney; second do., Henry Russell; secretary, Charles L. A. Whitney; and treasurer, Howard Hendrickson.

SAN JOSE, CAL.—Articles incorporating the People's Telephone Company have been filed with the County Clerk. The capital stock is placed at $50,000, of which $525 has been subscribed. The object of the corporation is to carry on a general telephone business in San Jose and vicinity. George E. Crothers, Elmer E. Chase, H. J. B. Wright, C. F. W. Herrmann and Ernest P. Lion are the incorporators.

TOLEDO, O.—The exchange of the Central Union Telephone Co. has been removed to the Spitzer Building, where new apparatus has been installed with a great increase in the rapidity and efficiency of the service.

LOCKPORT, N. Y.—According to a reliable report, the Bell Telephone Company is planning to spend a large sum of money in this city in various improvements, including the construction of a telephone exchange building, which is to cost about $10,000.

See further page xxii.



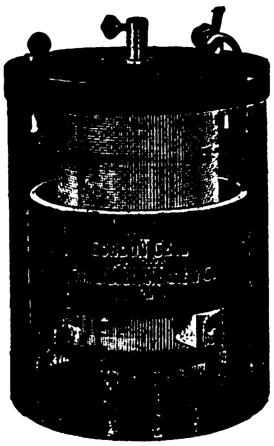
ELECTRIC RAILWAYS.

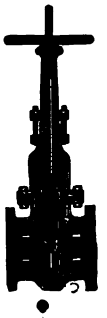
ROSSVILLE, GA.—An application has been filed in the State of Georgia for a charter for the Chattanooga Rapid Transit Co. Among the incorporators are: Samuel W. Divine, W. B. Royster, Charles D. Divine, John W. Wyatt and others, of Hamilton County, Tennessee; J. A. McFarland and R. B. Stegall, of Walker County, Georgia. The incorporators propose to build an electric line from near Rossville, Ga., in a southern direction for ten miles through Catoosa and Walker Counties, but no definite plans have been decided upon. The capital stock of the new company will probably be $150,000.

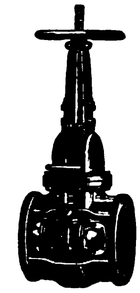
BRISTOL, PA.—The electric road has been completed from Langhorne to Bristol. The fare between the two towns has been fixed at 15 cents and 25 cents for the round trip. The steam railroad fare for the round trip between Bristol and Doylestown is now $2.20, but the distance has been shortened about 30 miles by the new electric line so that the round trip can be made for $1.78. The road is about 8½ miles in length.

CINCINNATI, O.—The Cincinnati & Miami Valley Traction Co. has been incorporated with a capital stock of $650,000. The line will be built from the present terminus of the lines of the Dayton Traction Co. at Miamisburg, through Middletown to the court house in Hamilton. The contract has been made with Messrs. Stern & Silverman, Philadelphia, for the building of the road, including the road-bed, cars, overhead construction, power stations and car barns, and they have agreed that it will be completed by July 1, 1897.

See further, page xxv.







TELEPHONE.

DUNKIRK, N. Y.—E. E. Summery, of Buffalo, has been in the city in the interests of the Automatic Telephone Company to organize a local company in this city and Fredonia, for which a charter was granted several months ago. He expects that the work of construction will begin about Jan. 1.

SOUTH ORANGE, N. J.—The Orange Telephone Company's application for a franchise to string wires in the township was referred to a committee.

NATCHEZ, MISS.—The projectors of the telephone company, viz., Lemuel P. Conner, W. P. Stewart, A. G. Campbell, James Farrell, J. A. Clinton and J. O. French, have presented their acceptance of the telephone ordinance and franchise.

BEAUMONT, TEX.—The East Texas Telephone Company has been formed at Beaumont; capital stock, $5,000. Directors: C. A. Epping, T. E. Spotswood, R. E. Lundy, and C. E. Jones.

CAMDEN, N. J.—The Camden Telephone Company, which was recently incorporated, is seeking franchise to construct lines through Camden. The company's capital stock is $250,000, and it is said that $85,000 has been paid in. The incorporators names are Chas. F. Ludington and R. D. Kelly, of Jersey City, and Clarence W. Hughes, of Brooklyn.

ELKTON, MD.—The Cecil Telephone Company, with all its fixtures, was sold at an assignee's sale, to R. C. Levis, of Elkton, for $600.
